WITHINGTON, C. F., M. D.
WOODBURY, FRANK, M. D.

INDEX TO VOLUME CVII.

THE Index of the Boston Medical and Surgical Journal is arranged by authors and by subjects. Articles relating to the circulatory, respiratory, or nervous systems are to be found under those heads respectively. This method of indexing is that followed by the Editors of the *Index Medicus*, and is believed to be the most satisfactory plan which can be adopted. F. H. B.

Abscess. A case of abscess discharging at the umbilicus in an infant, Stickney, C. W., 102; trephining for intra-cranial abscess, 214; a case of hepatic abscess, Galloupe, I. F., 271; deep abscess of the thigh, Cheever, D W., 343, 348; abdominal abscess, Gannett, W. W., 393; old abscess discharging through the urethra, Osgood, H., 491.

Adams, J. F. A. Letter from St. Augustine, Florida, 285.

Adulteration. The Massachusetts law to prevent the adulteration of food and drugs, 475; report upon the inspection and adulteration of food and drugs, Davenport, 557.

Alcoholism. The treatment of delirium tremens, 213; the treatment of delirium tremens, Ayer, J. B., 326.

Algiers. Syphilitic inoculation at Algiers, 94.

Allen, D. P. Comparison of antiseptic and non-antiseptic methods of treatment, 582.

Allen, H. Asymmetry of the nasal chambers, 520.

Allochiria: its nature and seat, Hammond, W. A., 58.

Allport, W. W. Amaurosis dependent on dental irritation, 615.

Anatomy. Appointment of Dr. Oliver Wendell Holmes emeritus professor of anatomy in Harvard University, 46; the weight and development of the brain as indicative of intellectual development, 184; recent progress in anatomy, Dwight, T., 319.

Anderson, T. McC. Paget's disease of the nipple, 94.

Aneurism of the descending aorta, Morgan, J. H., 16; death from rupture of an aneurism of the splenic artery, Ayer, J. B., 148, 155; cases of aneurism, Hinsdale, G., 420.

Animals. Medical care as practiced by animals on themselves, 333.

Anteflexion of the uterus, its ætiology and associated pathological conditions, Wylie, W. G., 398.

Anthropometry in the army, 305.

Antiseptic. Comparison of antiseptic and non-antiseptic methods of treatment, Allen, D. P., 582.

Antwerp. Letter from Antwerp, Walton, G. L., 428.

Aorta. Aneurism of the descending aorta, Morgan, J. H., 16.

Apartment Houses in New York, 280.

Apomorphia. Poisoning by apomorphia, Pécholier, 333.

Appel, D. M. The vaginal douche, 190.

Army. The Army Medical Museum and Library of the Surgeon-General's Office at Washington, 20; the appropriation for the Army Medical Library, 278; anthropometry in the army, 305.

Arsenic. Arsenical paralysis, Mills, C. K., 248, 269; arsenic in kindergarten papers, 329.

Asch, M. J. A case of sudden death occurring after tracheotomy, with remarks, 522.

Athletic Sports. Regulation of athletic sports at Harvard University, 114.

Atherton, A. B. Cases of internal strangulation of the bowels, laparotomy, 531, 553.

Atkinson (Philadelphia). Remarkable case of defective development, 310.

Atlee, J. L. Annual address before the American Medical Association, 566.

Auscultation. Misleading cardiac murmurs and expiratory auscultation of the heart, Osgood, H., 289, 296.

Autogenesis of cysticerci, 70.

Ayer, J. B. Death from rupture of an aneurism of the splenic artery, 148, 155; the treatment of delirium tremens, 326.

Bacillus Tuberculosis and the contagiousness of phthisis, 235; Ernst, H. C., 297; Mr. Watson Cheyne and the tubercle bacillus, 353.

Barker, F. A toast from Dr. Fordyce Barker to Drs. Holmes and Bigelow, 45.

Barton, J. R. Report of case of resection of radius in 1828, Hopkins, W. B., 436.

Basilysis. Professor Simpson on basilysis, 357.

Beach, H. H. A. Recent progress in surgery, 7.

Beifeld, W. T. Cartwright lecture on the relations of fungi to disease, 210.

Bell, A. G. Induction balance and electric probe for bullets, 181; Bell's induction balance and electric probe for the detection of bullets within the body, Bowditch, H. P., 276.

Bell, C. The legal rights of the insane, and their enforcement, 133.

Bell, J. A form of loss of memory occasionally following cranial injuries, 382.

Bennett, A. Mechanical restraints in the treatment of the insane, 594.

Berlin. A letter from Berlin, 261; polyclinic, 501; the Hygienic Council at Berlin, 525.

Bibliography. Allegemeinen Deutschen Ausstellung auf dem Gebiete der Hygiene und des Rettungswesens, Officieller Katalog der, 594; Allen, H., A System of Human Anatomy, including its Medical and Surgical Relation, 39, 375; American Institutions for Idiotic and Feeble-Minded Persons, Proceedings of the Association of Medical Officers, 376; American Medical Association, Transactions, Vol. XXXIII., 474; Anderson, J. W., Lectures on Medical Nursing, 497; Army, The Medical and Surgical History of the War of the Rebellion, Part III. of Vol. II., 328; Aveling, J. H., The Chamberlens and the Midwifery Forceps, 40; Beard, G. M., Herbert Spencer on American Nervousness, 278; Blodgett, A. N., The Management of Chronic Inebriates and Insane Drunkards, 208; Brown, J., Leisure Hours, Third Series, 139; Carpenter, W. M., An Index of the Practice of Medicine, 327; Courty, A., A Practical Treatise of the Diseases of the Uterus, Ovaries, and Fallopian Tubes, 135; Delafield, F., Studies in Pathological Anatomy, 160; Edwards, J. F., How we Ought to Live, 136; Esmarch, F., Early Aid in Injuries and Accidents, 160; Farquharson, R., A Guide to Therapeutics and Materia Medica, 39; Fenner, C. S., Vision, Its Optical Defects and the Adaptation of Spectacles, 571; Garrigues, H. J., Diagnosis of Ovarian Cysts by Means of the Examination of their Contents, 424; Harley, G., The Diseases of the Liver, with and without Jaundice, with Special Application of Physiological Chemistry to their Diagnosis and Treatment, 376; Hart, Mrs. E., Dr. Norris's Third Corpuscle of the Blood, 43; Hart, D. B., Manual of Gynæcology, 359; Harvard University, Annual Report of the President and Treasurer, 1881-1882, 90; Hermann, L., Experimental Pharmacology, 233; Hyde, J. N., a Practical Treatise on Diseases of the Skin, 352; Illinois, Transactions of the Thirty-Second Annual Meeting of the Illinois State Medical Society, 278; Index Medicus, 329; Jeancon, J. A., Pathological Anatomy, Pathology, and Physical Diagnosis, 160; Kay Jennings, C. E., Transfusion, its History, Indications, and Modes of Application, 447; Klein, C. H. von, A Manual of Medical Jurisprudence, 89; Klein, C. H. von, Tabulæ Anatomica Osteologicæ, 399; Kirkbride, T. S., Report of the Pennsylvania Hospital for the Insane, 207; Lewin, L., The Untoward Effect of Drugs, A Pharmacological and Clinical Manual, 594; Martin, G. H. N., and Moale, W. A., Handbook of Vertebrate Dissection, 399; Massachusetts, Annual Report of the Adjutant General, Pub. Doc. No. 7, 424; Massachusetts Institute of Technology, Eighteenth Annual Catalogue, 89; Massachusetts Board of Health, Lunacy, and Charity, Supplementary Report of Health Department, 20; Massachusetts General Hospital and McLean Asylum, Sixty-ninth Annual Report, 400; Missouri, Transactions of the Medical Association of the State of Missouri at its Twenty-fifth Annual Session, 160; New Hampshire, First Annual Report of the State Board of Health of the State of New Hampshire, 160; New York State Board of Charities, Annual Report, 91; Noyes, H. D., A Treatise on Diseases of the Eye, 352; Ohio State Medical Society, Transactions of the Thirty-sixth Annual Meeting, 89; Pennsylvania, Transactions of the Medical Society of the State of Pennsylvania at its Thirty-third Annual Session, 233; Pfeiffer, L., and Ruland, C., Festlentia in Nummis, 327; Pharmacopœia of the United States of America, 62; Playfair, W. S., The Systematic Treatment of Nerve Prostration and Hysteria, 257; Politzer, A Text-book of the Diseases of the Ear and Adjacent Organs, 543; Quain, R., A Dictionary of Medicine, Including General Pathology, General Therapeutics, Hygiene, and the Diseases Peculiar to Women and Children, 277; Quain's Elements of Anatomy, 496; Quarterly of Medicine and Surgery, Illustrated, 63; Rhode Island, Twenty-ninth Report upon the Births, Marriages, and Deaths in the State of Rhode Island for the Year ending December 31, 1881, 278; Roberts, J. B., Compend of Anatomy, 303; Rusta, C., Farmacopea Nazionale e Generale Materia Medica e Terapia, 303; Sanderson, I. B., University College Course of Practical Exercises in Physiology, 41; Sayre, L. A., Lectures on Orthopædic Surgery and Diseases of the Joints, 543; Stein, S. T., Die Allgemeine Elektrisation des Menschlichen Körpers, 277; Stewart, M., Pocket Therapeutics and Dose-book, 595; Tait, L., The Pathology and Treatment of Diseases of the Ovaries, 399; Tidy, C. M., Legal Medicine, 134; Troltsch, A. von, Diseases of the Ear in Children, Translated by J. Orne Green, 63; Tyson, J., A Guide to the Practical Examination of Urine, 183; Variola, 113; Wilder, B. G., and Gage, S. H., Anatomical Technology as applied to the Domestic Cat, 183; Wood, G. B., and Bache, F., The Dispensatory of the United States of America, 375; Ziegler, E., A Text Book of Pathological Anatomy and Pathogenesis, 398.

Bigelow, H. J. A reception to Drs. Holmes and Bigelow, 22; a simplified evacuator for litholapaxy, 25; a toast from Dr. Fordyce Barker to Drs. Holmes and Bigelow, 45; resolutions of the Harvard University Medical School on the resignations of Professors Holmes and Bigelow, 72.

Biography. Barnes, J. K., 355, 579, 477; Beard, G. M., 116, 325; Burnham, W., 96; Farr, W., 449; Fox, G., 73; Harsi, J., 44; King, C. H., 307; McCarthy, J. J., 502; Storer, D. H., 382; Van Buren, W. H., 305, 332; Watson, T., 19; Wilbur, H. B., 451.

Blackmail. Another case of blackmail, 166.

Bladder. Complete congenital extroversion of the bladder, Cheever, D. W., 49.

Blake, C. J. Accumulations of epidermis in the external auditory canal, 419, 433.

Blanchard, B. S. A case of pleurisy, 501.

Blindness. A prize on the prevention of blindness, 48.

Block. Resection of the lung as proposed by Dr. Block, 261.

Blodgett, A. N. Ovarian cysts, 204.

Boardman, W. E. Case of menstrual decidua, 466.

Bolles, W. P. Report in materia medica and pharmacy, 250; the medicines of to-day, 535.

Boston. Regulation of plumbing in the city of Boston, 46, 114; Boston City Hospital, cases in the service of Dr. G. B. Shattuck, 56; report of the commission to investigate the water-supply of Boston, 236.

Bosworth, F. H. Paresis of the constrictor muscles of the pharynx simulating spasmodic stricture of the œsophagus, with report of cases, 518.

Bowen, W. S. Secondary laryngeal lupoid ulceration, 17.

Bowditch, E. W. The siphoning of sewer traps, 155.

Bowditch, H. I. Nervous cough, 297; renescection versus bromides in eclampsia, 471; physical proof of chastity, 493.

Bowditch, H. P. Professor Bell's induction balance and electric probe for bullets, 181; Bell's induction balance and electric probe for the detection of bullets within the body, 276; force production, 385.
Bradford, E. H. Double osteotomy and osteoclasis, a correction, 24; a case of paralytic dislocation of the hip-joint, and other cases of infantile paralysis, with remarks on the surgical treatment of infantile paralysis, 73, 86; report on surgery of the joints and of deformities, 392; cases of rheumatic curvature of the spine, 445.
Brain. Tumor of brain, Brubaker, A. P., 87; the weight and development of the brain as indicative of intellectual force, 184; trephining for intracranial abscess, 214.
Brandeis, R. C. Catarrhal headaches and allied affections, 324.
Breast. Treatment of puerperal mastitis by iodide of lead ointment, Gaunt, T. T., 70; Paget's disease of the nipple, Anderson, T. McC., 94.
Breck, W. G. The New Lenox malaria case, 68.
Brighton. The new Home for Incurables at Brighton, 92.
Bright's Disease. Tunstall and Nash, H. M., 203.
Bromides. The superior value of bromide of sodium, Field, H. M., 438; venesection versus bromides in eclampsia, Bowditch, H. I., 471.
Brown, F. H. Address at annual dinner of Massachusetts Medical Society, 588.
Brown, J. Dr. John Brown's Leisure Hours, third series, 139.
Brown, W. S. Septicæmia in women, 254.
Brubaker, A. P. Tumor of brain, 87.
Bruen, E. P. A case of mitral obstruction with sequential lesions, 14; small tumor of the head of the pancreas, 110; the morphology of pulmonary phthisis, 228.
Bryant, W. N. Puerperal septicæmia, 411.
Buckingham, E. M. Ergot and ruptured uterus, 125, 130.
Burge, W. J. Spontaneous separation of the funis, 299.
Burial Customs in England, 430.
Burn. Case of plastic operation for a burn of the arm, Porter, C. B., 469.
Burrell, H. L. Spinal caries; abscess discharging through intestine; closure of intestinal opening; death from bursting of abscess into peritoneal cavity, 513.
Bush, J. F. Cases of intestinal obstruction treated by means of the rectal tube, 97, 103.
Butler, B. F. Governor Butler's message to the Massachusetts Legislature, 23; Governor Butler's lunacy commissioner, 65.
Byford, W. H. Chronic entero-pelvic inflammation, 612.
Byrd, W. A. Exsection of both hip-joints for morbus coxarius, 584.

Cabot, A. T. Nephrotomy for hydronephrosis; recovery, 173, 182; cases in the service of Dr. Cabot, 253; recent progress in surgery, 610.
Caffeine. A clinical study of the action and uses of caffeine and convallaria majalis as cardiac tonics, Robinson, B., 373.
Calculus of Bladder, Gay, G. W., 155.
Cameron. Glycosuria with low specific gravity, 502.
Cancer. Specimens of cancer involving the stomach, liver, pancreas, rectum, and lung, Hinsdale, G., 301.
Carcinoma following orchitis, Fuller, F. B., 16; of the stomach, Musser, J. H., 61; a case of medullary carcinoma, Homans, C. D., 444.
Caries of the ankle, Cabot, A. T., 253.
Cartwright Lectures for 1883, 210.
Casebeer, J. B. Paediatric medication and its relation to general medicine, 615.
Caswell, E. T. Litholapaxy, 17.
Catarrh. Catarrhal headaches and allied affections, Brandeis, R. C., 324.
Catheter. A necessary change in the catheter, Steensen, C., 453.
Cellular Tissue. Cellular abscess, Cheever, D. W., 49.
Cellulitis. Orbital cellulitis as a sequel of facial erysipelas, Williams, H. W., 61, 67.
Censors. Conference of Board of Censors, Massachusetts Medical Society, 617.
Centenarian, 334.
Channing, W. Medical treatment of insanity, with special reference to opium, 86.
Chastity. Physical proof of chastity, Bowditch, H. I., 493.
Cheever, D. W. Clinical lecture: cellular abscess; punctured wound of hand; ligature of the brachial artery; ulcer of the upper lip; acute synovitis of the wrist; complete congenital extroversion of the bladder, 49; deep abscess of the thigh, 343, 348.
Chemistry. Recent progress in medical chemistry, Hills, W. B., 177.
Cheyne, W. Mr. Watson Cheyne and the tubercle bacillus, 353.
Children. Recent progress in diseases of children, Rotch, T. M., 80, 126; artificial feeding for infants, Meigs, A. V., 118; opening lecture on diseases of children at the Post-Graduate Medical School, New York, 121, 145; acute infantile peritonitis, Rotch, T. M., 208, 274; erysipelas neonatorum, Fisher, H. M., 350; activity of the senses in new-born infants, 454; hereditary syphilis and idiocy or juvenile dementia, 498; undiluted milk for infants, 626; recipes for artificial feeding, 550; cephalhæmatoma in the new born, Earle, C. W., 614; epidemic jaundice among children, Garnett, A. T. P., 614; dentition, Good, A. H., 614; paediatric medication and its relation to general medicine, Casebeer, J. B., 615.
Chloroform. The criminal use of chloroform, 595.
Cholera Morbus, Stephenson, F. B., 302; "winter cholera," 382.
Chondroma of the skull, Griffith, J. P. C., 349.
Chorea. Notes on a case of acute chorea associated with profound mental disturbance, Stedman, H. R., 76, 86; chorea laryngis, Knight, F. I., 517.
Circulatory System. On overwork and strain of the heart, Germain-See, 1; a case of mitral obstruction with sequential lesions, Bruen, E. P., 14; pericardial effusion and adhesion of the pericardium to the apex of the heart mistaken for heart rupture, Eskridge, J. T., 14; aneurism of the descending aorta, Morgan, J. H., 16; stab of pericardium, diaphragm, and liver, Stuttmatter, 33; idiopathic endocarditis, Fifield, W. C. B., 36; heart puncture and heart sutures as therapeutic procedures, Roberts, J. B., 79; death in old age from cardiac syncope, with lesion of bowels presenting symptoms of inflammation, Stephenson, F. B., 88; death from rupture of an aneurism of the splenic artery, Ayer, J. B., 148, 155; misleading cardiac murmurs and expiratory auscultation of the heart, Osgood, H., 289, 296; a unique specimen of ossification at the aortic orifice, Eskridge, J. T., 329; embolism of the left middle cerebral artery, accompanied by aphasia and agraphia, Lyman, G. H., 371, 388; cases of aneurism, Hinsdale, G., 420; two cases of fatal heart trouble, with complications, Shattuck, F. C., 467; specimens (lungs, heart, and kidneys) from a case of Bright's disease, Henry, F. P., 515; laryngeal paralysis from aneurism, Porter, W., 519; carcinoma of the stomach and colon with cardiac lesions, Eskridge, J. T., 539; mitral stenosis and regurgitation formed by tricuspid regurgitation and general dropsy, Eskridge, J. T., 540; congenital malformation of the heart with cyanosis, Eskridge, J. T., 541.
Clark, T. M. Plumbing appliances, 586, 596.
Cleveland. Letter from Cleveland, 573.
Clouston, T. S. Female education in relation to its mental and physical results, 68.
"Cod Oil." How they make "cod oil" at Swampscott, 238.
Colotomy. Two cases of colotomy, Warren, J. C., 172, 181; a case of left lumbar colotomy with recovery, Smith, F. L., 318.
Common Sense in the practice of medicine, 523.
Concussion. The true significance of some of the prominent symptoms of so-called spinal concussion, Putnam, J. J., 491.
Consumption. Concerning Newport, R. I., as a resort for consumptives, Tyndale, J. H., 188, 231, 452; Storer, H. R., 282, 404; New Mexico, its climatic advantages for consumptives, Tyndale, J. H., 265, 313; consumption in New England, Hurd, E. P., 292, 316, 481.
Convallaria Majalis, the other side, 190; experiments upon rabbits, 214; a clinical study of the action and uses of caffeine and convallaria majalis as cardiac tonics, Robinson, B., 373.
Corkhill, G. B. Insanity as a defense for crime, 447.
Coroners. The office and duties of coroners, Palmer, W. H., 16.
Croup. Croupous inflammation of the pharynx, larynx, and trachea, with occlusion of the larger bronchi, Draper, F. W., 204; unity of diphtheria and membranous croup, Harris, A., 614.
Cummings, E. F. A case of congenital malformation of the genital organs, 136, 201.
Cutaneous System. Leprosy. A case in Salem, Massachusetts, 18; Hawaiian and Norwegian leprosy, 353; report on diseases of the skin, Tilden, G. H., 415; a case of obscure, rapidly fatal disease attended by extensive painful tumefactions of the skin, Greene, J. S., 462, 470; mechanical remedies in the treatment of skin diseases, Shoemaker, J. V., 585.
Cysticercus. Autogenesis of cysticerci, 70.

Dana, C. L. Hydrobromic acid as a substitute for the bromides, .
Darling, A. E. Notes on a case of pleurisy with an unusual amount of effusion, 443.
Davenport, B. F. The new pharmacopœia, 105; report upon the inspection and adulteration of food and drugs, 557.
Davenport, F. H. Recent progress in gynæcology, 54.
Death. On sudden death by the entrance of air into the uterine veins, Draper, F. W., 3, 28; death from rupture of an aneurism of the splenic artery, Ayer, J. B., 148, 155; the decline in the death-rate and increased duration of life in England, 545.
Defective Development. Remarkable case, Atkinson, 310.
Delavan, D. B. The lacunæ tonsillaris, 522.
Delirium Tremens. The treatment of delirium tremens, 213; the treatment of delirium tremens, Ayer, J. B., 326.
Dentistry. Enamel fillings for teeth, Rollins, W. H., 391; yearly report on dentistry, Rollins, W. H., 511; dentition, Good, A. H., 614; denudation or erosion of the teeth, Marshall, J. S., 615; pyrrhœa alveolaris, Marshall, J., 615; amaurosis dependent on dental irritation, Allport, W. W., 615.
Diabetes. Diabetic coma, 401; glycosuria, with low specific gravity, Cameron, 502.
Diet in the treatment of the gouty dyscrasia, Draper, W. H., 205.
Digestive System. Perityphlitis, Noyes, R. F., 17; stab of pericardium, diaphragm, and liver, Stuttmatter, 33; membrane from intestine, Goss, F. W., 35; tuberculosis of spleen, liver, and kidneys, Shakespeare, 59; two cases of carcinoma of the stomach, Musser, J. H., 61; cases of intestinal obstruction treated by means of the rectal tube, 97, 103; small tumor of the head of the pancreas, Bruen, E. T., 110; diaphragmatic hernia, Tyson, J., 110; ulcer of the stomach in the anterior wall, adhesions to the abdominal wall, hæmorrhages and pain, death from morphia habit, Musser, J. H., 111; two cases of colotomy, Warren, J. C., 172, 181; a remarkable case of glass swallowing, 214; acute dilatation of the stomach occurring in surgical cases, Fifield, W. C. B., 228; a case of hepatic abscess, Goodspeed, F., 271; acute infantile peritonitis, Rotch, T. M., 268, 274; strangulated umbilical hernia, Gannett, W. W., 297; specimens of cancer involving the stomach, liver, pancreas, rectum, and lung, Hinsdale, G., 301; cholera morbus, Stephenson, F. B., 302; a case of left lumbar colotomy, with recovery, Smith, F. L., 318; multiple contractures of the small and the large intestine following enteritis, Stedman, C. E., 391, 396; abscess, Gannett, W. W., 398; diabetic coma, 401; appearance of altered banana in the dejections, Edes, R. T., 446; yearly report on dentistry, Rollins, W. H., 511; the swallowing of a silver half dollar, death, Webster, C. E., 513; cases of internal strangulation of the bowels, laparotomy, Atherton, A. B., 531, 553; carcinoma of the stomach and colon, with cardiac lesions, Eskridge, J. T., 539; surgical treatment of intestinal obstruction, Marcy, H. O., 584; alimentary canal in bronchitis and phthisis, Reynolds, T. N., 585; dentition, Good, A. H., 614; denudation or erosion of the teeth, Marshall, J. S., 615; pyrrhœa alveolaris, Marshall, J., 615; amaurosis dependent on dental irritation, Allport, W. W., 615.
Dilatation of the stomach occurring in surgical cases, Fifield, W. C. B., 238.
Diphtheria spread by milk, 549; unity of diphtheria and membranous croup, Harris, A., 614.
Diplomas. Diploma-tization, 20; free trade in diplomas, 234.
Disinfection in typhoid fever, 22; compulsory disinfection of typhoid excreta, 43; the typhoid epidemics of the last decade and the necessity of compulsory disinfection, Prince, M., 153, 193.
Dislocation. Treatment of old cases of compound dislocation of the ulna in conjunction with Colles' fracture, Moore, E. M., 585.
Donaldson, F. The destruction of nasal polypi by chromic acid, 517.
Draper, F. W. On sudden death by the entrance of air into the uterine veins, 3, 28; recent progress in forensic medicine, 149; croupous inflammation of the pharynx, larynx, and trachea, with occlusion of the larger bronchi, 204.
Draper, W. H. Diet in the treatment of the gouty dyscrasia, 205
Dresden. Notes on the lying-in hospitals of Vienna, Dresden, and Prague, Lombard, F. H., 606.
Dujardin-Beaumetz. On Hydrotherapeutics, 169; on medical electricity, 397.
Dunn, W. A. Emphysema occurring during labor, 397.
Dwight, T. Recent progress in anatomy; 319.

Ear. The action of quinine upon the ear, Green, J. Orne, 220, 226; Earache in measles, Theobald, 310; accumulations of epidermis in the external auditory canal, Blake, C. J., 419, 433; the effect of noise on healthy

and diseased ears, Roosa, D. B. St. J., 422; otitis media purulenta, Spear, E. D., 485, 492; tympanic caries producing sub-dural abscess opening into lateral sinus, 514; aural complications of inflammatory conditions of the nose and throat, Robinson, B., 522; the functions of the semicircular canals, McBride, P., 559; recent progress in otology, Green, J. Orne, 581; tinnitus aurium and deafness which accompanies the different forms of Bright's disease, Turnbull, L., 616.

Earle, C. W. Cephalhæmatoma in the new born, 614.

Edes, R. T. Experiments with artificial digestive agents, 277; appearance of altered banana in the dejections, 445.

Editorials. 1883, 18; leprosy, a case in Salem, Massachusetts, 18; Sir Thomas Watson, M. D., F. R. S., 19; the Army Medical Museum and Library of the Surgeon-General's office at Washington, 20; supplementary report of Health Department of Massachusetts Board of Health, Lunacy, and Charity, 20; diploma-tization, 20; Governor Butler's message to the Massachusetts Legislature, 42; routine practice, 42; the compulsory disinfection of typhoid excreta, 43; Dr. Robert Koch's latest estimate of Pasteur's methods and discoveries and of the present position of the general inoculation problem, 64; Governor Butler's lunacy commissioner, 65; Sir James Paget on some rare and new diseases, 66; annual report of the President and Treasurer of Harvard University, 1881-1882, 90; annual report of the New York State Board of Charities, 91; the new Home for Incurables at Brighton, 92; trustees of State lunatic hospitals, 92; regulation of Plumbing in Boston, 114; regulation of athletic sports at Harvard University, 114; Philadelphia water supply, 115; subjects for master's degree at Harvard, 1655-1791, 137; new departure in the Boston Medical Library Association, 138; an Italian hospital in New York, 138; Dr. John Brown's Leisure Hours, third series, 139; the meeting of the New York State Medical Society, and its Code of Ethics, 161; the Hounslow suicide, 162; the water supply of New York, 163; the weight and development of the brain as indicative of intellectual force, 184; hydriatry, 185; the financial problem in the English hospitals, 186; Pasteur's reply to Koch, 209; defective vision among railroad employees; attempt to prevent examinations, 209; the Cartwright lectures for 1883, 210; the New York Code, 210; free trade in diplomas, 234; what may reasonably be expected from more instruction in mental diseases, 235; the bacillus tuberculosis and the contagiousness of phthisis, 235; report of the commission to investigate the water supply of Boston, 236; water pollution and chemical analysis, 257; medical legislation in Pennsylvania, 258; amateur therapeutics, 259; poor-house treatment for lunatics, 279; apartment houses in New York, 280; the water supply of New York City, 304; school hygiene, provision therefor in Illinois, 304; a flimsy suit for malpractice, 305; anthropometry in the army, 305; election of delegates in favor of the old Code of Ethics to the New York State Medical Society, 328; the Medical and Surgical History of the War of the Rebellion, Part III. of vol. ii., 328; the Index Medicus, 329; Hawaiian and Norwegian leprosy, 353; Mr. Watson Cheyne and the tubercle bacillus, 353; the causes and prevention of the pollution of streams; the King of Saxony's prize, 355; the "images" suit, 377; the New York dinner to Dr. Holmes, 378; Surgeon-General Barnes, 379; sixty-ninth annual report of trustees of the Massachusetts General Hospital and McLean Asylum, 1882, 400; diabetic coma, 400; an outbreak of typhoid fever, 402; the care of insane criminals, 425; hereditary syphilis and rickets, 426; the sea-shore home, 427; typhoid versus typhus fever, 448; sanitary and medical legislation in New Jersey, 448; International Congress of Colonial Physicians, 449; the water supply of New York, 449; Dr. William Farr, F. R. S., 449; discharged lunatics, 474; the Massachusetts law to prevent the adulteration of food and drugs, 475; a fire in the new building of the Harvard Medical School, 476; disease of the optic disk following typhoid fever, 476; the British Medical Association, 476; hereditary syphilis and idiocy, or juvenile dementia, 498; the Warren triennial prize, 499; suicide made easy, 499; the one hundred and second anniversary of the Massachusetts Medical Society, 499; common sense in the practice of medicine, 523; regulation of the practice of medicine in Illinois and New Hampshire, 523; the hygienic exhibition at Berlin, 525; the decline in the death-rate and increased duration of life in England, 545; a model house, 546; the notification of measles, 547; the American Medical Association, 571; the one hundred and second anniversary of the Massachusetts Medical Society, 572; physicians' vacations, 572; the protection of man in malarious countries, 595; the criminal use of chloroform, 595; the proper and faulty methods of plumbing, drainage, and ventilation, 596; disease and crime, 623.

Education. Female education in relation to its mental and physical results, Clouston, T. S., 68; the duty of medical colleges and the general practitioners towards mental and nervous diseases, Mills, C. K., 132; schools of medicine, 190; what may reasonably be expected from more instruction in mental diseases, 235; a description of the new building erected for the medical school of Harvard University, 339; report of a summer course in obstetrics, Green, C. M., 424; the study of physiology in a veterinary school, 453; a fire in the new building of the Harvard Medical School, 476; medical education, the fundamental fact in medical ethics, Gihon, A. L., 615.

Elaterium. Note upon crystalline elaterin. Griswold, G., 398.

Electric Probe for bullets, Bell, A. G., 181, 276.

Electricity. The differential indications for the use of dynamic and Franklinic or static electricity, Rockwell, A. D., 108; Franklinism or atmospheric electricity as a remedy, Garratt, A. C., 123; electric storage works and lead poisoning, 213; on medical electricity, Dujardin-Beaumetz, 337.

Eliot, C. W. Address at annual dinner of Massachusetts Medical Society, 590.

Ellis, F. W. Ingluvin, 381.

Elsberg, L. Reflex phenomena due to nasal disease, 519.

Embryology. The fœtal envelopes, Minot, C. S., 409.

Emergency lectures, 310.

Empyema. A case of empyema, Richardson, M. H., 555.

Enamel fillings for teeth, Rollins, W. H., 391.

Endocarditis. Idiopathic endocarditis, Fifield, W. C. B., 36.

English Hospitals. The financial problem in the English hospitals, 186.

Enteric Fever. Disinfection in typhoid fever, 22; compulsory disinfection of typhoid excreta, 43; observations on the management of enteric fever according to a plan based upon the so-called specific treatment, Wilson, J. C., 99; the typhoid epidemics of the last decade and the necessity of compulsory disinfection, Prince, M., 153, 175, 193.

Epidemics. Some typhoid epidemics of the last decade, and the necessity of compulsory disinfection, Prince, M., 153, 175, 193.

Ergot and ruptured uterus, Buckingham, E. M., 125, 130.

Ernst, H. C. Bacillus of tuberculosis, 297.

Erysipelas. Orbital cellulitis as a sequel of facial erysipelas, Williams, H. W., 51, 57; erysipelas neonatorum. Fisher, H. M., 350.

Eskridge, J. T. Pericardial effusion and adhesion of the pericardium to the apex of the heart mistaken for heart rupture, 14; a unique specimen of ossification at the aortic orifice, 323; carcinoma of the stomach and colon, with cardiac lesions, 539; mitral stenosis and regurgitation formed by tricuspid regurgitation and general dropsy, 540; congenital malformation of the heart, with cyanosis, 541; a case of general neuralgia, 622.

Ether. The subcutaneous use of ether in hæmorrhage, Hayem, 94.

Ethics. The new Code of Ethics (New York), Sayre, L. A., 107; the meeting of the New York State Medical Society and its Code of Ethics, 161; the New York Code, 211; New York letter, 549.

Eucalyptus. Eucalyptus trees at Rome, 63.

Exsection of both hip-joints for morbus coxarius, Byrd, W. A., 584.

Extroversion of the bladder, Cheever, D. W., 49.

Eye. Several specimens of eyes enucleated on account of sympathetic irritation in the other eye or for fear of its developing, Little, 15; a prize on the prevention of blindness, 48; orbital cellulitis as a sequel of facial erysipelas, Williams, H. W., 51, 57; treatment of diseases of the lachrymal canal, Williams, C. H., 159; defective vision among railroad employees, attempt to prevent examinations, 209; ocular symptoms as localizing symptoms, Webber, S. G., 217, 226, 244; the apparent curvature of surface caused by prismatic glasses, Wadsworth, O. F., 277; simulated amaurosis,—tumors of the orbit, impairment of the retina by exposure to the sun's rays, Miller, H. J., 298; disease of the optic disk following typhoid fever, 476; recent progress in ophthalmology, Wadsworth, O. F., 532; the new treatment of granular lids by jequirity, Standish, M., 606; amaurosis dependent on dental irritation, Allport, W. W., 615.

Fatty Tumors. Two cases of very large fatty tumors within the abdomen, Homans, J., 35, 241.

Fibroid Tumor of the uterus, Fifield, M., 16.

Field, H. M. The superior value of the bromide of sodium, 438.

Fifield, M. Fibroid tumor of the uterus, 16.

Fifield, W. C. B. Idiopathic endocarditis, 36; otitis and arthritis, 155; acute dilatation of the stomach occurring in surgical cases, 228.

Fisher, H. M. Case of metastatic pneumonia following pistol-shot wound of temporal bone, 349; case of erysipelas neonatorum, 350.

Florida. Letter from St. Augustine, Adams, J. F. A., 285; letter from Florida, 286.

Food. Artificial feeding for infants, Meigs, A. V., 118; experiments with artificial digestive agents, Edes, R. T., 277.

Forensic Medicine. Recent progress in forensic medicine, Draper, F. W., 149.

Fœtus. The fœtal envelopes, Minot, C. S., 409; retrogressive history of the fœtus, Minot, C. S., 529.

Force Production. Bowditch, H. P., 385.

Fractures. The treatment of the fractures of long bones, Taylor, J. R., 584.

French, T. R. Photographing the larynx, 518.

Fuller, F. B. Carcinoma following orchitis, 16.

Fungi. The relations of fungi to disease, Belfield, W. T., 210.

Funis. Spontaneous separation of the funis, Burge, W. J., 299.

Galloupe, I. F. A case of hepatic abscess, 271.

Gannett, W. W. A case of tubal pregnancy, 155; strangulated umbilical hernia, 297; abdominal abscess, 398.

Garnett, A. T. P. Epidemic jaundice among children, 614.

Garratt, A. C. Franklinism or atmospheric electricity as a remedy, 123.

Garrigues, H. J. Gastro-elytrotomy (Thomas's operation) compared with oöphoro-hysterectomy (Porro's operation), 13; transfusion in gas-poisoning, 310.

Gaunt, T. T. Treatment of puerperal mastitis by iodide of lead ointment, 70.

Gas. A case of poisoning with illuminating gas, Mason, A. L., 196, 203; transfusion in gas-poisoning, Garrigues, H. J., 310.

Gay. Calculus of bladder, 155.

General Diseases. Carcinoma following orchitis, Fuller, F. B., 16; secondary laryngeal lupoid ulceration, Bowen, W. S., 17; secondary sarcoma of heart, lungs, and gall-bladder, following primary amputation for deposit in the femur, Willard, 24; cancer of the left kidney and lung, Goss, F. W., 57; tuberculosis of spleen, liver, and kidneys, Shakespeare, 59; two cases of carcinoma of the stomach, Musser, J. H., 61; diet in the treatment of the gouty dyscrasis, Draper, W. H., 205; specimens of cancer involving the stomach, liver, pancreas, rectum, and lung, Hinsdale, G., 391; earache in measles, Theobald, S., 310; on the existence of syphilis in America before the discovery by Columbus, Whitney, W. F., 365; hereditary syphilis and rickets, 426; typhoid versus typhus fever, 448.

Generative System. A contribution to the subject of removal of the uterine appendages (Tait's operation) for recurrent pelvic inflammations, Thomas, T. G., 12; gastro-elytrotomy (Thomas's operation) compared with oöphoro-hysterectomy (Porro's operation), Garrigues, H. J., 13; fibroid tumor of the uterus, Fifield, M., 16; carcinoma following orchitis, Fuller, F. B., 16; recent progress in gynæcology, Davenport, F. H., 54; polypi from the uterine cavity, Parrish, W. H., 88; condylomatous tumor of the labium, Seltzer, C. M., 109; ergot and ruptured uterus, Buckingham, E. M., 125, 130; Dr. Goodell on sterility and pelvic peritonitis, 142; a case of congenital malformation of the genital organs, Cummings, E. F., 195, 201; ovarian cysts, Blodgett, A. N., 206; cases of laceration of the cervix uteri occurring in the New England Hospital during the two years beginning October 1, 1880, Smith, M. A., 322; a case of inverted uterus treated by the modern method, 371, 386; anteflexion of the uterus, its ætiology and associated pathological conditions, Wylie, W. G., 398; case of menstrual decidua, Boardman, W. E., 466; physical proof of chastity, Bowditch, H. I., 493; pins in the vagina, Green, C. M., 493; contrivance for dilating the os uteri by elastic pressure, Williams, E. T., 535; chronic entero-pelvic inflammation, Byford, W. H., 612; post-partum polypoid tumors, Landis, W. H., 613; value of gynæcological treatment in hysteria and allied affections, Zenner, P., 613; midwifery and gynæcology of the ancients, Maughs, G. M., 613.

Germain-Sée. On overwork and strain of the heart, 1.

Germ Theory. The relation of the germ theory to surgical pathology, 276.

Gihon, A. L. Medical education the fundamental fact in medical ethics, 615.

Glass Swallowing, 214.

Glioma. Case of glioma of the pons varolii, Putnam, J. J., 437.

Glycosuria, with low specific gravity, Cameron, 502.
Goldsmith, W. B. Report on progress in mental diseases, 345, 369.
Good, A. H. Dentition, 614.
Goodell. Dr. Goodell on sterility and pelvic peritonitis, 142.
Goss, F. W. Membrane from intestine, 35; cancer of the left kidney and lung, 57.
Gould, B. A. Address at annual dinner of Massachusetts Medical Society, 590.
Gout. Diet in the treatment of the gouty dyscrasia, Draper, W. H., 205.
Green, C. M. Report of a summer course in obstetrics, 434; pins in the vagina, 493.
Green, J. Orne. The action of quinine upon the ear, 220, 226; recent progress in otology, 581.
Green, T. Functions of a medical staff of an insane hospital, 132.
Greene, J. S. A case of obscure and rapidly fatal disease attended by extensive painful tumefaction of the skin, 462, 470.
Griffith, J. P. C. Chondroma of the skull, 349.
Griswold, G. Note upon crystalline elaterin, 398.
Gross, S. D. Value of early and late operations in morbid growths, especially malignant, 583.
Gynæcology. Recent progress in gynæcology, Davenport, F. H., 54.

Hæmorrhage. The subcutaneous use of ether in hæmorrhage, Hayem, 94.
Hamilton, J. B. Address at annual meeting of Massachusetts Medical Society, 591.
Hammond, W. A. Allochiria, its nature and seat, 58.
Hand. Punctured wound of hand, ligature of the brachial artery, Cheever, D. W., 49.
Harris, A. Unity of diphtheria and membranous croup, 614.
Harris, F. A. A review of the evidence in the Malley trial, 361, 370.
Harvard University. Resolutions of the Harvard University Medical School on the resignations of Professors Holmes and Bigelow, 72; annual report of the President and Treasurer of Harvard University, 1881–1882, 9; regulation of athletic sports at Harvard University, 114; subjects for master's degree at Harvard, 1655–1791, 139; a description of the new building erected for the Medical School of Harvard University, 339; a fire in the new building of the Harvard Medical School, 476.
Hawaii. Hawaiian and Norwegian leprosy, 353.
Hayem. The subcutaneous use of ether in hæmorrhage, 94.
Heart. A case of mitral obstruction with sequential lesions, Bruen, E. P., 14; pericardial effusion and adhesion of the pericardium to the apex of the heart mistaken for heart rupture, Eskridge, J. T., 14; heart puncture and heart suture as therapeutic procedures, Roberts, J. B., 79.
Heffenger, A. C. A letter from Valparaiso, 164.
Henry, F. P. Specimens (lungs, heart, and kidneys) from a case of Bright's disease, 515.
Hernia. Diaphragmatic hernia, Tyson, J., 110; strangulated umbilical hernia, Gannett, W. W., 297.
Hills, W. B. Recent progress in medical chemistry, 177.
Hingston, W. H. Address at annual dinner of Massachusetts Medical Society, 591.
Hinsdale, G. Specimens of cancer involving the stomach, liver, pancreas, rectum, and lung, 301; cases of aneurism, 420.
Hip. A new frame splint for hip disease, Watson, F. S., 84, 85; compound dislocation of the hip, Woodward, R., 129.
Hip Disease. Exsection of both hip-joints for morbus coxarius, Byrd, W. A., 584.
Holmes, O. W. A reception to Drs. Holmes and Bigelow, 22; a toast from Dr. Fordyce Barker to Drs. Holmes and Bigelow, 45; appointment of Dr. Oliver Wendell Holmes Emeritus Professor of Anatomy in Harvard University, 46; resolutions of the Harvard University Medical School on the resignation of Professors Holmes and Bigelow, 72; Sweet Holmes! 86; the New York dinner to Dr. Holmes, 378, 379.
Homans, C. D. Wound of perinæum extending into vagina, compound separation of symphysis pubis, with protrusion of the bladder, 344, 347; a case of medullary carcinoma, 444.
Homans, J. Two cases of removal of immense fatty tumors by abdominal section, 35, 241.
Hooper. Stenosis of the larynx, 36.
Hooper, F. H. Experimental researches on the tension of the vocal bands, 521.
Hopkins, W. B. Report of a case of resection of the radius performed by Dr. John Rhea Barton in 1826, 436.
Horton, E. A. Address at annual dinner of Massachusetts Medical Society, 590.
Hosmer, A. Address at annual dinner of Massachusetts Medical Society, 588.
Hounslow Suicide, 162.
Hurd, E. P. Consumption in New England, 292, 316, 481.
Hydriatry, 185.
Hydrotherapeutics. Dujardin-Beaumetz, 169; hydriatry, 186.
Hygiene, Health, and Boards of Health. Supplementary report of Health Department of Massachusetts Board of Health, Lunacy, and Charity, 20; disinfection in typhoid fever, 22; Governor Butler's message to the Massachusetts Legislature, 42; compulsory disinfection of typhoid excreta, 43; regulation of plumbing in the city of Boston, 46, 114; Philadelphia water supply, 115; the typhoid epidemics of the last decade and the necessity of compulsory disinfection, Prince, M., 153, 193; New York State Board of Health; rulings as to mixtures, 166; school hygiene, provision therefor in Ohio, 304; typhoid versus typhus fever, 448; sanitary and medical legislation in New Jersey, 448; the Hygienic Congress at Berlin, 525; a model house, 546; the proper and faulty methods of plumbing, drainage, and ventilation, Clark, T. M., 586, 596; the meeting of the Illinois State Board of Health, Johnson, H. A., 616; disease and crime, 628.
Hysteria. Value of gynæcological treatment in hysteria and allied affections, Landis, W. H., 613.

Illinois. Regulation of the practice of medicine in Illinois and New Hampshire, 523; State Board of Health, 616
Infantile Paralysis. A case of paralytic dislocation of the hip-joint, and other cases of infantile paralysis, with remarks on the surgical treatment of infantile paralysis, Bradford, E. H., 73, 86.
Ingalls, E. F. The treatment of laryngeal phthisis, 517.
Ingluvin, Ellis, F. W., 381.
Inoculation. Dr. Robert Koch's latest estimation of Pasteur's methods and discoveries and of the present position of the general inoculation problem, 64; syphilitic inoculation at Algiers, 94; Pasteur's reply to Koch, 209.
Insane. The obligations of society to the insane, Newton, H., 594; mechanical restraints in the treatment of the insane, Bennett, A., 594.
Insanity. Medical treatment of insanity with special reference to opium, Channing, W., 86; functions of a medical staff of an insane hospital, Green, T., 132; the duty of medical colleges and the general practitioners towards mental and nervous diseases, Mills, C. K., 132; how to protect the insane, Parrish, J., 132; the legal rights of the insane and their enforcement, Bell, C., 133; poor-house treatment for lunatics, 279.
Instruments and Apparatus. A simplified evacuator for litholapaxy, Bigelow, H. J., 25; a new frame splint for hip disease, Watson, F. S., 84, 85; the vaginal douche, Appel, D. M., 190; new instrument for the operation of tracheotomy, Otis, W. J., 348, 396; a new tongue depressor, Parker, W. T., 444; a necessary change in the catheter, Steensen, C., 453; contrivance for dilating the os uteri by elastic pressure, Williams, E. T., 535.
Incurables. The new Home for Incurables at Brighton, 92.
Indians. Pathological changes in the bones of the North American Indians, Whitney, W. F., 371.
International Congress of Colonial Physicians, 449.
Italian hospital in New York, 138.

James, P. The use of the iron salts, 263.
Jarvis, W. C. The healing of ulcers in laryngeal phthisis, 518.
Jaundice. Epidemic jaundice among children, Garnett, A. T. P., 614.
Jequirity. The new treatment of granular lids by jequirity, Standish, M., 606.
Johnson, A. H. Annual address before the Massachusetts Medical Society, 577; address at annual dinner, 589, 601.
Johnson, H. A. Congenital tumors of the larynx, with a report of cases, 518; the meeting of the Illinois State Board of Health, 616.
Jurisprudence. Medico-legal notes, 141; recent progress in forensic medicine, Draper, F. W., 149; the Hounslow suicide, 162; a review of the evidence in the Malley trial, Harris, F. A., 361, 370; the "images" suit, 377; insanity as a defense for crime, Corkhill, G. B., 447; physical proof of chastity, Bowditch, H. I., 493; suicide made easy, 499; the criminal use of chloroform, 595.

Keene, S. S. Pneumonia, 298.
Kinnear, B. O. Explanatory remarks upon neuro-dynamic medicine, with cases, 366, 370.
Klein, C. H. von. A "vindicative" letter, 189.
Knight, F. I. Recent progress in the treatment of thoracic diseases, 197, 223; chorea laryngis, 517; lympho-sarcoma of the lung, 535.
Koch, R. Dr. Robert Koch's latest estimate of Pasteur's methods and discoveries and of the present position of the general inoculation problem, 64; Pasteur's reply to Koch, 209.

Landis, W. H. Post-partum polypoid tumors, 613.
Langmaid, S. W. A common form of vocal disability, resulting from pathological processes; the phenomena used to demonstrate the falsity of one system of voice training, 516.
Laryngotomy. New facts in laryngotomy, Lefferts, G. M., 516.
Larynx. Stenosis of the larynx, Hooper, 36; secondary laryngeal lupoid ulceration, Bowen, W. S., 17; elements of prognosis and therapeutics of laryngeal tuberculosis, Solis-Cohen, J., 586.
Leeches, 454.
Lefferts, G. M. New facts in laryngotomy, 516.
Lenox. The New Lenox malaria case, Breck, W. G., 68.
Leprosy. A case in Salem, Mass., 18; Hawaiian and Norwegian leprosy, 353.
Library. Library of the surgeon-general's office at Washington, 20; new departure in the Boston Medical Library Association, 138; the appropriation for the Army Medical Library, 278.
Liebmann, G. A new treatment of venereal warts, 348.
Life. The decline in the death-rate and increased duration of life in England, 565.
Lip. Ulcer of the upper lip, Cheever, D. W., 49.
Litholapaxy. Caswell, E. T., 17; a simplified evacuator for litholapaxy, Bigelow, H. J., 25.
Little. Several specimens of eyes enucleated on account of sympathetic irritation in the other eye, or for fear of its developing, 15.
Liver. A case of hepatic abscess, Gallioupe, I. F., 271.
Lombard, F. H. Puerperal fever, prophylaxis in hospital practice, notes on the lying-in hospitals of Vienna, Dresden, and Prague, 509.
London. Letter from London, 22.
Lunacy. Governor Butler's lunacy commissioner, 65; trustees of State lunatic hospitals, 92; poor-house treatment for lunatics, 279.
Lyman, G. H. Embolism of the left middle cerebral artery, accompanied by aphasia and agraphia, 371, 388.
Lymphatic glands, enlarged, Parrish, W. H., 88.

M'Alpine, D. Practical lessons in elementary physiology and physiological anatomy, 544.
MacConnell (Philadelphia). Myxomatous tumor of the subcutaneous cellular tissue of the chest, 516.
Magnolia. Letter from Florida, 286
Major, G. W. The value of post-laryngeal papillomata as a means of diagnosis in tubercular disease, 522.
Malaria. The New Lenox malaria case, Breck, W. G., 68; eucalyptus trees at Rome, 69; the protection of man in malarious countries, 595.
Malformations. A case of multiple malformations, 94; a case of congenital malformation of the genital organs, Cummings, E. F., 195, 201; remarkable case of defective development, Atkinson, 310.
Malpractice. A flimsy suit for malpractice, 305; a malpractice suit against an estate, 383.
Malley Trial. A review of the evidence in the Malley trial, Harris, F. A., 361, 370.
Marcy, H. O. Some forms of disease of the placenta, 105; surgical treatment of intestinal obstruction, 584; the restoration of the perinæum by a new method, 613.
Marshall, J. Pyrrhea alveolaris, 615.
Marshall, J. S. Denudation or erosion of the teeth, 615.
Martin, H. A. Vaccine virus, 256; vaccination during pregnancy, 257; vaccination and propagation of vaccine virus, 586.
Mason, A. L. A case of poisoning with illuminating gas, 196, 203.
Massachusetts law to prevent the adulteration of food and drugs, 475.

Master's Degree. Subjects for master's degree at Harvard, 1655-1791, 137.

Mastitis. Treatment of puerperal mastitis by iodide of lead ointment, Gaunt, T. T., 70.

Materia Medica and Therapeutics. U. S. Pharmacopœia, 38; eucalyptus trees at Rome, 69; treatment of puerperal mastitis by iodide of lead ointment, Gaunt, T. T., 70; medical treatment of insanity, with special reference to opium, Channing, W., 86; the new pharmacopœia, Davenport, B. F., 104; the differential indications for the use of dynamic and franklinic or static electricity, Rockwell, A. D. 108; Franklinism, or atmospheric electricity as a remedy, Garratt, A. C., 123; ergot and ruptured uterus, Buckingham, E. M., 125; on hydrotherapeutics, Dujardin-Beaumetz, 169; hydriatry, 186; diet in the treatment of the gouty dyscrasia, Draper, W. H., 205; experiments upon rabbits with convallaria majalis, 214; the action of quinine upon the ear, Green, J. Orne, 220, 226; report in materia medica and pharmacy, Bolles, W. P., 250; the use of the iron salts, James, P., 283; New Mexico, its climatic advantages for consumptives, Tyndale, J. H., 265, 313; prescription of ready-made identical specialties, 327; poisoning by apomorphia, Pécholier, 333; on medical electricity, Dujardin-Beaumetz, 337; explanatory remarks upon neuro-dynamic medicine, with cases, Kinnear, B. O., 366, 370; a clinical study of caffeine and convallaria majalis as cardiac tonics, Robinson, B., 373; inguvin, Ellis, F. W., 381; note upon crystallized sisterin, Griswold, G., 398; the superior value of bromide of sodium, Field, H. M. 438; venesection versus bromide in eclampsia, Bowditch, H. I., 471; the Massachusetts law to prevent the adulteration of food and drugs, 475; the destruction of nasal polypi by chromic acid, Donaldson, F., 517; the medicines of to-day, Bolles, W. P., 535; the use of antiseptics after abortions and labor, Wylie, W. G., 563; comparison of antiseptic and non-antiseptic methods of treatment, Allen, D. P., 582.

Maughs, G. M. Midwifery and gynæcology of the ancients, 613.

McBride, P. The functions of the semicircular canals, 550.

McCollom, J. H. A typhoid patient arrested for supposed drunkenness, 274.

Measles. Earache in measles, Theobald, S., 310; the notification of measles, 547.

Meigs, A. V. Artificial feeding for infants, 118.

Membrane from intestine, Goss, F. W., 35.

Milk. Undiluted milk for infants, 526.

Mills, C. K. The duty of medical colleges and the general practitioners towards mental and nervous diseases, 132; arsenical paralysis, 248, 269; a case of locomotor ataxia terminating as general paralysis of the insane, 622.

Miller, H. G. Simulated amaurosis, tumors of the orbit, impairment of the retina by exposure to the sun's rays, 293.

Mind. Governor Butler's lunacy commissioner, 65; notes on a case of acute chorea in an adult, associated with profound mental disturbance, Stedman, H. R., 76, 86; medical treatment of insanity, with special reference to opium, Channing, W., 86; functions of a medical staff of an insane hospital, Green, T., 132; the duty of medical colleges and the general practitioners towards mental and nervous diseases, Mills, C. K., 132; how to protect the insane, Parrish, J., 132; the legal rights of the insane and their enforcement, Bell, C., 133; the weight and development of the brain as indicative of intellectual force, 184; what may reasonably be expected from more instruction in mental diseases, 235; poor-house treatment for lunatics, 279; recent progress in mental disease, Goldsmith, W. B., 345, 369; female hallucinations, 358; the "images" suit, 377; a form of loss of memory occasionally following cranial injuries, Bell, J., 382; the care of insane criminals, 425; insanity as a defense for crime, Corkhill, G. B., 447; discharged lunatics, 474; hereditary syphilis and idiocy or juvenile dementia, 498; change in the form of insanity during acute attacks, occurring in young persons, Stedman, H. R., 505, 513.

Minot, C. S. The fœtal envelopes, 409; report on general physiology, 440; retrogressive history of the fœtus, 529.

Moore, E. M. Treatment of old cases of compound dislocation of the ulna in conjunction with Colles' fracture, 585.

Morgan, E. C. A case of enormous tumor removed from the glosso-epiglottic sinus, with remarks, 522.

Morgan, J. H. Aneurism of the descending aorta, 16.

Morris, J. What means can be judiciously used to shorten the term and lessen the hours of labor, 613.

Morse, E. S. Address at annual dinner of Massachusetts Medical Society, 592.

Morton, W. J. Neuritis following dislocation at the shoulder, 522.

Mundé, P. F. Secondary puerperal hæmorrhage, 111.

Murray, K. D. Yellow fever, 585.

Musser, J. H. Two cases of carcinoma of the stomach, 61; ulcer of the stomach in the anterior wall, adhesions to the abdominal wall, hæmorrhages and pain, death from morphia habit, 111.

Nanecrede (Philadelphia). A tumor composed of miliary tubercles of the subcutaneous adipose tissue connected with one of the anterior cutaneous branches of the lumbar nerves, 324.

Nash, H. M. The yellow fever plague fly; Bright's disease, 303.

National Board of Health, 107.

Nephrotomy for hydronephrosis, recovery, Cabot, A. T., 173, 182.

Nervous System. Sunstroke, Shattuck, G. B., 10; writer's cramp, 46; allochiria, its nature and seat, Hammond, W. A., 58; a case of paralytic dislocation of the hip-joint, and other cases of infantile paralysis, with remarks on the surgical treatment of infantile paralysis, Bradford, E. H., 73, 86; notes on a case of acute chorea in an adult, associated with profound mental disturbance, Stedman, H. R., 76, 86; two cases of sunstroke, Sumner, A. M., 180; ocular symptoms as localizing symptoms, Webber, S. G., 217, 226, 244; arsenical paralysis, Mills, C. K., 248; nervous cough, Bowditch, H. I., 297; catarrhal headaches and allied affections, Brandeis, R. C., 324; the treatment of delirium tremens, Ayer, J. B., 326; explanatory remarks upon neuro-dynamic medicine, with cases, Kinnear, B. O., 366, 370; embolism of the left middle cerebral artery accompanied by aphasia and agraphia, Lyman, G. H., 371, 388; case of glioma of the pons varolii, Putnam, J. J., 437; a case of obscure nervous fatal disease, Shattuck, F. C., 460, 469; the true significance of some of the prominent symptoms in so-called spinal concussion, Putnam, J. J., 491; tympanic caries producing sub-dural abscess opening into lateral sinus, 514; chorea laryngis, Knight, F. I., 517; paresis of the constrictor muscles of the pharynx simulating spasmodic stricture of the œsophagus, Bosworth, F. H., 518; laryngeal paralysis from aneurism, Porter, W., 519; reflex phenomena due to nasal disease, Elsberg, L., 519; neuritis following dislocation at the shoulder, Morton, W. J., 622; lead-poisoning simulating other forms of disease, Putnam, J. J., 622; a case of general neuralgia, Eskridge, J. T., 622; a case of locomotor ataxia terminating as general paralysis of the insane, Mills, C. K., 622.

New England. Consumption in New England, Hurd, E. P., 292, 316, 481.

New Hampshire. Regulation of the practice of medicine in Illinois and New Hampshire, 523.

New Jersey. Sanitary and medical legislation in New Jersey, 448.

New Mexico, its climatic advantages for consumptives, Tyndale, J. H., 265, 313.

Newport. Concerning Newport, R. I., as a resort for consumptives, Tyndale, J. H., 188, 331, 462; Storer, H. R., 232, 404.

Newton, Heber. The obligations of society to the insane, 594.

New York. The new Code of Ethics, Sayre, L. A., 107; an Italian hospital in New York, 138; the meeting of the New York State Medical Society and its Code of Ethics, 161; the water supply of New York, 163; New York State Board of Health; rulings as to mixtures, 163; the New York Code, 211; apartment houses in New York, 290; the water supply of New York City, 304, 448; election of delegates in favor of the old Code of Ethics to the New York State Medical Society, 328; an open letter (Code of Ethics), 381; none but those in favor of the National Code of Ethics to be elected Fellows of the Academy in future, 398; New York letter, 549.

Nitrite of Amyl, poisoning from, 526.

Norway. Hawaiian and Norwegian leprosy, 353.

Noyes, R. F. Perityphlitis, 17.

Ocular Symptoms as localizing symptoms, Webber, S. G., 217, 226, 244.

Obstetrics. Report of a summer course in obstetrics, Green, C. M., 434.

Oglesby. Disease of the optic disk following typhoid fever, 476.

Ohio. School hygiene, provision therefor in Ohio, 304.

Oil. How they make "cod oil" at Swampscott, 233.

Old Age. Death in old age from cardiac syncope, with lesion of bowels presenting symptoms of inflammation, 38.

Opium. Medical treatment of insanity, with special reference to opium, Channing, W., 86.

Orchitis. Carcinoma following orchitis, Fuller, F. B., 16.

Orthopraxy. Double osteotomy and osteoclasis, Bradford, E. H., 24; report on surgery of the joints and of deformities, Bradford, E. H., 392; cases of rheumatic curvature of the spine, Bradford, E. H., 445; amputation below the knee-joint in preference to "Brisement forcé" or resection in certain cases of deformity with anchylosis, Sayre, L. H., 584.

Osgood, H. Misleading cardiac murmurs and expiratory auscultation of the heart, 289, 296; old abscess discharging through the urethra, 491.

Ostitis and arthritis, Ifield, W. C. B., 155.

Otis, W. J. New instrument for the operation of tracheotomy, 348, 396; case of sloughing of the mucous membrane of the bladder from cystitis following confinement, 458, 468.

Ovarian Cysts, Blodgett, A. N., 204.

Overwork. On overwork and strain of the heart, Germain-Sée, 1.

Otology. Recent progress in otology, Green, J. O., 681.

Paget. Sir James Paget on some rare and new diseases, 66; Paget's disease of the nipple, 94.

Palmer, W. H. The office and duty of coroners, 16.

Pancreas. Small tumor of the head of the pancreas, Bruen, E. T., 110.

Paralysis. A case of paralytic dislocation of the hip-joint, and other cases of infantile paralysis, with remarks on the surgical treatment of infantile paralysis, Bradford, E. H., 73, 86; arsenical paralysis, Mills, C. K., 248, 269.

Parasites. Autogenesis of cysticerci, 70.

Parker, W. T. A new tongue depressor, 444.

Paris. Waifs of Paris, 550.

Parrish, J. How to protect the insane, 132.

Parrish, W. H. Enlarged lymphatic glands, 88; polypi from the uterine cavity, 88.

Pasteur. Dr. Robert Koch's latest estimate of Pasteur's methods and discoveries and of the present position of the general inoculation problem, 64; Pasteur's reply to Koch, 209.

Pathology. A case of mitral obstruction with sequential lesions, Bruen, E. P., 14; recent progress in pathology and pathological anatomy, Whitney, W. F., 463, 488; specimens of tumors and dissected nerves, 277.

Pécholier. Poisoning by apomorphia, 333.

Peltzer Trial, 141.

Pennsylvania. Medical legislation in Pennsylvania, 253.

Perinæum. Wound of perinæum extending into vagina, 344, 347.

Peritonitis. Acute infantile peritonitis, Rotch, T. M., 268, 274.

Perityphlitis, Noyes, R. F., 17.

Peters, J. C. The National Board of Health, 107.

Pharmacopœia. United States Pharmacopœia, 38; the new Pharmacopœia, Davenport, B. F., 104.

Philadelphia water supply, 115; annual reports of the Standing Committees of the College of Physicians of Philadelphia, 117.

Phthisis. The morphology of pulmonary phthisis, Bruen, E. P., 228; the bacillus tuberculosis and the contagiousness of phthisis, 235.

Physiology. Force production, Bowditch, H. P., 285; the fœtal envelopes, Minot, C. S., 409; report on general physiology, Minot, C. S., 440; the study of physiology in a veterinary school, 453; activity of the senses in new-born infants, 454; smell, hygienically and medico-legally considered, Wagner, C., 520; experimental researches on the tension of the vocal bands, Hooper, F. H., 521.

Placenta. Some forms of disease of the placenta, Marcy, H. O., 105.

Plastic Operation for a burn of the arm, Porter, C. B., 469.

Pleurisy. Notes on a case of pleurisy with an unusual amount of effusion, Darling, A. E., 443.

Plumbing. Regulation of plumbing in the city of Boston, 46, 114; the siphoning of sewer traps, Bowditch, E. W., 155; the proper and faulty methods of plumbing, drainage, and ventilation, 596.

Plumbing Appliances. Clark, T. M., 586.

Pneumonia, Keene, S. S., 298.

Poisons. A case of poisoning with illuminating gas, Mason, A. L., 196, 203; arsenical paralysis, Mills, C. K., 248, 269; transfusion in gas-poisoning, Garrigues, H. J., 310; poisoning by apomorphia, Pécholier, 333; a case of obscure and rapidly fatal disease attended by extensive painful tumefactions of the skin, Greene, J. S., 462; poisoning from nitrite of amyl, 526.

Polypi from the uterine cavity, Parrish, W. H., 88; on the results of treatment of naso-pharyngeal polypi, Stebbins, R. P., 520; the destruction

of nasal polypi by chromic acid, Donaldson, F., 517; post-partum polypoid tumors, Landis, W. H., 613.

Poor-House treatment for lunatics, 279.

Porro's Operation. Gastro-elytrotomy (Thomas's operation) compared with oöphoro-hysterectomy (Porro's operation), Garrigues, H. J., 13.

Porter, C. B. Case of plastic operation for a burn of the arm, 469.

Porter, W. Laryngeal paralysis from aneurism, 519.

Prague. Notes on the lying-in hospitals of Vienna, Dresden, and Prague, Lombard, F. H., 505.

Pregnancy, Affections connected with. On sudden death by the entrance of air into the uterine veins, Draper, F. W., 3, 28; progress in obstetrics, Richardson, W. L., 31; treatment of puerperal mastitis by iodide of lead ointment, Gaunt, T. T., 70; affections connected with the obliteration of the uterine cavity in pregnancy, Storer, H. R., 105; some forms of disease of the placenta, Marcy, H. O., 105; secondary puerperal hæmorrhage, Munde, P. F., 111; a case of tubal pregnancy, Gannett, 155; affections connected with septicæmia in women, Brown, W. S., 254; spontaneous separation of the funis, Burge, W. J., 299; cases of laceration of the cervix uteri occurring in the New England Hospital for the two years beginning October 1, 1880, Smith, M. A., 322; affections connected with rupture of the bladder from abortion, 334; basilysis, Simpson, 357; labor complicated by vaginal occlusion, 358; emphysema occurring during labor, Dunn, W. A., 397; report of a summer course in obstetrics, Green, C. M., 434; affections connected with venesection versus bromides in eclampsia, Bowditch, H. I., 471; puerperal fever, prophylaxis in hospital practice, notes on the lying-in hospitals of Vienna, Dresden, and Prague, Lombard, F. H., 505; the use of antiseptics after abortions and labor, Wylie, W. G., 563; affections connected with delivery of the after-coming head by the occiput, Seymour, W. W., 598; the restoration of the perinæum by a new method, Marcy, H. O., 613; what means can be judiciously used to shorten the term and lessen the hours of labor, Morris, J., 613; midwifery and gynæcology of the ancients, Maughs, G. M., 613.

Prince, M. The typhoid epidemics of the last decade and the necessity of compulsory disinfection, 153, 175, 193.

Prizes. A prize on the prevention of blindness, 48; the Hammond prize of the American Neurological Association, 192; the causes and prevention of the pollution of streams, the king of Saxony's prize, 355; Warren triennial prize, 499.

Prostitution. The regulation and repression of prostitution, Sturgis, F. R., 289.

Providence. Sanitary statistics regarding the recent epidemic of typhoid fever in Providence, Swarts, G. T., 298.

Puerperal Affections. Puerperal hæmorrhage, Munde, P. F., 111; puerperal septicæmia, Bryant, W. N., 411.

Putnam, J. J. Case of glioma of the pons varolii, 437; the true significance of some of the prominent symptoms in so-called spinal concussion, 491; lead-poisoning simulating other forms of disease, 622.

Putnam-Jacobi, M. Opening lecture on diseases of children at the Post-Graduate Medical School, New York, 121, 145.

Pyrrhea Alveolaris. Marshall, J., 615; amaurosis dependent on dental irritation, Allport, W. W., 615.

Quinine. The action of quinine upon the ear, Green, J. Orne, 220, 226.

Radius. Report of resection of the radius in 1828, Hopkins, W. B., 436.

Railroad Employees. Defective vision among railroad employees, attempt to prevent examinations, 209.

Rare and new diseases, Paget, J., 66.

Recent Progress. Surgery, Beach, H. H. A., obstetrics, Richardson, W. L., 31; gynæcology, Davenport, F. H., 54; diseases of children, Rotch, T. M., 80, 127; forensic medicine, Draper, F. W., 149; medical chemistry, Hills, W. B., 177; thoracic diseases, Knight, F. I., 197, 223; theory and practice of medicine, Shattuck, G. B., 272, 293; anatomy, Dwight, T., 319; mental disease, Goldsmith, W. B., 345, 369; surgery of the joints and of deformities, Bradford, E. H., 392; skin, Tilden, G. H., 415; physiology, Minot, C. S., 440; pathology and pathological anatomy, Whitney, W. F., 463, 488; dentistry, Rollins, W. H., 511; ophthalmology, Wadsworth, O. F., 532; otology, Green, J. Orne, 581; surgery, Cabot, A. T., 610.

Resection. Report of a case of resection of the radius made by Dr. J. R. Barton in 1828, Hopkins, W. B., 436.

Respiratory System. Secondary laryngeal lupoid degeneration, Bowen, W. S., 17; stenosis of the larynx, Hooper, 36; cancer of the left kidney and lung, Goss, F. W., 57; croupous inflammation of the pharynx, larynx, and trachea, with occlusion of the larger bronchi, Draper, F. W., 204; the morphology of pulmonary phthisis, Brown, E. P., 228; resection of the lung as proposed by Dr. Bloch, 261; consumption in New England, Hurd, E. P., 292, 316; nervous cough, Bowditch, H. I., 297; pneumonia, Keene, S. S., 298; case of metastatic pneumonia following pistol-shot wound of the temporal bone, Fisher, H. M., 349; notes on a case of pleurisy, with an unusual amount of effusion, Darling, A. E., 443; a case of caries of the ribs, with abscess of the chest, Sabine, G. K., 457, 467; rapid conversion of a serous into a purulent pleuritic effusion, evacuation through the lung, pneumo-pyo-thorax; recovery, Shattuck, F. C., 461, 470; a case of pleurisy, Blanchard, B. S., 501; specimens (lungs, heart, and kidneys) from a case of Bright's disease, Henry, F. P., 515; myxomatous tumor of the subcutaneous cellular tissue of the chest, MacConnell, 516; new facts in laryngotomy, Lefferts, G. M., 516; a common form of vocal disability resulting from pathological processes, the phenomena used to demonstrate falsity of one system of voice training, Langmaid, S. W., 516; the destruction of nasal polypi by chromic acid, Donaldson, F., 517; chorea laryngis, Knight, F. I., 517; the treatment of laryngeal phthisis, Ingalls, E. F., 517; the healing of ulcers in laryngeal phthisis, Jarvis, W. C., 518; paresis of the constrictor muscles of the pharynx simulating œsophagic stricture of the œsophagus, Bosworth, F. H., 518; photographing the larynx, French, T. R., 518; congenital tumors of the larynx, Johnson, H. A., 518; laryngeal paralysis from aneurism, Porter, W., 519; reflex phenomena due to nasal disease, Elsberg, L., 519; smell, hygienically and medico-legally considered, Wagner, C., 520; asymmetry of the nasal chambers, Allen, H., 520; on the result of treatment of naso-pharyngeal polypi, Stebbins, R. P., 520; a case of thyrotomy for morbid growth, with subsequent development of epithelioma in the cutaneous cicatrix, but without involvement of the interior of the larynx, Solis-Cohen, J., 521; experimental researches on the tension of the vocal bands, Hooper, F. H., 521; aural complications of inflammatory conditions of the nose and throat, Robinson, B., 522; the lacunæ tonsillaris, Delavan, D. B., 522; the value of post-pharyngeal papillomata as a means of diagnosis in tubercular disease, Major, G. W., 522; a case of enormous tumor removed from the glosso-epiglottic sinus, Morgan, E. C., 522; a case of sudden death occurring after tracheotomy, Asch, M. J., 522; adhesion of the velum to the walls of the pharynx, Smith, A. H., 522; lympho-sarcoma of the lung, Knight, F. I., 535; a case of empyema, Richardson, M. H., 555, 562; alimentary canal in bronchitis and phthisis, Reynolds, T. N., 585; elements of prognosis and therapeutics of laryngeal tuberculosis, Solis-Cohen, J., 586; appearance of the mucous membrane of the throat and nose in adult patients, Rumbold, 617.

Lectures.

ON OVERWORK AND STRAIN OF THE HEART.[1]

BY PROFESSOR GERMAIN-SÉE.

Member of the Academy of Medicine, Member of the Faculty of Medicine, Paris, France.

Gentlemen, — I shall treat in this lecture of an asthenic functional malady of the heart resulting from overwork of that organ, and known as heart strain, or acute asystolism.

CAUSES OF HEART DISEASE OTHER THAN VALVULAR LESIONS.

The labors of Laennec and Bouillaud directed somewhat too exclusively the attention of physicians to the valvular lesions of the heart, and their stethoscopic signs; as a result, one entire side of cardiac pathology, whose importance cannot be denied, has been too much neglected. Do not understand me as disparaging the immense services rendered by auscultation, or the importance of the doctrine of valvular endocarditis in the study of diseases of the heart. But I do insist that you shall rightly understand that the valvular lesion is after all only a menace, that it has no gravity except in relation to its possible consequences, and that these consequences may result from other causes just as surely and as fatally. "We often meet," says Beau in his Treatise on Auscultation, "diseases of the heart characterized by rational symptoms the most positive, and whose gravity augments to the end, and the autopsy discloses no lesions which sufficiently explain the observed symptoms and the death." We know at the present day that we need not limit our search for those lesions to the heart itself, and that if the diseased heart acts injuriously on the organs to which it sends blood, the primitive morbid alteration of those peripheral organs may have a no less disastrous influence on the centre of circulation; that, in a word, asystolism — a condition in which the heart is overcome — may be the consequence of a pulmonary, hepatic, renal lesion, as well as of a valvular lesion. This is not all; apart from all these peripheral causes, the cardiac malady may be definitely constituted as a temporary or permanent affection by the simple fact of an excess of work of the muscle, — by exhaustion of the myocardium. Here, then, are pathological states which deserve to be pointed out to you, and which should be studied along with the anomalous forms of heart diseases.

INFLUENCE OF PULMONARY LESIONS.

The sympathy which exists between the lungs and the heart did not escape the ancient authors. "Every cause," says Kreysig, "which troubles the respiration, whether it consist in a mechanical impediment outside, or in a disease within the respiratory organs, must necessarily disturb the healthy action of the heart, not only by modifications effected in the influx and efflux of blood, but also by changes in the chemical constitution of this fluid, or in both ways at the same time." And further on he adds that diseases of the lungs have an influence perhaps greater on the heart and pulse than diseases of the heart itself. This proposition will not probably be deemed an exaggeration, if it be remembered that the greater part of chronic affections of the lungs — phthisis pulmonalis excepted — give rise to symptoms of the forced heart, and often terminate in asystolism. This is what you will observe in chronic pulmonary emphysema, chronic bronchitis, and dilatation of the bronchi.

INFLUENCE OF PLEURAL LESIONS.

The influence of lesions of the pleura is less understood. Sénac remarked that pleurisies augment the volume of the heart. "I have often observed," says he, "that the right auricle and ventricle undergo considerable hypertrophy after such diseases." You can readily understand how extensive pleuritic adhesions, by hindering the expansion of the lung, and, consequently, the free distribution of the blood by the pulmonary artery, may after a while induce cardiac dilatation, and act in the same way as sclerosis of the pulmonary tissue itself.

INFLUENCE OF RENAL AFFECTIONS.

That there is a marked relationship between lesions of the left heart and renal affections, and especially interstitial nephritis, has been proved by Bright, and subsequently by Traube. This relationship explains a certain number of cardiac troubles, in which all signs of valvular lesion are absent. These are sometimes phenomena of cardiac erethism, sometimes symptoms of asthenia and exhaustion.

You will hear patients complain of shortness of breath, of being oppressed after the least exertion, of having a continual sensation of weight in the precordial region, of the occurrence of sudden violent attacks of palpitation; the pulse is sharp and vibrating, the heart voluminous, the shock of the apex very low down and very strong. You would naturally suspect the existence of some disease of the orifices and the cavities, and yet auscultation reveals no abnormal bruit either at the base or apex. Under these circumstances you ought to inquire if you have not here to do with cardiopathy of renal origin, and the existence of polyuria (especially in the night time), the presence of a light opalescent cloud of albumen in the urine, the detection at a given moment of the sign indicated by Sibson and Potain, the *bruit de galop*,[2] will help you to a correct diagnosis.

In other circumstances it is to the congeries of symptoms known under the name of *the forced heart* (cœur forcé) that the renal lesion gives rise. I have alluded to this subject in my lectures on cardiac dyspnœa,[3] and shall not repeat what I then said. These cases are always hard to diagnosticate, and to know whether you have to deal with a primitive or a secondary affection of the heart is often impossible.

INFLUENCE OF HEPATIC DISEASE.

The same symptoms of forced heart, whose anatomical expression consists in dilatation of the cardiac chambers, are observed also as a consequence of disease of the liver. Stokes in his remarkable work has clearly indicated this fact: "When there is com-

[1] Delivered in La Charité and translated, with permission of the author, by E. P. Hurd, M. D., Newburyport, Mass.

[2] [A reduplication of the systolic sound of the heart (sometimes heard even when the heart is healthy). Potain, in cases of hypertrophy of the heart from renal degeneration, has met with and described a variety of double first sound in which, besides the two normal sounds, a third was heard coming immediately before the first sound, and separated from it by a short pause. This presystolic sound is supposed to be due to contraction of the hypertrophied auricles and increased tension of the auriculo-ventricular valves. — Trans.]

[3] Germain-Sée, "Maladies du Cœur et en particulier de leur Formes Anomales." O. Dorn, Paris, 1883, Chap. II.

plication of an hepatic affection, mercury acts with singular efficacy. This is not easy to explain. You are often ignorant whether the disease originated in the liver or in the heart. It is certain that when these affections are combined the two diseased organs react mutually on each other; whatever perturbs the one determines in the other new troubles." [1]

In the observation of Professor Colles, of Dublin, which Stokes relates with minute details, the autopsy disclosed extreme dilatation of the cavities of the heart without any valvular lesion. The liver, without any excessive increase in volume, extended below the border of the false ribs, was of deep mahogany color, was intensely congested and tumefied, and its surface was rough and granular. The dilated veins let escape a large quantity of dark blood. The gall-bladder contained thirty biliary calculi of moderate size.

It is to such facts as these that Professor Potain has recently called attention. Gangolphe and Fabre had described, as accompaniments of jaundice, certain cardiac troubles which they ascribed to the action of biliary salts — retained in the blood — on the fibre of the myocardium. In the cases observed by these writers there was a slight increase of the precordial dullness, a systolic souffle at the apex, and often exaggeration of the second sound a little above the nipple. Potain thinks that these cardiac troubles may arise as a temporary disorder in acute affections of the liver, or as a permanent disorder in chronic affections of that organ and become the origin of a veritable organic lesion of the heart. The right auricle and ventricle naturally first suffer dilatation, and this makes itself manifest by an increase of the transverse dullness, and by a *bruit de galop* having its seat along the right border of the sternum, and which Potain calls *bruit de galop* right, to distinguish it from the *bruit de galop* of the left side of the heart, which occurs in interstitial nephritis. The judicious physician of the Hôpital Necker does not, moreover, attribute directly to the liver a mechanical action on the right heart. In his opinion the hepatic lesion acts by irritation of the medulla oblongata through sensory branches of the *par vagum* going to the liver; the irritation is reflected from the medulla upon the pulmonary circulation, causing augmentation of pressure in the blood-vessels, and this results in dilatation of the cavities of the right side of the heart.

INFLUENCE OF GASTRIC AND INTESTINAL DISORDERS.

It is not alone in affections of the liver that this dilatation is seen; diseases of the stomach and intestine may give origin to similar troubles. It is well known that a great many dyspeptics suffer from palpitations, and have an intermittent and slow pulse. Enteritis and diarrhœa affect the heart similarly. Out of two hundred cases of irritable heart reported by Da Costa [2] during the war of the American Rebellion, sixty-one were due to intestinal derangement. M. Tessier, of Lyons, has reported a number of cases of the same kind. M. Potain has noted, as a phenomenon of the same order, a temporary dilatation of the right heart, which he explains by the same reflex mechanism as the dilatation of hepatic origin.[3] Can this temporary dilatation eventuate, in the long run, in true asystolism? There is nothing at the present time which justifies a positive affirmation on this subject.

It is apparent from what has now been said that in the absence of valvular lesions to account for certain cardiac troubles attended with dilatation, we may find in certain lesions of peripheral organs an adequate cause. I am not now going to speak of other alterations, whether of the myocardium, the pericardium, or the aorta, which are competent to produce the same effects, and this without the presence of any murmur appreciable to auscultation.

PRIMITIVE DILATATION AS A RESULT OF OVERTAXING THE HEART.

Does there exist, independently of these known causes, a dilatation, *quasi* spontaneous, of the heart, eventuating under the influence of over-exertion of the myocardium? Is it possible that this primitive dilatation may determine hypertrophy, and, in time, all the signs and all the consequences of valvular lesions? Such is the new problem presented to our consideration by the observations and the monographs published during the last ten or twelve years in England, in America, and in Germany.

Peacock, from observations of Cornish miners, was the first to point out the existence of dilatation and hypertrophy of the heart, uncomplicated or co-existing with mitral incompetency, and undergoing development in a great number of workingmen.[4] It was impossible to attribute these lesions to any other cause than exhaustion by excessive and prolonged toil. In his opinion these cardiac alterations were the result of overtaxing the heart. Several years later Clifford Allbutt, from an experience similar to that of Peacock, among a heavily laboring population of miners, forgemen, porters, etc., confirmed Peacock's observations. In individuals still young, who had never been exposed to any of the habitual causes of heart disease, he witnessed the development, first of all, of trifling cardiac ailments, such as palpitations and shortness of breath;

[1] Stokes, Treatise on Diseases of the Aorta.

[2] [Da Costa, Irritable Heart. (American Journal Medical Sciences, 1871, page 17.)

Lecorché (Études Medicales, Paris, 1882, page 440) makes some very judicious remarks *à propos* of this form of cardiac disorder, for which Da Costa's name, "irritable heart," is not a bad one. He says "it is possible that forced marches, excessive fatigue, etc., may produce temporary cardiac troubles in debilitated subjects, troubles which one may properly refer to a transient dilatation of the heart, but it is not shown that in absence of all lesion of the myocardium, these disorders may end in a permanent cardiac affection. If, on the contrary, the cardiac muscle is enfeebled as a result of some alteration in the quality of the blood or disease of its nutrient arteries, you may see supervene, generally in subjects of a certain age, as consequence of fatigue, excessive work, excess of coitus, violent emotion, a mild attack of bronchitis, etc., all the symptoms of asystolism without any valvular lesion.

In questions of ætiology, Lecorché remarks further on, the complexity of causes hardly ever permits from an impartial observer an absolute solution.

He reports two interesting cases. The first patient had been of intemperate habits. He entered the Hôpital Dubois for severe functional (?) heart troubles: shortness of breath, palpitations, thoracic oppression, and cough. There was a rapid increase of dyspnœa, and anasarca of the lower extremities supervened; there was also some pulmonary œdema, but no ascites. The asystolism became of a most marked character; complete arythmia. There was some increase of dullness transversely. No murmur. The patient died in a coma. Although Lecorché regards this as a case of "forced heart," resulting from painful emotion (grief from family losses), it seems probable that an autopsy would have revealed valvular lesion, and had the patient come earlier under observation a murmur would doubtless have been heard.

Case II. is described as a cardiac affection of nervous origin; "forced heart," without valvular lesion, consequent on violent anger. The symptoms resemble those of the previous case, though the dyspnœa was more paroxysmal; there was no œdema; asystolism was very marked. One feature of this case was the occurrence of frequent syncopal attacks. This patient, like the former, had been a hard drinker, and there was evidently atheromatous and fatty degeneration.]

[3] See in this connection the thesis of his pupil, Destreaux, Dilatation of the Heart, of Gastric Origin. (These de doctorat, Paris, 1879.)

[4] [Vide Croonian Lectures, Lancet, 1865. TRANS.]

then, coincidently with repetition and aggravation of these symptoms, he noted a slight increase of precordial dullness, due to commencing dilatation; finally the dilatation became more marked, and was accompanied with compensating hypertrophy. Clifford Allbutt, like Peacock, referring these cardiac troubles to the habitual conditions of life of these patients, did not hesitate to attribute the cardiac dilatation to a veritable exhaustion of the myocardium, which, by virtue of over-exertion, had become incapable of performing its ordinary tasks.

Similar facts have been observed by Thurn and Fraenzel in the German army, by Myers in the English army,[1] by Da Costa in the American army. All these writers are agreed that an acute dilatation of the heart, resembling by functional and physical signs a valvular affection in its first stages, may manifest itself suddenly, especially in young soldiers, as a result of overwork and forced marches.

Seitz, pupil of Professor Bienner, in his thesis on the effects of overwork of the heart, has described the same group of morbid phenomena; his description (which I need not here reproduce) is trait for trait the remarkable tableau, painted by Beau, of asystolism. The only apparent difference is furnished by the necropsy, which discloses the absence of all lesion of the endocardium, pericardium, aorta, and other organs capable of explaining these cardiac phenomena. And yet Beau did not fail (as I have before remarked) to indicate such cases of asystolism where the lesions found at the autopsy are insufficient to explain the symptoms observed and the fatal termination.

There is, then, really nothing new in these facts except the interpretation which writers who have noted them have given, and the consequences which they have deduced from them. These writers have not been content to attribute these asystolic troubles to exaggerated fatigue of the heart. They have made them act a pathological part in the development of certain valvular affections. The cardiac dilatation produced by exhaustion of the myocardium is followed by hypertrophy, then by a series of lesions pertaining to the aorta and the orifices of the heart. This is the way in which Clifford Allbutt demonstrates the order in which the chronic morbid changes present themselves: —

(1.) Dilatation of the right heart. (2.) Dilatation of the left heart. (3.) Hypertrophy of the left vent tricle or of both ventricles. (4.) Chronic inflammation of the aorta and aortic valves. (5.) Dilatation of the aorta. (6.) Incompetence of the aortic valves. (7.) Compensatory hypertrophy of the left ventricle. (8.) Loss of compensatory hypertrophy, and dilatation of the left ventricle. (9.) Consequent mitral regurgitation.

I do not refuse to admit that a sudden and transient dilatation of the right heart may be the effect, in an overworked individual, of an abrupt augmentation of blood pressure in the venous system; I do not dispute the facts observed by Kreisig, Maurice Raynaud, Thurn, Myers, and Da Costa. Clifford Allbutt cites further, as an example of this kind of suddenly forced heart, the following fact which he observed in his own person during a journey in Switzerland: After several days of fatigue, in which he was climbing mountains difficult of ascent, he was seized with a strange shortness of breath accompanied by a very painful sensation of oppression and beating in the epigastric region, and percussion revealed an increase of precordial dullness. These troubles, as well as the increase of dullness, disappeared after a season of repose, but returned as soon as he again undertook to climb the mountains. In the night time he was awakened by an intense dyspnœa and by painful palpitations; the precordial dullness was greater than it was before; full inspirations from the open window calmed this oppression. I believe, with the English author, that these troubles were due to sudden distention of the fatigued right ventricle. But it is difficult for me to admit that without any previous material lesion of the myocardium this dilatation may become, by the sole fact of exhaustion of the cardiac muscle, the origin of organic lesions of the heart. It must not be forgotten that if the miners and laboring men of Peacock and Allbutt were subjected to arduous and prostrating toil, they were also, by that very fact, predisposed to seek in alcoholic stimulants (in which, in all likelihood, many of them freely indulged) a solace for the fatigue and misery of their condition. I attribute, then, to alcoholism, of which it does not seem that those writers made sufficient account, an undeniable action on the nutrition of the cardiac muscle, and this would explain the valvular lesions of many of the cases which they have noted. That, under these conditions, the muscle of the heart, altered by alcohol, should give way amid the general prostration of the vital powers is not at all astonishing, but the mechanism of this dilatation does not appear to me to differ essentially from that which we observe in dilatations by any cardiac lesion whatever, and it seems useless to me to make of this variety of asystolism a separate disease.

TREATMENT.

It is not in our power to lay down any precise rules of treatment of a malady whose nature we are just beginning to investigate and understand. First and foremost, repose and the proper diet to promote recuperation are indicated; the rest is uncertain.

ON SUDDEN DEATH BY THE ENTRANCE OF AIR INTO THE UTERINE VEINS.[2]

BY F. W. DRAPER, M. D.

The practice of obstetrics is acquainted with many special risks to the two lives which depend on its gracious service; but it knows of no incident of the lying-in room so deplorable as the sudden death of the woman recently delivered. In the whole range of midwifery experience hardly anything so appalling can happen. Ordinary emergencies, like hæmorrhage, eclampsia, and placenta prævia, are not without some premonitory hint or warning to convey to the alert attendant the message which may suggest or guide his action. But here, death overwhelms the victim when all seems serene and without token of catastrophe. The woman has passed her travail, her fears have been supplanted by happy fruition, her delivery is complete in more than the obstetric sense, and she looks forward to a future full of hope. In a second all is changed; almost before she can define her feelings of distress and dread, or summon help, the woman is dead. In whatever manner the change comes, whether it be by

[2] Read before the Obsterical Society of Boston, December 9, 1882.

syncope, or by pulmonary or cardiac thrombosis, or by the mischief of a wandering clot, or by the admission of air to the circulation, the stroke is fearful in its unheralded suddenness and its quick fatality.

But that which carries consternation and grief under the ordinary conditions of the lying-in chamber becomes sometimes a fortunate medico-legal accident. A woman seeks the aid of an abortionist to assist her in destroying the life of the child within her womb. She narcotizes her conscience by specious falsities, so that, to her, the act of killing in which she engages with her accomplice does not carry with it any quality of crime, and she readily takes whatever physical risks pertain to the wretched business. If, then, in consequence of the abortionist's manipulations, death suddenly overtakes the passive partner in the crime in the course of the unlawful operation to which she has submitted herself, leaving the other, the active agent, to be easily detected in the midst of his work, *flagrante delicto*, it is an opportunity which, if well improved, makes the dead woman a better witness against her accessory and herself than she could possibly be if living.

I offer the following cases as contributions to the somewhat scanty material which medical literature has accumulated in illustration of one variety of the sudden deaths to which I have referred, namely, as examples of those caused by the entrance of air into the circulation through uterine sinuses, freshly and forcibly opened. The general subject is still somewhat novel, while the infrequency of opportunities to investigate unequivocal cases of this kind with satisfactory fullness, justifies the presentation of those instances which have been the occasion for careful inquiry.[1]

CASE I. Minnie A. F., a married woman, twenty-three years old, whose marriage obligations had not controlled her chastity, was found dead late in the afternoon of July 2, 1881, in a bedroom of a house of ill-repute. She had come to the house in the middle of the previous night in company with a man, her paramour, and had passed the night there with him. In the morning the man went out, leaving the woman in the room, where she was seen, two hours later, by the housekeeper, alive and in bed. Just before noon the man returned and went to the room, remaining there about five minutes. As he went down stairs to go out he was observed to look about furtively as if desirous to elude notice. Two hours later he was readmitted to the house, and again he went to the room; he made a short stay, not more than five minutes, then disappeared from the premises for good.

At half-past six in the evening, the housekeeper went to the room to do the chamber-work, believing that the apartment was now vacant. She found the door unlocked, and, on entering, discovered the dead body of the girl in bed. When I saw the body, an hour later, there was nothing in its appearance or surroundings to suggest the cause or the manner of the death. The position gave no indication of violence or pain. The body lay in bed, turned a little on one side, the extremities disposed naturally as in sleep; a sheet and covelet were over it, and a chemise and stockings were the only articles of personal clothing upon it. The exposed parts — the face and upper extremities — were cold; the parts protected by bedclothing were cool, but still retained an appreciable degree of animal heat. Cadaveric rigidity was well developed, and there was an unusual amount of lividity about the face, neck, and dependent parts. The day had been hot. Considering all the data together, it seemed probable that the death had occurred about eight hours before the inspection of the body, or, in other words, coincidently with the man's morning call.

The body was removed for the purpose of determining by autopsy the cause of the death. And, to anticipate a little at this point, it may be stated that the autopsy revealed that which made it necessary to find the woman's partner of the previous night. In the course of their search, the detectives learned that, on the day after her death, her paramour, then many miles from Boston, had admitted to a friend that he had just used a catheter on Minnie for the purpose of causing her miscarriage, and when asked how she was, he had replied that "she was pretty well, he guessed." It also transpired that he had left Boston in haste in the afternoon of July 2d, the day of the death. The result was that this amateur abortionist, whose ordinary avocation was that of a village grocer, was arrested, indicted, tried, and convicted, and is now usefully employed at Concord in behalf of the Commonwealth. Of course, in his testimony at his trial, he protested that he knew nothing about Minnie's death; he had left her, he said, in bed, alive and well, but very tired from their previous day's trip to Nantasket. It thus happens that, in this case, we are without important facts which would be of great interest concerning the circumstances of the death, and the symptoms immediately preceding it. The examination of the body, however, left no doubt of the manner of the death, or of the avenue by which death approached, and it seems proper to give the post-mortem appearances with some attention to details.

The autopsy was made at half-past ten o'clock in the morning of July 3d, about twenty-three hours after the assumed time of the death, the body having been kept cool meanwhile. External examination failed to discover any sign of violence, nor were there any of the usual outward indications of pregnancy, such as enlargement of the abdomen, pigmentation of the areolæ, or milk in the breasts. There was no odor or other suggestion of decomposition in any part, external or internal.

The usual primary incision over the sternum revealed a clew to the whole case; out of the cut vessels there issued, instead of the expected drop of blood, a collection of minute bloody bubbles. When the pericardium was exposed by raising the sternum, it was unmistakable that the visible area of that sac in the anterior mediastinum was largely increased and bulging. The right cavities of the heart were distended, and gave to the fingers on palpation and percussion a distinct sensation of gaseous, instead of fluid, contents. A small puncture through the anterior wall of the right ventricle confirmed this impression; at first, a jet of odorless air escaped, followed presently by bloody bubbles, the distended right side of the heart meanwhile becoming flaccid. The left ventricle was contracted and empty. The structure of the heart was healthy.

The blood was dark and fluid; no clots were found in any part.

The inferior vena cava was distended with air throughout its extent, its thin walls rendering its inflated condition plainly visible.

The lungs were moderately reddened throughout

[1] These cases occurred to the writer in the course of his duty as a medical examiner in Suffolk County, Massachusetts, under the statute concerning the investigation of deaths by violence.

their anterior portions, their posterior and inferior, or dependent, parts showing considerable hypostatic engorgement, probably post mortem. Both lungs were crepitant in every part.

The kidneys weighed, the right six and a half ounces, the left seven ounces. They were injected; in other respects they were healthy in their gross appearances. The spleen was enlarged and engorged. The stomach and intestines showed nothing abnormal. The liver was normal in color, volume, weight, and consistency; bloody bubbles escaped freely from its divided vessels.

The pelvic organs presented the following appearances: The womb was enlarged to three times its unimpregnated volume. The veins of the uterine plexus and the iliac veins, especially those on the left side, were seen and felt to be filled mainly with air. The uterine cavity itself gave to the fingers applied externally the sensation of a layer of air outside more solid contents. There was no sign of violence about the external genitals or the vagina. The os uteri admitted the tip of the little finger part way through the cervical canal. Just within the external os the mucous membrane was reddened over an annular area two or three lines wide. When the section which exposed the cervical canal was extended along the front of the body of the uterus, the first cut through the uterine wall gave vent to a distinct puff of imprisoned air. Within the uterus was an ovum of about three months' growth, enveloped in its unbroken membranes. The long diameter of the embryonic sac was two and a half inches. The shaggy coat of the chorion was still present and displayed its typical appearances. The tufts of the chorion were very loosely adherent to the decidua, and the slightest force sufficed to separate the two surfaces. The immature placenta, of the size of a silver half-dollar, occupied a site at the upper and posterior part of the fundus; light pressure upon it gave the characteristic crepitant sign of air between it and the uterine tissue.

The color of the uterus and of its contents was normal, except that at the lowest part of the ovum, just above the internal os and in immediate relation with that orifice, there was an ecchymosed patch or streak, half an inch long and one eighth of an inch wide; at the right and most discolored end of this bruise there was a rent in the decidua, admitting freely, not to the cavity of the amnion, which was still entire, but to the space between the decidua and the chorion, and thus directly to the placental attachment. This rent could not be accurately measured, but its estimated dimensions were one inch in one direction and half an inch in another at right angles. It was evident that some instrument like a catheter had slipped upon the embryonic envelopes, making a bruise, and, instead of rupturing those membranes and setting free the liquor amnii, had glanced aside and torn up the decidual layers. Although no distinct separation of the placenta from the adjacent surface was demonstrated, it was seen that the uterine wall at the placental site was much redder than elsewhere. The cut surface of the uterus displayed many open orifices of divided sinuses.

Except moderate injection of the meningeal vessels and the presence of air-bubbles in the veins emptying into the great longitudinal sinus (which latter appearance might be accounted for in some way other than by the passage of air through the circulation), the brain and its membranes presented nothing abnormal.

Case II. Leontine R. J., aged twenty-one, single, and in good health, died suddenly in a physician's office in the afternoon of October 26, 1881, under the following circumstances: She was between seven and eight months pregnant, a fact which both she and the doctor knew, since the latter had himself determined on the previous 28th of June, to his own satisfaction, that the suppression of the girl's menstruation was due to her conception, which she presently confessed to him. In the first week of October she had told her sister of her pregnancy for the first time, and had said that she was going to have something done, and that Dr. —— was going to do it. The two sisters went to this physician's office in the afternoon of October 26th by appointment. He took the patient into an inner room, where there was a single bed suitable for gynæcological examinations. The sister remained in the larger room adjacent, and was so seated that she could not easily see or hear what transpired. It did not appear that any particular privacy was sought by the doctor or his patient; it was probably well known for what purpose the consultation was appointed, or, if not so, it was fully understood that the small room was designed and set apart for the physical examination of women, and all that was done there was recognized as in the line of the doctor's specialty by the servants as well as by callers at the house, — a bit of shrewdness which abortionists in general might find it profitable to copy. What occurred in the little bedroom is known only so far as it was described by the doctor at and before his trial; the missing links in the narrative must be left to the imagination or to logical inference. The following is a transcript of notes of the defendant's statement on the witness stand:[1] "Leontine said she wanted to talk with me, as she was not feeling well. As her sister was with her, I took Leontine into the little room. The sister took a seat in a large chair in the office. Twice or three times I went out. Leontine's drawers were off when I last went back to the room; I don't know when she took them off; I did not direct her to remove them. She complained of lassitude and bearing down. I told her I must make an examination. When I entered the room, and was preparing to make an examination, but before I had made any, she fell back in a faint. At my examination I introduced the finger into the vagina to ascertain the condition of the os, — to see if there were ulcerations there. I took no instrument and had no instrument of any kind in the little room." In the course of his cross-examination he declared that he made a digital examination to see if there was danger of a miscarriage; he "just felt around the os, but did not put his finger inside the os."

This account of the case, as given under oath, is not like the story which he related to me at my interview with him immediately after the death of his patient. At this time he said that Leontine went with him into the side-room and sat down with him on the edge of the bed. After being there about fifteen minutes, Leontine suddenly threw her hands above her head and fell back with a low moan or cry, then had a convulsion, with some frothing at the mouth, and became unconscious. At this time he denied making any examination, but declared that he asked questions only. He applied fruitlessly such restoratives as occurred to him; he put ammonia and water in the girl's mouth,

[1] The defense of the accused was conducted with great ability, but the trial resulted in his conviction.

but she failed to swallow the dose; he placed her feet and legs in hot water; and, finally, he attempted artificial respiration with the help of another doctor whom he had summoned, and who found the girl dead on his arrival. Imperfect as this account is of the facts relating to this death, it is still of value in showing the extreme suddenness of the fatal stroke.

The autopsy was made eighteen hours after the death, the weather being cool and the body having been kept in a cold room on a marble slab. Post-mortem rigidity was well marked, and there were patches of cadaveric lividity on the depending parts. There was no odor or other sign of decomposition, either externally or internally; indeed, the deeper parts of the abdomen still retained some warmth. The eyes were closed; the pupils were equal and measured three millimetres in diameter. The enlarged belly, the full breasts, the deeply pigmented areolæ, the presence of milk in the nipples, the firm tumor within the abdomen with its upper border just above the navel, — these were the indications of the pregnancy which the patient had conceded. About the fourchette, on the perinæum, along the nates, at each side of the perinæum, and on the clothing in immediate relation with these parts, there were blood-stains.

The primary incision along the sternum set free bloody bubbles from the openings of the divided vessels. When the sternum was raised the pericardium was seen to be very prominent, the edges of the lungs being quite widely parted in front. The right cavities of the heart were fully distended; to the touch they gave a sensation of elasticity difficult to describe, and on deeper pressure they conveyed a slight crepitant feeling. When a small puncture was made in the anterior wall of the right ventricle air escaped in a free jet, and without any perceptible odor. As the walls of the auricle and ventricle collapsed, bloody bubbles exuded upon the application of the slightest external pressure. The left ventricle was firmly contracted and empty. The superficial veins of the heart contained interrupted columns of air and blood. The size and structure of the heart were normal, and wholly disproved the theory of the patient's physician that her death was due to "heart disease." The blood was dark and fluid. The lungs were hyperæmic, the posterior and inferior portions especially so. The bronchial mucous membrane was injected. There were no sub-pleural punctate ecchymoses.

The kidneys were injected, but showed nothing abnormal in other respects. The liver was healthy; air-bubbles issued from its cut vessels. The veins of the mesentery contained air in abundance. The inferior vena cava held very little blood, but was seen and felt to be filled almost wholly with air.

The brain and its membranes presented nothing remarkable beyond the presence of air in the meningeal veins and in the venæ Galeni.

Before removal of the pelvic organs from the body, the uterus was carefully examined *in situ;* its enlarged size permitted satisfactory inspection. Its color anteriorly was normal, but its left lateral and posterior regions were injected. The tortuous venous sinuses could be distinctly traced in the uterine tissue, standing out prominently in all directions; they were not corded and tense as if over-distended with blood, but were yielding and elastic. Upon palpation the left lateral region of the womb gave a distinct impression of a quantity of air collected between the womb and the fœtus, whose limbs could be readily felt through the enveloping uterine walls and amniotic sac. The left utero-vaginal plexus of veins was fully distended with air, and the superficial veins of the body of the womb were seen to be similarly filled.

The uterus, rectum, vagina, and bladder having been removed together, the following appearances were noted: At the upper or sub-pubic margin of the ostium vaginæ, near the urinary meatus, there was an ecchymosis, half an inch long and one eighth of an inch wide, and readily referable to pressure by an inelastic instrument upon the tissues covering the pubic arch.

The os externum of the womb admitted the thumb easily. Just within the posterior lip the mucous membrane of the cervical canal was reddened, while the inner margin of the os showed a chain of minute vesicles on a reddened base. The cervical canal contained a quantity of tenacious, blood-stained mucus. The fœtal membranes had been stripped away before death from the left lateral and posterior surface of the womb, involving fully one half of the entire inner uterine area, and leaving a cavity or reservoir which contained air and about four fluid ounces of dark-colored fluid blood. That this forcible separation of the two surfaces had occurred during life was demonstrated by the deeply reddened color of the uterine lining involved in the lesion, and by the following specially significant appearance: upon the inner surface of the womb, posteriorly, there was an ecchymosis, pyriform in general shape, its narrow part at the inner os being half an inch in diameter, its length extending toward the fundus five inches, and its widest part at its upper limit an inch and a half. This ecchymosed area, taken in connection with the bruise at the upper part of the vaginal outlet, and the limited reddening of the cervical mucous membrane, offered but little difficulty for its explanation; nothing could account for it so well as that a sound or catheter or other similar instrument had been introduced through the os uteri, and instead of penetrating the fœtal sac had slipped backward and downward, passing between the membranes and the womb, whose opposing surfaces were violently separated thereby. But the mischief did not end with this forcible sundering of adhesions not yet mature for divorce. In every part of the denuded uterine surface the presence of open sinuses was demonstrable, not only by the escape, on light pressure, of bubbles from their patulous orifices, but by means of a blow-pipe, with which instrument air could readily be blown through the ruptured canals into the external venous plexus.

The amniotic sac was entire; it contained a female fœtus weighing two pounds, and measuring fourteen inches; its development was normal in all respects. The placenta was attached at the fundus, a little to the right of the centre, and out of reach of the violence above described. The uterus measured ten inches in depth, and its wall varied in thickness from a quarter to half an inch. The right ovary contained a small corpus luteum.

These two cases owe their chief interest and significance to their necroscopic appearances, and these appearances invite a few words of comment in conclusion. The necessary limits of this paper will forbid that anything more than a mere outline sketch of the general subject be presented, and many attractive points must be wholly neglected or simply suggested. The most

striking feature which these examinations brought to view was the astonishing volume of air which had entered the circulatory apparatus, displacing the blood, and giving a characteristically inflated condition to the parts chiefly invaded, — the uterine sinuses, the veins issuing from the pelvis, the inferior vena cava, and the right cavities of the heart. It would seem incredible that so great an amount of air could enter the body and be stored up in the circulatory channels in the brief time known or assumed to be included in the entire course of the attack. So, too, the distribution of the intruding agent through the body offers another remarkable feature. The air was not found in the parts nearest its point of entrance only, the pelvic veins and the vena cava, but it had penetrated to the heart and far beyond, and was discovered in situations which it must have reached through the systemic circulation, — in the small vessels of the subcutaneous tissues over the sternum, in the liver and the mesenteric veins, and in the meningeal veins.[1] Such a large volume of air, so widely distributed, suggests the element of time in connection with the fatal process, and gives pertinence to the question, How is it possible that death could follow very quickly upon the first entrance of air into the circulation? The apparent difficulties attending this question are much modified if one or two facts are remembered in their relation thereto. In the first place we are assured by physiologists that the round of the systemic circulation is made with almost incredible rapidity; if we accept the latest views, that the blood completes its circuit in from twenty to twenty-five seconds, we are less embarrassed by this seeming inconsistency of clinical observations and anatomical appearances. Then, again, it is probable that the fatal result, though appallingly sudden, is not actually instantaneous; the patient's apparent death, as indicated by irremediable insensibility and apnœa, is probably attended, in the majority of cases, by an action of the heart, spasmodic and irregular, but continued for some time after the other vital functions have succumbed, and the process of dying seems practically consummated. Erichsen,[2] many years ago, determined this continued cardiac action experimentally, and clinical facts are not wanting to the same purpose. Indeed, in the second of the two cases related in this paper, the attending physician declared that he felt the pulse beating several minutes after the respiration stopped. Moreover, it is probable that restorative measures, like artificial respiration, might help to introduce some further supplies of air into the veins after the natural forces of the body were no longer operative.

But, whatever the difficulties which may be in the way of a full explanation of the post-mortem appearances, of one thing there can be no doubt; the presence of so much air in channels normally occupied by blood is the one unequivocal cause of death. Observing the great accumulation of this agent in various parts of the body, and especially in the one part so essential to life (the heart); observing, too, that all the organs are free from disease or decomposition, and present no departures from the normal condition other than those pertaining to recent and grave disturbance of the general circulation, the examiner can have no hesitation in reaching his diagnosis of the cause of death. And it is interesting to remember that by whatever venous channel the air has found its way to the heart, the result is the same, and the appearances are identical. Whether, through a surgical mishap, a vein in the neck, or in the axilla, or about the shoulder has been divided, whose anatomical relations have kept its walls open and free to admit the air; or the recently delivered woman rising abruptly from her bed has given an entrance to the atmosphere through the patulous mouths of her uterine sinuses by her change of posture; or the same canals have been exposed to the same accident through the manipulations of the abortionist, as in the instances above reported; or the gynæcologist, endeavoring to dislodge or simply to explore a fibroid tumor growing in the attenuated uterine wall, has the misfortune to produce a favoring solution of continuity, — in all these cases the appearances left in the body by the fatal intrusion of air are essentially the same in character and degree; and of all these appearances, the inflated state of the right auricle and ventricle are the most significant and uniform. Nysten, whose observations and experiments on this subject were careful and exhaustive, declares that when death is the speedy consequence of the entrance of air into the organs of circulation, the right auricle is always found distended with frothy blood;[3] and Amussat, in a report upon the introduction of air into the veins, which he read before the Royal Academy of Medicine in Paris, uses this very decided language with reference to the state of the heart:[4] "We invariably find the right cavities of the heart distended." Nearly all the later authorities whom I have been able to consult concur in this regard, so that we may consider this easily recognized condition as a reliable characteristic sign of this form of death.

(*To be concluded.*)

[1] It is possible that the air-bubbles in the meningeal veins were formed when the calvaria and dura mater were removed; this possibility will be the more readily admitted since it reduces by so much the difficulty of accounting for air in vessels remote from the heart, and on the wrong side of that organ.

RECENT PROGRESS IN SURGERY.

BY H. H. A. BEACH, M. D.

STRICTURE OF THE ŒSOPHAGUS.[5]

Mr. T. Holmes reports the case and discusses the advantages of gastrostomy and œsophagostomy (so called to distinguish the operation from the ordinary one of œsophagotomy for the purpose of removing foreign bodies). The disease was thought to be epithelioma, probably infiltrating the œsophagus and spreading into the tissues external to the larynx. It was also thought that the œsophagus could be opened below the tumor. The operation was almost bloodless; some difficulty was experienced in attempting to separate the trachea from the œsophagus. The thyroid body was the source of some embarrassment on account of its size and vascularity. The patient sank on the third day after the operation, although he had been fed with perfect comfort every three hours, and later more frequently. Very little food was rejected. He was conscious and free from pain.

At the post-mortem examination all the parts about the wound were found perfectly quiet, and union seemed to be going on well. In reviewing the details

[5] London Medical Times and Gazette.

Mr. Holmes concludes that the operation was justifiable, and that it might have been successful in its object. Upon the question of dilatation he remarks as follows: "To irritate a cancerous stricture (as I believe this was) by frequent passage of instruments can only do harm. Thus Billroth says, the daily dilatation with the bougie for carcinomatous strictures is the only thing that we can do to preserve the patient from death by starvation. I am certain, however, that this daily stretching and irritation of the carcinoma hastens its softening. We have now learned that the œsophagus will, at any rate sometimes, tolerate the prolonged retention of a tube; but in the case before us, the passage of the tube having been found impracticable without a dangerous amount of force, there remained only the alternative between opening the stomach or the œsophagus, if anything was to be done. Now the opening of the œsophagus seems to me a much less dangerous operation, if once its anatomical difficulties are got over, and I am confirmed in this opinion by the experience of cases of cut-throat.

"It is not possible to be sure of the extent of the disease in the œsophagus; and though of course an opening might possibly be made through a part infiltrated with disease, yet such a proceeding would be very unsatisfactory. The proximity of the recurrent laryngeal nerve is another element of danger, though I do not think it is a serious one. And so is the presence of the numerous vessels of the thyroid body. These dangers are best avoided by great deliberation in the dissection, so that the nerve, if seen, can be drawn aside, and the vessels ligatured in two places and divided, as was done in this instance. Another objection is the difficulty that may exist in drawing up the œsophagus to the skin, — a difficulty which was found in this case insuperable (I see that it was the same with Mr. Reeve's case). How far this would have proved an obstacle to the successful treatment of the case, the man's death on the third day prevented me from judging. It was my intention to leave the india-rubber canula in position for at least a week; and I hoped that by that time the parts would be sufficiently consolidated to allow us to change it for another without any trouble, and so that the man could wear the canula permanently and thus easily feed himself.

"On the whole, the case convinced me of the feasibility of the treatment, and has led me to think that it is superior in many respects to gastrostomy, though its range of application may be more limited. Further experience will no doubt soon show surgeons what the relative merits of the two operations are."

LIGATURE OF THE INNOMINATE.[1]

Mr. William Thompson, of Dublin, furnishes the following particulars, which conclude the history of his very interesting case of aneurism: "My patient," he says, "died on the forty-second day after ligature of the innominate. There was no recurrence of bleeding after the thirty-ninth day. The sinus was found to terminate in an ulcer which involved the anterior wall of the junction of the subclavian, carotid, and innominate arteries. The innominate and carotid arteries were filled with clot; the subclavian contained a clot occluding it to the extent of half an inch. The position of the ulcer was on the distal side of the ligature, the constricted portion of the innominate not being involved. The hæmorrhage had apparently taken place from the innominate, as there was a recent blood-stain on the cardiac side of the clot. None of the vessels were pervious to water forced in with a syringe. The aorta was atheromatous. Consolidation was proceeding satisfactorily in the tumor. This is the second longest survival (except Smyth's case, which recovered) on record, Graefe's case having reached the sixty-seventh day, and Cooper's the thirty-fourth."

[1] London Lancet.

SYPHILIS CONVEYED BY SKIN GRAFTS.[2]

The case occurred in Paris, and is reported by M. Féréol.

"The patient was a man aged forty-nine, who had not had any venereal affection, and who had a large wound caused by erysipelas, with sloughing. Seventy-five dermo-epidermic grafts were put on, nearly all of which "took," and cicatrization was rapidly effected. A month after the application of the first grafts the cicatrix began to ulcerate in several places. Six weeks later an abundant roseolous eruption broke out over the body, and a month later mucous patches appeared in the mouth. One of the sons of the man who had furnished grafts on each occasion then consulted M. Deubel for mucous patches about the anus, and stated that eighteen months previously he had had a hard chancre, for which he had not had any treatment. The case is apparently beyond all doubt, and shows the necessity for caution in the selection of persons from whom grafts are taken. The safest rule to follow is, wherever possible, to take the grafts from the person on whom they are to be implanted."

[2] London Lancet.

BORO-GLYCERIDE IN OPERATIVE SURGERY.[3]

Mr. Richard Barwell presented a paper upon this subject at a recent meeting of the British Medical Association, in which he dwelt upon the topical and general poisonous action of carbolic acid. He states that thymol in his hands had entirely failed, and that eucalyptus had not answered his expectations. He had found boracic acid reliable, but very unmanageable. Professor Barf's lecture on the preservative qualities of boro-glyceride suggested its use as a surgical dressing. He reports twelve cases which were good tests of the dressing, and showed it to be a reliable antiseptic. The fact that no spray is required during operating or dressing, and that the latter is so simple and so easily applied, makes the method an attractive one, both for hospital and private service.

[3] British Medical Journal.

CONGENITAL INGUINAL HERNIA IN THE MALE.[4]

"Dr. Kraske gives the following summary of Volkmann's practice with a view to radical cure: —

"(1.) If, in cases of congenital scrotal hernia, the neck of the sac can be isolated, a ligature may be applied around this. In addition to the deligation of the sac, which may be combined with apposition of the pillars of the ring by sutures, the surgeon should also, according to the indications of each case, wash out and drain the interior of the sac, and practice simple transverse section or partial excision of this membrane.

"(2.) The isolation of the hernial sac is very frequently impossible in cases of congenital scrotal rupture. Sometimes the elements of the cord are separated. When the sac cannot be isolated, the surgeon may apply a quitting suture, as recommended by

[4] London Medical Record.

Wahl, or follow Schede's practice, by plugging the ring with a stump of omentum, and subsequently disinfecting and draining the sac. These proceedings, however, can only be applied under certain circumstances. In difficult cases one should consider the advisability of resorting to castration, an operation which may be the more readily adopted the smaller one finds the testis and the older the patient.

"(3.) In cases of congenital inguinal hernia, complicated with incomplete descent of the testis, the surgeon, if the sac — the vaginal process — can be isolated, may ligature the neck of this, cut across the membrane, and endeavor to bring down the testis into the scrotum. If the sac cannot be isolated, then castration should be performed. When the patient is advanced in years this latter operation may be regarded as the simplest and most certain method under any circumstances."

VESICO-VAGINAL FISTULA; COMPLETE CURE WITHOUT AN OPERATION.

This unique case was admitted at the Sussex County Hospital, Brighton, and was under the care of Mr. Powers, who makes the following report of it in the London *Lancet*: —

Patient aged thirty-nine. Ten weeks before admission she was confined for the sixth time; the labor was more difficult than the previous ones, and lasted forty-eight hours; forceps were used. On the ninth day after the operation urine dribbled away for the first time. On admission there was a vesico-vaginal fistula at the very top of the anterior wall of the vagina. The opening was ragged, with cicatricial borders, and large enough to admit the tip of a man's forefinger. A female catheter was passed into the bladder, through the fistula into the vagina. The anterior lip of the os uteri appeared to have been destroyed, and the os uteri itself was left somewhat patent. On July 7th a soft catheter was tied in, and the patient was kept in the prone position. 21st. Owing to obstinate diarrhœa, the catheter has been withdrawn. 24th. The catheter has again been tied into the bladder to-day. 28th. The catheter has slipped out during the night. She affirms that much less urine runs away from the vagina, and also that she has passed several ounces voluntarily at one sitting. 31st. Catheter again tied in.

August 4th. Catheter removed this morning. She says that no urine runs away. 18th. As a small quantity of urine is again escaping, the catheter is to be tied in once more. 20th. The patient is menstruating. The catheter has been removed. No urine escaping. 25th. The patient was instructed never to empty her bladder herself. The urine is drawn off four times in twenty-four hours. She keeps her bed. The sheets are never wet or stained. September 1st. She now gets up, and has complete control over the bladder. 6th. The patient was discharged.

GRAFTING SKIN FROM A RABBIT.[1]

"Dr. Lamallerée, of Paris, has recently employed grafts from the skin of the rabbit to excite cicatrization in the human subject.[2] The patient had suffered for six years from a varicose ulcer of the leg, which had resisted all sorts of treatment. Six bits of skin from the belly (previously shaved) of a rabbit, and two from the skin of the human fore-arm, were grafted on the surface of the granulating ulcer, with the proper antiseptic precautions. At the end of eight days the pieces of skin from the rodent had taken root and were growing, those from the man had not. After eight days more an island of new skin was to be seen (ten centimetres long and seven wide) in the centre of the sore. The healing went on to complete cicatrization, and the newly-formed epidermis evinced no trace of its lowly origin."

OBTURATOR HERNIA.[3]

The case is reported by Dr. Grünberg, of Stralsund. "The patient was a woman, aged sixty-five, who, during the three days before she came under observation, had suffered from well-marked and very intense symptoms of intestinal strangulation. No swelling could be made out at any of the usual seats of hernia, but on close examination it was found that pressure just below the left groin and over the pectineus muscle caused great pain. A vertical incision, about three inches in length, commencing just below the horizontal ramus of the os pubis, was carried downwards at a distance of an inch and a quarter from the outer border of the adductor longus. On exposure of the surface of the pectineus, no swelling nor abnormality was observed, but on raising the outer margin of this muscle, and drawing it inwards, a hernial tumor of the size of a large hazel-nut was revealed. After incision of the wall of the sac on a director a small loop of intestine came to view, which, though very lightly constricted, and of dark-blue color, presented a smooth and shining surface, and had evidently not become gangrenous. For fear of wounding the obturator artery, the pulsations of which could be felt by the finger, the knife was not used for overcoming the stricture. The orifice constricting the neck of the hernia was dilated by the forefinger, being carried along the outer and lower portion of its circumference, and also by breaking down some of the fibres of the obturator membrane. All the symptoms of strangulation ceased immediately after the operation, and on the eighteenth day the patient, though feeble, was regarded as cured. Two days later, however, according to a postscript, she died suddenly with symptoms of collapse, in consequence of perforation of the intestine. Dr. Grünberg states that it is not clear to him why almost all the writers on obturator hernia have reported its diagnosis as being very difficult. He holds that the diagnosis of a strangulated obturator hernia is not more difficult than that of a strangulated femoral hernia. No tumor, it is true, is to be seen or felt, but then there is always characteristic pain. In some instances there is lancinating pain caused by pressure on the obturator nerve. In Dr. Grünberg's case any attempt at active flexion of the thigh excited very intense pain, and the patient complained of constant painful and pricking sensations extending down the inner side of the thigh. This pain, due to the pressure on the nerve, however, is not always felt in cases of obturator hernia, and is frequently complained of by the subjects of uterine disease and also by hysterical women. The characteristic pain of strangulated obturator hernia, and that by which the diagnosis may be readily and surely established, is the tenderness complained of when pressure is made over the pectineus muscle. This tenderness, the region of which is very limited in extent, is so intense that the patient screams when it is excited, and,

[1] London Medical Times and Gazette.
[2] Deutsch Med. Zeit., No. 40.
[3] London Medical Record.

if under the influence of an anæsthetic, shrinks on pressure over this tender part. When this characteristic pain over the locality of the obturator canal can be made out in association with the symptoms of intestinal strangulation, Dr. Grünberg holds that one may safely diagnosticate obturator hernia. On the other hand, in absence of such pain, he would decide with equal confidence against the existence of this affection. Notwithstanding the success that attended non-operative treatment in the well-known case reported by Roser in 1845, Dr. Grünberg would not expect much from the taxis in any case of strangulated obturator hernia, the hernial tumor is so very small, and reflex contraction of the surrounding muscles is so liable to be set up on manipulation. If not strangulated the hernia might return spontaneously under the influence of alternating natural contraction and relaxation of the adductors and flexors of the thigh.

The operation for relief of the hernia when strangulated, if performed early, is free from danger. Dr. Grünberg recommends that in order to avoid bleeding from the muscular vessels, the pectineus, instead of being partially divided, should be raised, and then dragged inwards by blunt hooks. Should the hernial tumor be large, so as to necessitate division of the muscle, it is recommended that it be separated at its origin from the ramus of the pubis by the use of a tenotome. The constriction, it is held, may usually be overcome by passing the tip of the forefinger with a gentle boring movement between the neck of the sac and the membranous portion of the constricting ring, dilatation being effected partly through yielding of the obturator membrane, and partly through tearing of some of its fibres. Hæmorrhage from the obturator artery will be thus avoided. If the superficial incision be made according to Dr. Grünberg's direction there is no danger, he says, of wounding the internal saphenous vein. The incision he recommends is one about three inches in length, commencing just below the horizontal ramus of the pubis, at a point about one inch and a quarter to the outer side of the origin of the stretched adductor longus, and carried directly downwards over the outer margin of the pectineus."

REMOVAL OF THE STERNUM.[1]

Professor König, of Göttingen, related a case and exhibited the patient, after recovery, before the surgical section of the German Association. The bone was removed on account of a sarcomatous growth. In the course of the operation both pleural cavities were opened, also the pericardium, the growth having become adherent to that membrane. The wound was dressed antiseptically, and the only disturbance following was some dyspnœa for a short time. Upon removing the first dressing at the end of twelve days one of the flaps was found gangrenous, and the heart surrounded with pus. The healing process was a slow one.

TREATMENT OF HYDRARTHROSES.[2]

"Professor Volkmann observes that, in reference to a discussion of the subject at the Paris Société de Chirurgie, that both puncturing and washing out the joint, and the double incision and drainage, with the antiseptics, may be declared to be operations unattended with danger, and followed by satisfactory results."

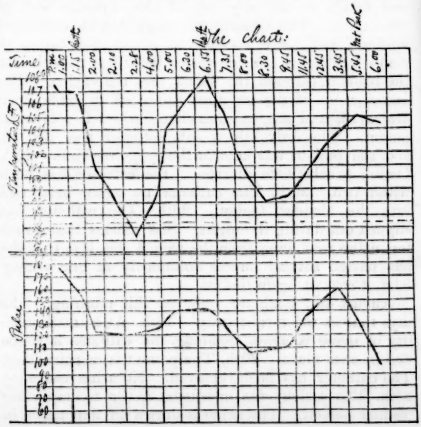
ANTISEPTICISM IN OVARIOTOMY.

As bearing upon the question of this dressing in general surgery, Mr. Lawson Tait's report of one hundred consecutive cases, with only three deaths, demands consideration. The operations were performed without any of the Listerian details, and are published in the *British Medical Journal* for October 28, 1882.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.



CASES IN THE SERVICE OF DR. GEORGE B. SHATTUCK.

REPORTED BY CHARLES D. SAWIN, MEDICAL HOUSE OFFICER.

CASE I. SUNSTROKE. DEATH.

T. C., a stevedore, about fifty years of age, was admitted to the hospital at one o'clock P. M., July 27, 1882, having lain for a considerable length of time exposed to the sun's rays, and becoming insensible and comatose. Skin very hot and dry. Pupils very much contracted and feebly responsive to light. While on the way to the hospital, and after his arrival, he was subject to constant involuntary dejections, which continued up to the time of his death. Temperature by rectum was 107.4° F., pulse 175, and quite full.

He was immediately submerged in water at a temperature of 80° F., which was cooled down in the

course of thirty minutes to 55° F. At 1.15 o'clock the temperature by rectum was 107° F., and the pulse 160. Five grains of hydrobromate of quinia were now administered hypodermically. Soon he became restless, and more or less force was required to keep him in the bath-tub. At 1.30 the same dose of quinia was repeated, and at two o'clock, after having been in the bath fifty minutes, he was removed, the temperature by rectum being 101.2° F. Pulse showed at this point much weakness. Blankets and heaters were now applied, and the cutaneous surface rubbed vigorously. Temperature continued to fall until it was 95.3° F. Various methods of stimulation, including hypo-

dermic injections of brandy, were now resorted to; soon, however, the increasing heat again manifested itself, and, as seen by the accompanying chart, the temperature rose to 108° F. Heaters were now removed, and patient again immersed in water at a temperature of 70° F., which was, as before, slowly cooled down to 55° F. This time the bodily temperature did not fall so readily, and after forty minutes he was taken out, having a temperature of 104.4° F., which continued to fall until it was 98° F. Pulse 110, and of good quality.

Patient now quite comfortable, and seemed to sleep for a few hours.

An unexpected third rise, however, soon began, and the pulse already was exhibiting many signs of weakness. Tincture of digitalis (fifteen minims) and brandy were now given hypodermically. At five o'clock A. M. (28th) the temperature was 105° F., and on account of the extreme cardiac exhaustion the method of reduction of temperature by the wet-pack was resorted to in lieu of the tub-bath. It proved of little avail, though, for death supervened in the course of half an hour thereafter.

It may, perhaps, be of some little interest to add a table showing the thermal condition of the atmosphere for several days previous to and on the day of the occurrence of the above-described case, as illustrating the fact that the tendency to sunstroke seems to depend rather upon a continuance of a high temperature for several successive days: —

	July 23.	July 24.	July 25.	July 26.	July 27.
Mean temperature.	74°	79°	81°	82°	79°
Maximum . . .	88°	95°	96°	95°	98°
Minimum . . .	62°	67°	69°	71°	68°

CASE II. SUNSTROKE. RECOVERY.

B. R., aged thirty-four, a carpenter by occupation, was compelled by reason of his peculiar work to remain out-of-doors exposed to the sun a great deal, and on August 9th, after having labored till eleven o'clock A. M., was obliged to stop on account of increasing weakness, dizziness, and a tired sensation in his lower extremities. He then went to bed, but he could not sleep, and dressing went out for a walk. What followed he knew little about, but he remembered being on Harrison Avenue. Just previous to the attack he was seized with "a terrible lonesome" feeling, and objects about him seemed to be bluish in appearance.

Admitted to the hospital about half past five o'clock P. M. in an unconscious condition, with pupils dilated, and breathing heavily. Temperature by rectum was 108.8° F., and pulse 145. Patient was placed in a bath-tub, the water in which was at a temperature of 77° F., and at this point the temperature was maintained throughout by means of the addition of small pieces of ice from time to time. In the short space of thirty minutes the body heat as indicated by the thermometer was 103° F., and the patient was then taken out. The pulse evinced much strength and regularity till about six o'clock, when the number of beats increased to 180, although the temperature at this time was nearly normal. Ten minims of tincture of digitalis were given hypodermically, and an excellent result noted shortly afterwards.

There was another slight rise of temperature, but not excessive, as will be seen by the accompanying chart, and sponge baths were given at frequent intervals to prevent such occurring, if possible.

The slight attack of diarrhœa, which was noted on entrance, ceased, the pulse became more natural, and at eight o'clock he became quiet and semiconscious. Slept well after eleven o'clock P. M., though waking occasionally and talking in a rational and pleasant manner. In the morning complained of a feeling of constriction about the head. On the next day fully convalescent. Discharged, well, on the 12th of August.

As in the preceding instance, the accompanying table will furnish facts relative to the condition of the atmosphere: —

	August 6.	August 7.	August 8.	August 9.
Mean temperature . . .	74°	78°	78°	79°
Maximum	97°	88°	92°	89°
Minimum	67°	71°	70°	68°

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

PRESENTATION OF A BUST OF THE LATE PROFESSOR WHITE, OF BUFFALO.

Stated meeting, December 21, 1882. Dr. Austin Flint presented a marble bust of the late Dr. James P. White, President and Professor of Obstetrics and Gynæcology of the University of Buffalo, and a non-resident Fellow of the Academy, on behalf of Mr. James Platt White, the son of the latter. The bust is admirable as a likeness, as well as successful as a work of art, and was executed by J. S. Mitchell, the Rochester sculptor. Dr. Flint was formerly associated with Dr. White in the Faculty of the Buffalo University, and was a life-long friend of his. At the conclu-

sion of his presentation address he proposed a set of appropriate resolutions accepting the gift and returning the thanks of the Academy to the donor, which, after they had been seconded by Dr. T. Gaillard Thomas, in a few eulogistic remarks, were unanimously adopted.

DR. THOMAS then read a paper entitled

A CONTRIBUTION TO THE SUBJECT OF REMOVAL OF THE UTERINE APPENDAGES (TAIT'S OPERATION), FOR RECURRENT PELVIC INFLAMMATIONS.

He commenced by alluding to the remarkable essay of Lawson Tait, of Birmingham, published in the *British Medical Journal* of July 29, 1882, entitled: Remarks on the Diagnosis and Treatment of Chronic Inflammation of the Ovary, and said that it was in accordance with the principles there enunciated that he had undertaken to operate in the four cases to be narrated in the present paper. In it Mr. Tait had advanced views which were destined to open a new field to the gynæcologist, and which would undoubtedly exert an enduring influence. He did not feel warranted in accepting all the opinions expressed by the writer, but he certainly recognized the paper as one of the most valuable contributions to gynæcological science made during the present decade. While the uterus, the uterine ligaments, and the pelvic areolar tissue had been studied with the greatest care by the gynæcologists of Europe and America, the affections of the ovaries and Fallopian tubes had been left almost completely shrouded in mystery, and Dr. Tait had been almost alone in his investigations of this subject. How often had it been found that after a long course of treatment of the uterus, including all the mechanical devices and operative procedures that the most skillful gynæcologist could devise, the condition of the patient remained substantially the same, and the case had to be finally abandoned as incurable. He was glad to say, however, that a wholesome revolution in regard to the attention paid to the ovaries now seemed to be taking place.

Dr. Thomas then proceeded to recapitulate some of the most original and valuable of the points advanced by Mr. Tait, as follows: (1.) Formerly it had been felt that the surgeon was not justified in opening the abdomen for conditions whose severity did not threaten life, and the removal of ovarian tumors was consequently delayed as long as possible by means of mischievous tappings; but now, when the removal of an ovarian tumor was fatal only when the patient had been tapped, or the operation injudiciously delayed, we were justified in performing abdominal section, not merely for the saving of life, but for the relief of suffering. (2.) The usually accepted doctrine of the coincidence of ovulation and menstruation was wholly erroneous. (3.) The ovaries had nothing whatever to do with menstruation; the phenomena of menstruation depending upon the Fallopian tubes, and not upon the ovaries. (4.) In many cases of abnormal menstruation extirpation of the ovaries and Fallopian tubes put an end to the sufferings of the patient. (5.) In chronic ovaritis the tubes were always involved. (6.) In his last thirty-five cases there had been only one death, a mortality of 2.85 per cent. after operation. (7.) Recurrent pelvic inflammations were generally attributable to tubal dropsy and ovarian disease. This last proposition was not found in Mr. Tait's essay, but had been mentioned by him in conversation with Dr. T. A. Emmet, of New York, during the past summer.

The subject at present under discussion, Dr. Thomas went on to say, had nothing whatever to do with the removal of ovarian tumors — the operation in question being performed for the relief of the suffering and removal of the dangers incident to chronic ovaritis and salpingitis, and to recurrent attacks of pelvic inflammation. The history of oöphorectomy was so brief that it might be said to be still in its infancy. It was first performed by Hegar in July, 1872, and five days later by Tait. Neither of these operations was published, and neither operator was aware of the other's having done it. During the very next month, Battey, of Georgia, performed it and published it as an original operation, and to him the credit of the procedure had been justly conceded. The operation to which Tait laid claim was the removal of the Fallopian tubes in addition to the ovaries. This he believed to be essential, because his experience convinced him that salpingitis and tubal dropsy were invariably present in connection with ovarian inflammation, and constituted the more serious trouble of the two.

Dr. Thomas said that he had performed Tait's operation in four cases, but that they were as yet entirely too recent to show permanent results; and he then proceeded to narrate them in detail. The first patient was a negress, thirty years of age, and married, who for a considerable time had had an attack of pelvic cellulitis or peritonitis about once a year, and in consequence had become a chronic invalid. During the past eighteen months she had suffered the most intense pain over both ovaries, and for six months had had profuse hæmorrhage at her menstrual periods. The uterus was found to be large and anteverted. Under the supposition that the endometrium was probably covered with a growth of fungoid excrescences, which gave rise to the menorrhagia, he carefully scraped the uterine cavity with the copper wire curette; but, to his surprise, he found that there were scarcely any of these fungous growths present. He then introduced an anteversion pessary, but this only resulted in positive harm. A more careful physical examination now led him to the conclusion that there was chronic inflammation of the ovaries and Fallopian tubes, and, despairing of affording relief to the patient in any other way, he made an abdominal incision in the median line and performed Tait's operation, the strictest antiseptic measures being adopted, with the exception of the spray. The ovaries were found to be covered with small cysts, while the tubes were enormously distended with fluid, giving them the appearance of sausages, and pouring forth a purulent discharge from their lining membrane. (The specimens were exhibited to the Academy.) The operation was not followed by the slightest unfavorable symptoms, and on the thirteenth day after it the patient sat up. Since then there had been no return whatever of the menstrual flow, and the woman seemed quite well.

The second patient was a lady twenty-five years of age, who had been married three years, and had had one child eighteen months before. Nine months after her confinement she had had an attack of pelvic inflammation (either cellulitis or peritonitis), and had never been well since. She suffered mainly from intense pelvic pain and irregular and profuse menstruation. The left ovary was found to be as large as a hen's egg, and exquisitely sensitive to the touch. An exploratory abdominal incision was made, and both ovaries and both Fallopian tubes being found to be diseased were removed. The operation was a difficult one on account

of the firm adhesions that were present. (These specimens were also exhibited, and the tubes were seen to be greatly enlarged.) The patient made a good recovery, and had not menstruated since the operation.

The third case was that of an unmarried lady of twenty-two. From the age of fourteen, when menstruation commenced, she had suffered from the most extreme dysmenorrhœa. For the past year the pain had been almost constant, although not so severe as at the time of her periods, when it was necessary to semi-narcotize her in order to give her any ease at all. In addition to the pain, she suffered from extreme exhaustion, and her physician stated that sometimes for hours during her periods the pulse was wholly, or almost, imperceptible at the wrist; so that he feared a fatal result. Dr. Thomas removed both ovaries, which were cystic, and both tubes, which were greatly enlarged, and the lining membrane of which was filled with pus; though there was not as much dropsy as in the other two cases. The specimens had, unfortunately, been lost. Since the operation the patient had passed one menstrual period, and there had been no discharge.

The fourth operation was followed by a fatal result; but the patient, who was unmarried and twenty-seven years of age, was in a state of extreme exhaustion at the time. From the age of fourteen she had suffered from severe dysmenorrhœa, but during the last two years she had had in addition repeated attacks of pelvic inflammation, which caused her the most intense suffering. For a month he endeavored to build up her vital powers; but finding this impossible, he decided not to delay any longer with surgical interference, and, accordingly, performed Tait's operation. At the time she looked precisely like a patient in the third stage of pulmonary phthisis, so great was her pallor and emaciation. Her temperature was 100, her pulse 150, and she was harassed by never-ending pelvic pain. The operation was performed on the 11th of December, and was very tedious and difficult, as the ovaries, which were covered with small cysts, and the tubes, which were dropsical, were firmly bound down by false membranes. (Specimens exhibited.) The prognosis was very unfavorable, and within twenty-four hours after the operation an insidious attack of peritonitis, with low temperature and accompanied by little pain, set in, and the patient died on the sixth day.

This, Dr. Thomas said, was all his experience, and he could not but regret that the remote results of his cases were not yet attainable. All that he had done was simply an attempt to uphold the hands of a bold and original investigator. The results of Tait's operations were exceedingly gratifying. In his seventy-five cases there had been six deaths. This embraced his whole experience with the operation. Confining it to the cases of chronic ovaritis he had lost only one case out of thirty-five. Battey had lost three out of fifteen cases, while he himself had lost four out of twenty-one. The fact was undoubted that laparotomy was more successfully performed in Europe than in America, where the operation originated. This was a reproach to American surgeons, and the discrepancy in favor of the European operators was one which could not be met with arguments, and was only to be abolished by results.

There was no discussion of Dr. Thomas's paper on this occasion, but Dr. Emmet, being called upon by the chair to give his impressions of Mr. Tait's methods and opinions, said that in his recent visit to Birmingham, he was not fortunate enough to have an opportunity of seeing Tait operate, but he saw a number of the cases which had been operated upon, as well as the specimens removed, and nothing that he met with abroad had interested him so much and puzzled him so much. In the English surgeon's laboratory there were specimens from about sixty cases in which he had operated during the past eighteen months, and what surprised him most was their large number. Where could so many such cases possibly come from, was the question that puzzled him. He had had the opportunity of examining many dead bodies of women in the hospitals, and he had certainly never met with the condition seen in these specimens more than a dozen times altogether. Mr. Tait told him that he was now accustomed to operate in all old cases of ovaritis and pelvic cellulitis and peritonitis which would not yield to other treatment; but when he asked him what his guide for operating was, he said that he was unable to give any, except to state that if in any such case the patient did not get well after a certain time he made an abdominal incision, when he was almost sure to find a diseased condition of the ovaries and tubes, and what was called in this country thickening of the broad ligament. Among the other patients that he saw was the nurse whose case was described in Tait's article in the *British Medical Journal*, who before the operation suffered so greatly that she could not live out at service, and finally became an out-door pauper. Yet after the removal of her ovaries and Fallopian tubes she never had any more pain, and he had really never seen a finer specimen of a woman. On account of the better results which the English surgeons had obtained in laparotomy, as compared with American operators, he had been interested in inquiring the special reasons for this; but he found that hardly any two of them held the same views in regard to the methods of procedure. Thus, Tait, who was the most successful operator living, rejected Listerism altogether, and was simply careful to have his hands clean when he operated; but the impunity with which he opened the abdominal cavity was certainly most astonishing.

The second paper of the evening was by Dr. Henry J. Garrigues, and was on the subject:—

GASTRO-ELYTROTOMY (THOMAS'S OPERATION), COMPARED WITH OÖPHORO-HYSTERECTOMY (PORRO'S OPERATION).

In the eight cases of Thomas's operation which had been reported, he said, there had been four recoveries of the mothers, while all the children had been saved except two, who were dead at the time the operation was commenced. According to Dr. Harris's statistics, there had been eighty-four cases of the operation of Porro and its modification by Müller, with forty-seven deaths. One of the chief objections to gastro-elytrotomy was, that it was impossible to perform it with a strict observance of antiseptic methods; but he thought this could be obviated if the surgeon were thoroughly to disinfect himself, his instruments, and his patient before the operation, and to see that antiseptic measures were employed after it. Having pointed out that the number of cases was as yet far too small upon which to form any adequate basis of comparison, he took up the dangers of the two operations successively in detail, and came to the conclusion that shock had so far proved the only cause of death in Thomas's operation,

while in Porro's there was imminent danger, in addition to this, from hæmorrhage, septicæmia, and peritonitis. Among the other causes of death in cases of the latter had been tetanus, pulmonary œdema, and embolism. One advantage of Porro's operation was, that it could be performed before the cervix was dilated or dilatable (which was impossible in Thomas's); but this advantage was usually lost by the delay in operating. The former necessarily rendered the woman sterile in the future, while after gastro-elytrotomy there was a possibility of bearing other children. Whether this were an advantage or not was a question upon which medical opinion was at present divided. After speaking of the contra-indications for gastro-elytrotomy, Dr. Garrigues went on to say that in ordinary country practice he thought Cæsarean section was preferable; but if the patient were in a hospital he would select Thomas's operation if the cervix were dilated or dilatable. If this were not the case, he would perform the Porro-Müller operation. He concluded with a summary of the views expressed in the paper.

In the discussion which followed, DR. POLK was the first speaker. The place which he assigned to Thomas's operation was midway between embryotomy and Cæsarean section. It could, of course, never take the place of the latter in any case where the cervix was not dilatable or could not be reached. He then described in a detailed and graphic manner the anatomical relations, the successive steps, and the simplicity of gastro-elytrotomy, and expressed his decided preference for it in all cases were the condition of the cervix rendered it applicable.

He was followed by DR. ISAAC E. TAYLOR, DR. SKENE, of Brooklyn, who had performed Thomas's operation successfully and was enthusiastically in favor of it, and DR. LUSK, who thought that when the cervix was dilated, no other operation could be compared with Thomas's, but that when the case was seen early we needed some alternative. Porro's operation had been weighed in the balance and found wanting, and he thought the old classical Cæsarean section was preferable, especially if care were taken to use sutures in the uterus, the gaping uterine wound having been found to constitute the principal source of danger.

To this DR. GILLETTE replied that he had seen the autopsies after four Cæsarean sections, in some of which he had assisted, and in every one of the cases the uterine wound was gaping notwithstanding the fact that sutures had been carefully applied after the removal of the child. The discussion was brought to a close by the author of the paper.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, RECORDER.

THURSDAY evening, December 14, 1882. The President, DR. JAMES TYSON, in the chair.

A CASE OF MITRAL OBSTRUCTION WITH SEQUENTIAL LESIONS.

Exhibited by DR. E. P. BRUEN.

I submit this specimen because it favorably illustrates the lesion and the sequential changes in the different chambers of the heart. The auriculo-ventricular opening of the left heart is nearly occluded by an epiglottic-shaped enlargement of one of the leaflets of the mitral valve. The valve is very much thickened, and the focus of a considerable calcareous deposit. The orifice during life permitted a reflux of blood from the ventricle into the auricle. The left auricle is dilated and hypertrophied so that its cavity is about twice as large as normal. The right ventricle is very much dilated, the walls of this cavity are less than half the normal thickness, and the ventricle must have had during life twice its physiological capacity. The tricuspid valves were insufficient on account of the dilatation. The considerable enlargement of the left auricle and right ventricle occasioned during life a broadening of the area of dullness on the level of the third and fourth ribs, namely, the apex of the cardiac triangle. It also produced a decided increase in the area of the cardiac dullness to the right of the median line of the sternum. In children the heart with similar enlargement encroaches upon the left pleural cavity to such an extent that the physiological inflation of the left lung cannot occur. Bronchial breathing is produced, audible posteriorly, while anteriorly below the second interspace no respiratory murmur is audible. In these cases, when the complication of bronchitis occurs, the physical signs suggest a pleural effusion. Enlargement of the right ventricle both in children and adults causes a pronounced impulse at the epigastrium, and occasions serious pain and inconvenience. The murmur heard during life in the case from which my specimen was taken indicated this lesion, both presystolic and systolic murmurs being audible. The second sound at the pulmonary artery cartilage was also much accentuated, owing to the repletion of that vessel with blood. The first sound over the right ventricle was very clear and distinct, as is common in these cases, but the first sound at the apex was obscured by the murmur. The patient from whose body these specimens were removed was a woman, aged forty-six years, who had been subject to heart disease since twenty. The immediate cause of death was pulmonary repletion with blood, which induced right heart failure.

Compared with cases of mitral regurgitation, this mode of death illustrates a feature of the clinical pathology of mitral obstruction. In mitral regurgitation death occurs with heart failure, but usually after serious dropsy. In mitral obstruction dropsy is not so prominent a symptom, but the pulmonary engorgement prevents a perfect supply of blood to the aorta. The right ventricle failure in cases of mitral obstruction brings about death in the same manner as left ventricle failure does in cases of aortic obstruction.

PERICARDIAL EFFUSION AND ADHESION OF THE PERICARDIUM TO THE APEX OF THE HEART MISTAKEN FOR HEART RUPTURE.

Exhibited by DR. J. T. ESKRIDGE.

Dr. Eskridge said that in this case the physician making the autopsy actually considered the specimen to be one of heart rupture. The patient was an athletic young man, and perfectly well until a few days before he sought medical advice. He was under treatment for only twenty-four hours, suffering from cardiac pain and great prostration. He died suddenly and unexpectedly when no one was near him. The attending physician, who made the post-mortem examination with no professional assistance, reported effusion in both pleural cavities, the pericardium distended with thin, non-coagulated blood, and a rupture

of the left ventricle. Dr. Eskridge said that a careful examination of the heart, pericardium, adjacent glands, and portions of the larger bronchi showed marked evidences of pericarditis and pleuro-pericarditis. The pericardium was adherent to the lower third of the heart, but the adhesions were recent and easily severed. The heart was not much enlarged, its valves were nearly normal, and its muscle firm. No rupture was found. He believed that the case was one of pleurisy and pericarditis with effusion, death taking place suddenly from mechanical interference with the heart and lungs. He thought that the most plausible explanation of the doctor's mistake in calling it a case of cardiac rupture was, that when severing the blood-vessels around the heart, blood flowed into the pericardium and mingled with the serous effusion. He did not think that a firm, non-fatty heart could rupture itself by its own contractions. If the pericardium was filled with effusion, in that instance it taught a lesson of far more practical value than a case of cardiac rupture under similar circumstances would. It was evident if the pericardium should be attached to the apex of the heart in a case of pericardial effusion, in which operative interference was determined upon to free the heart's action, a thrust of the trocar into the pericardium would greatly endanger the ventricular walls.

SEVERAL SPECIMENS OF EYES ENUCLEATED ON ACCOUNT OF SYMPATHETIC IRRITATION IN THE OTHER EYE, OR FOR FEAR OF ITS DEVELOPING.

Exhibited by DR. LITTLE.

Sympathetic irritation and sympathetic ophthalmia are the only two forms of the sympathetic diseases of the eye that afford an opportunity for pathological study, and in these cases only the enucleated eye can be investigated; just what are the conditions in the eye protected by the enucleation of the other eye primarily at fault must remain uninvestigated; if full restoration of the function of vision is attained in the one sought to be protected by the enucleation of the fellow eye, great satisfaction only is felt. Less and less opportunity is being afforded of studying the condition of an eye enucleated for the presence of sympathetic ophthalmia in the other eye, since merely sympathetic irritation of the sound eye impels the surgeon to enucleate the primarily affected eye before true sympathetic ophthalmia asserts itself. The portion of the eyeball which renders liable the development of this affection when diseased is so well known that not even sympathetic *irritation* should be allowed to develop, as an early enucleation will prevent it. Enucleation of the primarily diseased eye when true sympathetic ophthalmia is present in the other eye is now questionable, as, after all inflammation has subsided under treatment, surgical procedures upon the primarily affected eye may afford the best results for visual purposes. A recent experience will bear me out in this statement: the patient refusing the advice of a former medical attendant, and also my own, after two months suddenly developed sympathetic ophthalmia of the sound eye. Enucleation was then too late, now both eyes are becoming quiet, and I am in doubt which in the end will be the more available eye. A physician recently under treatment for a severely traumatized eye has refused the advice of two surgeons, and is now doing well, but the danger of a sympathetically irritated eye is constantly before him. The pathological investigation is then mainly restricted to eyes enucleated before or after sympathetic irritation has developed in the other eye, as results show that under such circumstances full protection to the remaining eye is afforded. Investigation of eyes enucleated when sympathetic ophthalmia of the other eye is present may explain the cause of the trouble in the remaining eye, but there is so much damage done to both that our knowledge only makes us the more desirous to prevent these conditions from arising, and in the multiplicity of conditions the principal cause is lost.

When enucleation is done to forestall sympathetic irritation or ophthalmia, or when the operation is performed with sympathetic irritation just beginning or present, the eye-ball removed is in a much better state to examine and more light can be thrown on the cause of sympathetic irritation since severe inflammatory processes cloud the change from sympathetic irritation to that of sympathetic ophthalmia, and the pathological study is more difficult. My collection contains only one specimen enucleated when sympathetic ophthalmia was present, and in this case there was a double acute glaucoma with sympathetic iritis. At this time I only desire to place before you some specimens of eyes enucleated for the protection of the fellow eye from sympathetic irritation, or in which it was already beginning or developed, and where in these cases good and permanent results have been attained. Four of these cases were due to traumatism, the fifth was of an inflammatory character. All but one of the traumatic cases had the fellow eye affected, and the examination of the enucleated eye in the exceptional case justified the operation. In two cases the sound became affected shortly after the injury to the enucleated eye. In one case no irritation until forty years had elapsed since the accident to the enucleated eye. In one non-traumatic case there were repeated attacks for a series of years of irritability in the sound eye, until the pain in the diseased eye, and the disturbance of the sound eye, compelled operation. In the remaining traumatic case for twenty years the uninjured eye was unaffected, except rendering the myopia more progressive, which rendered an operation imperative for its arrest and to prevent the outbreak of sympathetic ophthalmia later in life.

The patients were aged respectively three years, forty years, forty-seven years, fifty years, and seventy years. Three of the patients were males and two females. In four cases the left eye was enucleated, in one case the right. In every case the injury or disease involved directly or indirectly the ciliary body, and where the crystalline lens remained *in situ*, or the sclerosed tissue impinged most markedly on the ciliary region, the irritation most rapidly in the other eye. Where the crystalline lens was dislocated with weakening of the sclerotic tissue no irritation appeared for forty years in the other eye. In one case with dislocation of the lens and detachment of the retina and choroid, no irritation had appeared at the end of twenty years in the other eye. In those cases where the iris became entangled in the cicatrix sympathetic irritation of the other eye developed most rapidly, in one instance the lens becoming cataractous in the sound eye, while that of the injured one was either absorbed or lost at the time of accident. In short, is it not to injury of the ciliary nerves with their varied function, and to the damage done to the tissue in which they are imbedded in the different divisions of iris, ciliary body, and choroid, that we are to look as the cause of sympathetic irritation in the fellow eye, and of these the ciliary body

and nervous structures in it, with or without involvement of the iris, as the principal part involved? When sympathetic ophthalmia arises in the sound eye, cannot it be traced to inflammatory processes added to the irritation of the ciliary nerves and involving the iris, ciliary body, and choroid. How far the retina and optic nerve participate in sympathetic irritation it is difficult to say, only we find that in enucleation for sympathetic irritation the fellow eye regains the full function of sight. In sympathetic ophthalmia, however, the involvement of the nerves and retina is a more important factor, and the fellow eye is not so likely to be restored to full function of sight, as the condition in the enucleated eye and the one affected are more serious on account of marked inflammatory processes.

Dr. Little then gave in detail the histories of his cases, but all essentials having been already given, their publication will be delayed until the next volume of the Proceedings of the Society appears.

(To be continued.)

PROCEEDINGS OF THE RHODE ISLAND MEDICAL SOCIETY.

THE usual quarterly meeting of the Rhode Island Medical Society was held in Providence, December 21, 1882, the president, DR. JOB KENYON, in the chair. Sixty-eight Fellows attended.

DR. M. FIFIELD reported a case of

FIBROID TUMOR OF THE UTERUS.

The patient is married, age thirty-nine, first menstruated at thirteen, profusely, and at intervals of two weeks until six years ago. She has had two children and no miscarriages. For six years she has had severe uterine hæmorrhage at intervals of two to five months. She is anæmic. Health failing. The uterine tumor has grown steadily, and now extends above the umbilicus. What is the best treatment for such a case? Would Battey's operation afford relief?

DR. WEAVER reported that the patient on whom Dr. Tyng performed Battey's operation in Providence, January 8, 1880, for the relief of exhausting menorrhagia and uterine fibroid had entirely recovered her health. The fibroid gradually diminished in size, and cannot now be recognized.

The PRESIDENT reported a case of uterine fibroid tumor discovered ten years ago. Since the menopause the tumor has dwindled away, and now causes no trouble. If the patient is losing strength it is doubtless justifiable surgery to hasten the menopause by removing the ovaries.

DR. J. HOWARD MORGAN reported a case of

ANEURISM OF THE DESCENDING AORTA.

R. S., age thirty-eight, stone-cutter, native of Scotland, was seen April 19, 1882, in Westerly, having a few days before arrived from Vancouver Island. He was emaciated, lying on the left side, knees drawn up and back arched, countenance drawn and pinched, and occasionally distorted by sharp neuralgic pains. These pains, following the course of the right sciatic nerve, had tortured him almost constantly for over twelve months.

A prominence of the vertebral spines in the lower dorsal region had existed for some fifteen months, with no marked tenderness. Auscultation and percussion of the chest gave only negative results.

It was proposed to apply a plaster jacket in the hope of relieving his sufferings and enabling him to move about more freely, but owing to the patient's exhausted condition and the dread of causing pain this measure was, perhaps fortunately, never attempted. Death occurred suddenly on May 18th, and at the post-mortem examination an aneurismal sac was found on the right side of the spinal column, extending from one centimetre above the nipple to a point opposite the crest of the ilium. The sac was very thin at the upper portion, and had ruptured into the right pleural cavity. Pressure of the aneurism had caused absorption of the bodies of the dorsal vertebræ from the fifth to the twelfth inclusive. Opposite the sixth dorsal vertebra the sac communicated with the aorta by a small opening admitting only the tip of a finger. This small passageway and the pedunculated form of the sac probably accounted for the absence of auscultatory signs.

DR. F. B. FULLER reported a case of

CARCINOMA FOLLOWING ORCHITIS.

The patient, aged thirty-four, had chronic orchitis for twenty-two years caused by a blow on the testis when a lad of twelve years. Four months before removal the tumor became painful and rapidly increased in size, adding one third to its bulk in four months.

Testicle removed February 10, 1882. Excellent recovery from the operation, and immediate recurrence in the abdominal cavity, forming a tumor the size of a man's head, and causing death in two months.

Character of the Growth. Upper two thirds of the tumor is fibrous, and contains cysts and enchondromatous masses. Lower third is encephaloid. The abdominal tumor was encephaloid.

DR. W. H. PALMER read a paper on

THE OFFICE AND DUTY OF CORONERS.

Regarding the present Rhode Island law concerning the coroner and coroner's jury, the essay claimed "this system at its best is prompt, economical, and impartial. Beyond any other mode of preliminary examination it secures deliberation in suspicion and information in accusation. The condition is that we shall have it at its best. Such defects as are charged against it are not inherent in the system but in the incapable administration of the system." The office of coroner should always be filled by a medical man. Dr. Palmer is not in sympathy with a growing public sentiment which desires the abolition of the cumbrous coroner's office and the substitution of a system in which medical men shall simply determine the cause of death, leaving an inquest, if necessary, to be held by another official.

DR. ARIEL BALLOU called attention to the great importance, under the present system, of having only medical men for coroners.

DR. CASWELL was surprised that any but physicians had been appointed coroners in Providence. He defended the system of medical examiners as established in Massachusetts, and claimed that the system works admirably.

DR. O'LEARY inquired whether a coroner under the present system is expected to determine only the proximal cause of death, or to investigate remote and contributive causes.

DR. PALMER, in reply, quoted the recent Calender disaster in Providence as a case in which the coroner's investigation includes a rigid examination of the surroundings, such as the industries carried on in the building, the chemicals and materials used, the width and construction of stairways, exits, and fire-escapes, the condition of streets leading to the building, etc.

DR. R. F. NOYES read a paper on

PERITYPHLITIS.

The operation for perityphlitic abscess is of American origin, and Dr. Willard Parker was the operator. Dr. Hancock, of London, who operated in 1848 and reported his case the same year,[1] is often awarded priority by surgical writers, but Dr. Parker's operation was done in 1843, although not reported until 1867.[2]

In 1872 Dr. Bull analyzed sixty-seven cases of perityphlitic abscess treated without operation. Of these there were thirty-three deaths, a mortality of nearly fifty per cent.

Dr. Noyes had collected one hundred reported cases treated by operation. Of this number there were fifteen deaths, eighty-four complete recoveries, and one recovery with fæcal fistula.

Of these one hundred cases a foreign body or fæcal masses were lodged in the abscess cavity in thirty-one instances. The advantages of the knife over the aspirator in treating this class of cases are obvious, though the aspirator is valuable in diagnosis.

DR. ARIEL BALLOU reported a case of perityphlitic abscess which discharged into the colon. The appendix vermiformis sloughed off, and was voided per anum. The patient eventually recovered.

DR. D. O. KING reported a case of perityphlitic abscess in a child aged four and a half years, which Dr. Noyes saw in consultation. An incision was made through the abdominal walls, about two inches in length, just above and parallel to Poupart's ligament, and a warm carbolized dressing applied. The child made a good recovery.

DR. W. SHAW BOWEN reported in detail a case of

SECONDARY LARYNGEAL LUPOID ULCERATION.

Mr. H., aged thirty-nine, of regular habits, fell down a flight of stairs six years ago, causing fracture of the nasal bones and a displacement of the vomer. He recovered with but little deformity. In a few months a hard pimple appeared on the lip near the left ala nasi, which finally broke down and formed a ragged-edged ulcer. The ulceration extended upwards, involved the mucous membrane of the nasal cavity, and progressed until the vomer and portions of the turbinated bones were destroyed, and the superior and middle pharyngeal regions had undergone extensive morbid changes. Recovery seems to have been spontaneous, as nothing in the way of scientific medical treatment was undertaken.

The voice was somewhat muffled, but the patient was able to sing in a low register without great fatigue.

In December, 1881, he noticed a slight soreness of the throat, with increased vocal huskiness. The sore throat became constant, deglutition difficult, and in three months after the first signs of dysphagia he was unable to swallow solid food. A troublesome cough and loss of weight led the attending physician to pronounce the case one of laryngeal phthisis. It was then that Dr. Bowen saw the case. The uvula and free edges of the faucial pillars were then destroyed; the superior pharynx closed by union of the palatal arches with the posterior pharyngeal walls, and communication with the post-nasal space was by a small circular orifice. The epiglottis was partially destroyed, and the laryngeal mucous membrane so swollen and thickened that it was difficult to obtain but a faint glimpse of the cords.

Antisyphilitic treatment was tried for three weeks, as the diagnosis between laryngeal lupus and syphilitic lesions is always difficult.

Morphine mixed with finely powdered starch was insufflated over the surface of the epiglottis and on the laryngeal ulcers daily, and the patient instructed to apply olive oil containing a small amount of iodine to the base of the tongue and the surface of the epiglottis just before attempting to swallow food.

The diagnosis of scrofulide lupus was reached after abandoning the antisyphilitic treatment.

A four hundred and eighty grain solution of silver nitrate was carefully brushed over the ulcerated surfaces. Nearly twenty such applications were made before a slight change was apparent. A more rapid improvement followed the use of a mixture of iodoform in olive oil.

DR. E. T. CASWELL reported two recent cases of

LITHOLAPAXY.

The first case was that of a man, aged sixty-two, from whom ninety-two grains were removed. Second case, a man aged forty-seven; weight of calculi thirty-one grains, ten grains being the weight of a round button-shaped calculus that lodged in the tube, and was thus extracted.

Dr. Caswell exhibited and explained the latest modification of Dr. Bigelow's evacuating apparatus.

DR. W. E. ANTHONY read an appreciative obituary notice of the late Dr. George Capron.

DELEGATES TO STATE MEDICAL SOCIETIES.

The President appointed delegates to State medical societies for 1883 as follows: —

Maine: Drs. W. S. Bowen and W. E. Anthony.
New Hampshire: Drs. A. Ballou and W. R. White.
Vermont: Drs. O. C. Wiggin and A. O. Robbins.
Massachusetts: Drs. H. G. Miller and G. T. Swarts.
Connecticut: Drs. A. G. Browning and C. O'Leary.
New York: Drs. J. W. C. Ely and W. O. Brown.
New Jersey: Drs. O. Bullock and N. O'D. Parks.

— The fifteenth edition of the United States Dispensatory will be ready in January, 1883. The editors are Dr. H. C. Wood, Professor of Materia Medica and Therapeutics in the University of Pennsylvania, Joseph P. Remington, Professor of Pharmacy, and Samuel P. Sadtler, Professor of Chemistry, in the College of Pharmacy of Philadelphia. The revision has occupied about three years, and is said to be in all respects most thorough and complete. The encyclopædic character of the Dispensatory is developed to the greatest extent. The new Pharmacopœia will be in all its parts fully expounded and discussed, and the most recent non-officinal medicines, as well as those long out of date, will be carefully considered in the second part of the work.

Medical and Surgical Journal.

THURSDAY, JANUARY 4, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

1883.

THE JOURNAL wishes its readers and contributors a happy new year.

Hope springs eternal in the human breast, and nothing marks that eternal cheerfulness more decidedly than the time-honored custom of wishing all good things to friends and acquaintances at each recurrence of a new year.

To wish a doctor a prosperous year will, it is to be hoped, not be construed by any one as wishing corresponding ill to the rest of mankind; on the contrary, we trust that each and every one of our medical readers may be the minister of good and the avertor of evil to his circle of patients, and find his pleasure and his profit in so doing, and that each recurring week may find him in condition to enjoy and profit by the good things that his JOURNAL brings.

LEPROSY. A CASE IN SALEM, MASSACHUSETTS.

THE neighboring city of Salem, the old rival of Boston in commerce with distant lands, has reasserted her claim to her old preëminence by becoming possessed of a case of advanced leprosy, of the genuineness of which there seems to be no question. The subject, a former citizen of the town, contracted the disease in the Sandwich Islands, from whence he escaped to San Francisco, to avoid being transferred to Molokai, the leper colony of those islands, and poverty and the malady finally drove him back to his old home, where the city authorities have been somewhat exercised as to the ultimate disposition to be made of this unusual importation. We believe this may be considered the only known example of true leprosy at present in this part of the country, though not long since a case was under Dr. J. C. White's treatment at the Massachusetts Hospital, another was formerly known in Boston, and a third case was discovered about a year ago in Providence. These three cases had all escaped from the lazaretto at Tracadie in New Brunswick.

The bacillus of leprosy was discovered in 1874 by Armauer Hansen, physician in charge of the hospital for lepers at Bergen, Norway. In communicating to the Christiania Medical Society in that year the results of his inquiries into the ætiology of leprosy, he announced that he had frequently observed small rod-shaped bodies in the leprous tubercles, and that these could always be found by careful search, though it has since been shown that their detection is by no means always equally easy at all stages of the disease, the bacilli being found more especially in fully developed tubercles rather than in those which have entered on the atrophic stage. Dr. Hansen's discovery has been confirmed by numerous investigators, among whom we may mention Cornil and Suchard in France, Hewsen and Köbner in Berlin, Majocchi and Pellizzari, in Italy, and Neisser, Eklund, Hillairet, and Gaucher and Berman in this country. The bacilli have been found in the blood, but their mode of entrance into that fluid is unexplained; they are found in the discharges from leprous sores but not in the skin.

With our present knowledge it is easy to consider leprosy as contagious in the sense of being inoculable, and to understand why, being contagious probably in that sense only, it does not spread more generally and rapidly. When he has reached the inoculable stage the leper, as a rule, has become an object of aversion.

Late years have added some important contributions to the literature of leprosy, and the question of its contagiousness has been a good deal discussed, with a manifest recent tendency to return to the old Biblical belief that it is contagious, at least to a certain degree. This question the discovery and present knowledge of the bacillus of leprosy should go far towards setting at rest, especially if still more thoroughly confirmed. Of these recent contributions to our knowledge of the disease, the Report on Leprosy to the Royal College of Physicians, the Report of the State Board of the Sandwich Islands, containing the observations of Dr. N. B. Emerson, and the studies of Mr. Fletcher at Cape Breton, published by Dr. McPhedran,[1] are perhaps the most important.

Dr. J. C. White, in a paper on Contagion in Leprosy, read at the last meeting of the American Dermatological Association,[2] gives a carefully prepared and thorough statement of the facts and arguments bearing on the question of contagion. In regard to the ætiology of leprosy he says: —

"The origin of the disease is unknown, it is too remote for investigation.

"There has been no apparent change in its type since the earliest intelligible records, either in relation to chronological or geographical distribution.

"It has ravaged countries where it is now wholly absent, although it still survives about the outskirts of some of them.

"It is endemic at present over large parts of the earth's surface, and prevails under the most diverse conditions of climate, soil, altitude, temperature, ethnic stock, and customs.

"Such diversity is a satisfactory demonstration that these extraneous conditions may possibly affect the predisposition to or course of the disease in individual or nation, that their ætiological relations cannot be causative.

"It is most prevalent among peoples not on the highest planes of hygiene or morals.

"It occurs notably in families through several generations, it is claimed, although it fails in great proportion to affect the immediate descendants of lepers. It also affects great numbers of persons residing permanently or temporarily in leprous regions whose ancestry is free from the disease.

"It occurs occasionally in sporadic form, that is, in persons who have never visited infected regions.

"The period of incubation is without definitely known limits. It rarely appears in children below the age of five. The shortest time of development after residence in an infected region is

[1] Canadian Journal of Medical Sciences, September, 1881.
[2] American Journal of Medical Sciences, October, 1882.

one year. It has appeared as late as fourteen years after such residence or recognized contact with lepers.

"The question in ætiology which I propose to discuss has been satisfactorily settled apparently more than once, although in contradictory ways, and so conclusively in modern times in the general opinion of the medical profession that until within a year or two any attempt to reopen it would have appeared almost ridiculous. Some peculiar events in its history of late occurrence, however, would seem to make this not only a legitimate agitation at present, but imperative in the interests of science and national economy."

Dr. White discusses the disease especially as observed of late in the Hawaiian Islands, Cape Breton, New Brunswick, and various parts of the United States. He is a strong advocate of isolation, feeling that lepers belong to the dangerous classes of the community which require perpetual confinement, and the sooner this remedy is applied, the less seeming cruelty will attach to it. In regard to the United States he says: —

"We have at present an unknown number of lepers in the United States, — let us say fifty or a hundred; one centre in Louisiana, another in Minnesota, Wisconsin, and Nebraska, another in California and Oregon, affecting three entirely distinct nationalities, in different climates, and under quite diverse methods of living. It is evident that the disease may make more rapid advance in one part than in another. Any circumstance, for instance, which tends to soften or abrade nodules, as a hot climate possibly, would of course greatly increase the danger of infection, so that the necessity of interference by compulsory means might be more urgent in the former than in the latter. It is evident, however, that such measures should be undertaken by the national government, and that they should be made applicable to all parts of the country alike. We have a National Board of Health to which their execution might be intrusted. There can be little doubt of their necessity, or of their success in eventually exterminating the disease. When this necessity becomes more apparent this result will be immensely more difficult of accomplishment. These measures should be: the establishment of graded hospitals in possibly insular localities in various parts of the country, to which all access should be prevented excepting under restrictions determined by professional rules; the enactment of laws which should make residence compulsory and perpetual, and the concealment of the disease punishable by severe penalties. These rules should apply to so-called sporadic as well as to endemic and imported cases, but the latter might be given the option of returning to their native land. The immigration of lepers should be prohibited and arrested at ports of arrival by inspection so far as possible, as other contagious diseases now are by quarantine regulations. By the establishment of such national measures immigration from leprous countries would largely cease, lepers would no longer change their residence within the country to escape the action of local laws against their liberty, marriage with them would become abhorrent when the people had thus become aware of its dangers, and after a generation has passed the disease would be virtually eradicated."

SIR THOMAS WATSON, M. D., F. R. S.

A MAN like the late Sir Thomas Watson belongs to science, to the art which he practiced, and to the profession which he adorned; moreover, the language which he knew how to use so well is ours, hence it is at once our duty and our pleasure to do honor to his memory. His death, in his ninety-first year, was announced by telegraph, December 12th, and, since the paralytic attack which manifested itself October 22d last, had not been unexpected. Some account of this attack and of the subsequent illness were given in a letter from London, published in the JOURNAL November 30th. Further details of the closing scenes, and of Sir Thomas's long, active, and useful life, have but lately reached us.

If we recall that Sir Thomas Watson was born as long ago as 1792, and was in the active exercise of his profession until within ten or twelve years, we realize somewhat all that such a life has witnessed and represents in changes, in experience, in progress.

He was born at Kentisbeare, a small village in Devonshire, where his father was temporarily residing, and was descended from an old Northumbrian family. He received his early education at the Bury St. Edmund's Grammar School. He entered St. John's College, Cambridge, in 1812, taking his B. A. degree in 1815, and being classed as tenth wrangler. In 1816 he was elected a fellow of St. John's College, and commenced the study of medicine at St. Bartholomew's Hospital in 1819, when twenty-seven years old. He passed one session at Edinburgh, and received a practicing license from Cambridge in 1822; in 1823 he was made a proctor of the university, and graduated as Doctor of Medicine in 1825, about six years being thus spent upon preparatory medical studies, and the age of thirty-three years being reached before taking the final degree. In 1826 he was admitted a Fellow of the Royal College of Physicians of London, to which body he was Lecturer on Materia Medica in 1833, 1834, and 1835, becoming its President and an F. R. S. in 1862. In 1827 he was appointed physician to Middlesex Hospital, and the following year to King's College Hospital, where, until 1836, he held the office of Professor of Forensic Medicine, in this year being appointed Lecturer upon the Principles and Practice of Medicine. He then began the course of lectures which ultimately expanded into the two volumes of Principles and Practice of Physic, so well known to us all who use the English language.

These lectures, their author tells us, were put together with unavoidable haste during the medical session in which they were first delivered, and were repeated, with slight modifications, during four successive years; they were afterwards printed in the pages of the *Medical Gazette*, and were first published in book form in 1843. In the paucity of good text-books on the subject in English at that time these volumes met a want which was strongly felt. The simplicity, clearness, and charm of the style in which the author's great clinical experience and sound and extensive learning found utterance, made Watson's Practice at once immensely popular, and that not merely among professional readers. It passed rapidly through five editions in England, and several in this country. The publisher, we happen to know, was so astonished and unnerved at the demand for the work, that when he called to make the first payment on account of the edition, he presented the author with a cheque for two thirds of the profits instead of for one half, as had been originally agreed.

The conspicuous attention devoted to the chapter on Different Modes of Dying and the Causes of Sudden Death was inspired, it is thought, by the fact that the writer's wife died most suddenly a few days after her confinement, in his own presence, the cause of death being at that time unexplained, but subsequently recognized as due to pulmonary thrombosis.

Sir Thomas Watson resigned his chair at King's College in 1840. He was appointed Physician Extraordinary to the Queen in 1859, Physician in Ordinary in 1870, and in 1866 a Baronetcy was conferred upon him, the degrees of D. C. L. and LL. D. having been bestowed by the universities of Oxford and Cambridge respectively in 1862.

He was called, together with Sir William Jenner and Sir Henry Holland, to attend the Prince Consort in his last illness, and also in the fatal illnesses of the Duke of Cambridge and the Princess Mary.

He was a man of exemplary piety and strong religious beliefs, but broad and liberal in his dealings with mankind, with a well-stored and well-balanced mind, and was greatly beloved and trusted by all classes. He had a very high ideal of the usefulness and dignity of the profession to which he devoted himself, and whilst living up to it in his daily walk of life bore his frequent honors with modesty and simplicity. Notwithstanding his advanced age, his mind was quite clear up to the beginning of his final illness, which overtook him at the house of his son in Reigate. In death as in life he was fortunate in being surrounded by family and friends who loved and admired him.

THE ARMY MEDICAL MUSEUM AND LIBRARY OF THE SURGEON-GENERAL'S OFFICE AT WASHINGTON.

THE following address to the Rhode Island congressional delegation was very numerously signed at the last quarterly meeting of the State Medical Society: —

"We, the undersigned, physicians and surgeons of Providence and the State of Rhode Island, respectfully urge upon our senators and representatives the importance of providing a commodious fire-proof building for the Army Medical Museum and Library of the Surgeon-General's Office in Washington, with the least possible delay. This museum and library are the most valuable of their kind in the world, and the medical profession of this country take a deep interest in their preservation and progress. We would respectfully but strongly protest against any action which should separate the library from the museum or remove it from its present management. And we hope that the necessary authority will be promptly given for the completion of the Index Catalogue, a work of the greatest value to all medical men, and of which we, as American physicians, are justly proud."

This is a very proper subject for physicians to take an interest in, and in regard to which to bring their influence to bear upon representatives in Congress. There can be no two views as to the importance of placing such valuable and unequaled collections as those of the Army Medical Museum and of the Library of the Surgeon-General's Office at Washington in a suitable and commodious fire-proof building. There may possibly be differences of opinion, though we think not among medical men, as to the propriety of uniting the Library of the Surgeon-General's Office with the general Congressional Library, and placing the whole under one management.

Such a change is advocated in some quarters, and commends itself especially, we believe, to the librarian in charge of the Congressional Library. We certainly hope it will not be made, but that books and specimens may be housed as they should be without being separated, and when both have been made safe as well as more accessible, the Index Catalogue of the library may not remain perforce unfinished from lack of the needed appropriations. We are sorry to see that the House Committee on Appropriations has reduced the appropriation for these two objects from $10.000 to $5,000. The Chairman, Mr. Butterworth of Ohio, seems for some reason ill disposed. It is to be hoped that better judgment or less ill will may be encountered in the Senate.

SUPPLEMENTARY REPORT OF HEALTH DEPARTMENT OF MASSACHUSETTS BOARD OF HEALTH, LUNACY, AND CHARITY.

IN a short editorial, December 14th, on Changes in the Massachusetts Board of Health, Lunacy, and Charity, we called attention to the fact that "with some excellent papers now on hand ready for publication the annual Supplementary Reports of the Health Department have been quietly allowed to come to an end." No such Supplementary Report has been published since that for 1880, and we now beg to call the attention of the members of the Board and of our readers to the following extract from Chapter IV., Section 8 of the Revised Statutes of this State: —

"There shall be printed annually on or before the assembling of the General Court, or as soon thereafter as possible, the number of copies of documents and reports specified in the following list: —

"Report of State Board of Health, Lunacy, and Charity, two thousand copies.

"Supplementary Report of the Health Department of the same, four thousand, five hundred copies."

DIPLOMA-TIZATION.

OUR language is constantly enriched by new words, which owe their existence to the exigencies arising from new discoveries in the arts and sciences, and from the establishment of new industries. The new industry established in this State seems to call for a word to express it concisely, and we have ventured to put in capitals at the head of this article a word which we feel sure will meet the approval of careful linguists as well as those interested in the new production. It is in strict analogy with such words as civilization: the hyphen has been introduced simply as a means of showing its derivation, and will undoubtedly drop out as the word becomes familiar. It is, of course, intended to express the process by which a community gradually becomes converted to the state of being universally diploma'd.

The JOURNAL takes pride in keeping its readers informed as to progress in various branches closely connected with medicine, and to that end publishes at intervals reports on progress in the various departments. It has under advisement the addition of a Report on Progress in Diplomacy and Diplomatization, but there is some difficulty in finding a reporter. It was at first suggested that the Commissioner of Corporations or some one in his office should be in-

vited to furnish the report, but a moment's reflection was sufficient to show that no one connected with the business of incorporation would have either time or strength left for outside duties.

We have to record the fact that

"the First Medical College of the American Health Society, having its location in Boston, has taken a charter for the purposes of preventing disease and pain; promoting physical perfection; uniting the interests of patients and physicians; establishing a medical school, college, or university; and diffusing valuable knowledge of physical beings. C. W. Hodgdon is its president, and L. D. Hawkins treasurer, George Dutton secretary, Edwin V. Wright, Warren H. Sherman, Albion Knowlton, Josephine R. Stone, and Lucy A. Cooke, trustees."

In regard to the American University, a daily contemporary of December 28th is responsible for the following: —

THE AMERICAN UNIVERSITY.

Dr. Joseph Rodes Buchanan, author of System of Anthropology and other works, is to be the head of this pantological institution, to be located in Boston, one department of which, the medical, is to be opened in April next. The object of this movement is to realize the highest ethical principles in education, as well as to impart thorough instruction in technical knowledge. For example, that the medical art may be made philosophic and satisfactory to a rational mind will be demonstrated, it is anticipated, by this branch of the university. A charter for the American University, to be established in this city, was issued a few days since. The university will pay as much attention to moral as to intellectual culture, and will make industrial occupation a part of education. The endowment pledged to the university will insure the operations of the institution when a suitable corps of professors is obtained.

MEDICAL NOTES.

— Dr. Henry I. Bowditch, in a communication to *The Sanitarian*, recommends that the Surgeon-General of the United States Army be *ex officio* a member of the National Board of Health, and have a seat in the Cabinet. He also suggests that a Department of Public Health is as important, and will soon be so recognized, as any other Department of the National Administration, and that when the time comes for its establishment, the Surgeon-General should act as secretary of it.

— The New York Post-Graduate Medical School has thus far met with gratifying success. The second term opens on January 8, 1883, and continues until April 28th without intermission. It is hoped that with its enlarged accommodations, improved facilities for instruction, and increased corps of teachers, it will meet with still greater success.

NEW YORK.

— St. Mary's Hospital, a new Roman Catholic institution, on St. Mark's Avenue, Brooklyn, was formally opened for the reception of patients on the 17th of December. Addresses were made on the occasion by Mayor Low and Bishop Loughlin, and the latter, in the course of his remarks, said that no distinction of race, creed, or country was to be made in the hospital. The building is of brick, with facings of Nova Scotia sandstone, and is four stories high. Together with the grounds, which comprise altogether sixty-one city lots, it has cost about $250,000. This is only one half the size of the building as it will be when finally completed, but there are accommodations for four hundred patients at present. The medical staff is made up of some of the best known Brooklyn practitioners, with Dr. John Byrne at its head.

— The opening of the new Eastern District Dispensary and Hospital, on South Third Street, Brooklyn, East District, took place on the following day. Mr. Demas Strong, president of the board of trustees, presided, and addresses were delivered by the mayor and Judge Neilson. The hospital is intended for surgical cases, and will accommodate forty beds. The land and building cost $45,000, which has been raised entirely by private subscriptions.

— The necessity of establishing a hospital in New York for children suffering from contagious diseases was discussed by the Commissioners of the Sinking Fund at a meeting held December 15th, when President Chandler and Dr. Woolsey Johnson, of the Board of Health, Dr. Abram Jacobi and Mr. Elbridge T. Gerry, president of the Society for the Prevention of Cruelty to Children appeared, and made addresses in favor of its establishment at the foot of East Sixteenth Street. Dr. Chandler said that during 1881 there were 7338 cases of scarlet fever among children, of which 1964 proved fatal, while of 5272 cases of diphtheria reported, 2249 died. There were in all, during last year, 19,157 cases of contagious diseases among children reported, of which 6160 proved fatal. Mr. Gerry stated that recently his Society removed from the Infant Asylum on University Place over eighty children with scarlet fever, diphtheria, and whooping-cough. The Board of Health were not able to do anything, the reception hospital being the only place for the care of such cases, while the buildings on Blackwell's Island were over-crowded with cases of small-pox, typhus, and typhoid fever.

PHILADELPHIA.

— It is intended to establish this coming spring an institution for Post-Graduate Instruction in which lectures may be attended upon special subjects under the charge of certain leading men in the profession in Philadelphia. Application is now making for the charter to the legislature, and it will probably soon be obtained. The names of those connected with this project are withheld for the present, but we have learned of some, and they are such as to need no guarantee of the success of the experiment.

— A dinner to Prof. Austin Flint, of New York, will be given on the completion of his course of lectures before the County Medical Society. The date has not been determined on, but it will probably be January 15, 1883. It is expected to be a very grand affair, as may be inferred from the names of the committee having the affair in charge, composed of Drs. Alfred Stillé, Chairman, J. M. DaCosta, William Pepper, S. W. Gross, James Tyson, Horace Y. Evans, and J. Ewing Mears, Secretary.

— The death of Dr. George Fox, of this city, has been announced, occurring December 27th. He had for some years led a retired life, and had relinquished active practice, although he continued his membership of the College of Physicians and other scientific societies. He was graduated in 1828 from the University of Pennsylvania, and then entered Pennsylvania

Hospital as resident physician, in which position he served until 1830. In 1848 he was elected attending surgeon to the hospital, and in 1854 resigned after six years' faithful service. His achievements as a surgeon belong to a past generation, but his apparatus for fractured clavicle had a great reputation for many years as a substitute for Desault's dressing, and is still in use, in modified form, at the Pennsylvania Hospital.

ST. LOUIS.

— The Board of Health of St. Louis has just finished an examination of the St. Louis Eclectic Medical College, of which Dr. George H. Field is Dean. The investigation arose out of the refusal of the Board of Health to register its graduates and to grant the college the privileges of the city hospitals. It is claimed by the Health Officers that the college is not in good standing with the profession, having been expelled from the National Eclectic Medical Association and the State Association; that its graduates are not recognized by any board of health in the country; that the standing of its faculty, one of whom had been charged in the courts with abortion, is bad, and that the college sold diplomas without requiring attendance on lectures. These charges were not refuted, and the Board unanimously voted to sustain Health Commissioner Francis in his non-recognition of the school.

Correspondence.

LETTER FROM LONDON.

MR. EDITOR, — The funeral of Sir Thomas Watson at Reigate was conducted in strict accordance with the spirit of true humility which was one of the most marked features of his character. He had expressed, in terms so strong as to be almost a command, the desire that his funeral should be conducted without pomp or useless parade, and his surviving relatives lovingly respected the behest. Accordingly, the remains of the deceased baronet were placed in a plain coffin of polished oak, decorated only with the beautiful floral offerings of affectionate friends and an inscription recording his name, the year of his nativity, — 1792, — and the date of his death — December 11, 1882. At half-past two the coffin was brought forth from the house and placed on a bier, on which it was taken to the place of interment, followed by the immediate relatives, among whom were the eldest son of the deceased and the inheritor of the baronetcy — Sir Arthur Watson, Lady Watson, Miss Watson, Miss Mabel Watson, Miss Amy Watson, Captain Watson, Master Gordon Watson, and friends and some representatives of the profession which the deceased for more than half a century had served and adorned. The *cortège* passed slowly through the private grounds of Reigate Lodge, into the main road, along which it continued for a few hundred yards, until it reached the gates of the churchyard. Here the body was met by the clergy and a surpliced choir, who chanted the opening sentences of the ritual. The greater portion of the service was, as usual, read within the church itself, a building venerable with age, and interesting as the burial place of Admiral Lord Howard, of Effingham, of Armada fame. Two well-known hymns were sung by the choir and congregation, and afterwards there was a procession to the adjoining cemetery, where the remains were interred in an ordinary grave, the bare earth of which was hidden by evergreens and flowers. A few of the townspeople were present, but not a sufficient number to deprive the obsequies of the private character it was designed they should possess. Nature shrouded the little band of mourners in an almost impenetrable mist, which intensified the general sadness, and invested the most picturesque of country churchyards with an unwonted aspect of desolation.

A more representative than numerous attendance of medical men paid the last token of respect to the memory of this most beloved leader of the healing art. The season of the year, and the severity of the fog in London, prevented many of the senior members of the profession from attending the funeral, no public announcement of which was made before the issue of the *Times* on the morning of the funeral. The President of the College of Physicians, Sir William Jenner, M. D., Bart., was prevented from attending by a summons to her majesty; but the College was represented by several of its Senior Fellows, among whom Drs. John Ogle and Sieveking were noticed. There were present also Mr. Spencer Wells, the President of the College of Surgeons, Dr. Pitman, a member of the Council of King's College, some members of the staff of King's College Hospital, including Professors George Johnson and Joseph Lister; the last two named, who had attended the deceased in his recent illness, led the column of medical and surgical mourners. Conspicuous among these was the snowy head of that venerable and almost patriarchal representative of the Army Medical Service, Dr. Jackson. Illustrative of the characteristic thoughtfulness and unselfishness of the deceased, it was mentioned that in his last illness he kept his bed before he was compelled to do so, as he said that by so doing he would spare others the inconvenience that they might experience if he did not die in his bed.

LONDON, *December* 16, 1882.

Miscellany.

A RECEPTION TO DRS. HOLMES AND BIGELOW.

A RECEPTION was given last Thursday evening to the retiring Professors of the Harvard Medical School, Dr. Oliver Wendell Holmes and Dr. Henry J. Bigelow, by Dr. C. B. Porter at his house in Arlington Street in this city. A large number of invitations were sent out not only to members of the profession in Boston but to distinguished physicians in other cities. His Excellency the Governor, his Honor the Mayor, the President of Harvard University, and other dignitaries and prominent citizens were present to do honor to Drs. Bigelow and Holmes. It was altogether a notable gathering and a very enjoyable occasion.

DISINFECTION IN TYPHOID FEVER.

As an evidence of the importance which is attached to careful disinfection in typhoid fever, which was advocated in a recent meeting of the Clinical Section of the Suffolk District Medical Society, the following official copy of the recent action of the "Con-

seil d'Hygiene et de Salubrité du Département de la Seine" is worthy of notice. The ordinance has been published, and copies are sent to every householder in any infected quarter.

"When a patient is found to be suffering with typhoid fever it is important to observe the following hygienic cautions: —

"I. *Isolation.* The patient should be placed in an apartment by himself and isolated as completely as possible from the other members of the family. If the circumstances do not permit a satisfactory isolation, it is preferable that the patient be taken to a hospital. If the patient remains at home, only those persons who are intrusted with his immediate care should be permitted to enter the sick-room. Children and young persons should especially be excluded from entrance of or communication with the rooms pertaining to the patient. The nurses and others in attendance upon the patient are advised to bathe in phenylated water (10 grammes to one liter water).

"II. *Ventilation of the Sick-Room.* The sick-room should be frequently aired and ventilated. All draperies, hangings, and carpets should be removed. The bed should be placed in the centre of the chamber if possible.

"III. *Disinfection of the Dejections.* The dejections of the patient, before being carried from the chamber to the water closet or vault, should be disinfected according to their volume by means of a solution of chloride of zinc (50 grammes to one liter of water). The same solution should also be poured into the vault or water-closet whenever the dejections of fever patients are deposited there.

"IV. *Disinfection of the Clothes, Bedding, etc.* All clothing of the body, the bed linen, and every article used in the care of the patient, should at once be plunged in a solution of phenic acid (20 grammes to the litre water) as soon as they are removed from the chamber, and should then be immediately sent to the laundry.

"V. *Fumigation of the Chamber.* Upon the recovery of the patient, or upon his death, a pan of ignited charcoal, resting in a pan of sand, should be placed in the room, upon which coarsely broken sulphur should be laid (20 grammes to the cubic metre), and the room should be tightly closed for twenty-four hours. In the mean time the clothing and bed linen should be washed with the greatest care. The furniture, floor, fixtures, etc., of the room should be washed with phenylated water (20 grammes to the litre). The room should not be refurnished or occupied for seven days after the fumigation."

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 23, 1882.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2975: under five years of age 1029: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 599, consumption 421, lung diseases 419, diphtheria and croup 230, scarlet fever 81, typhoid fever 78, small-pox 77, diarrhœal diseases 39, malarial fevers 30, measles 15, whooping-cough 15, cerebro-spinal meningitis 14, puerperal fever 12, erysipelas eight. From *small-pox*, Baltimore 57, New Orleans 13, Chicago four, Philadelphia two, Pittsburg one. From *diarrhœal diseases*, New York 11, St. Louis and Cincinnati four each, Fall River and Somerville three each, Boston and Pittsburg two each, Brooklyn, Chicago, Baltimore, District of Columbia, Providence, New Haven, Charleston, Nashville, Lynn, and Holyoke one each. From *malarial fevers*, New Orleans 11, New York seven, Brooklyn five, Chicago, St. Louis, Baltimore, Cincinnati, District of Columbia, Nashville, and Holyoke one each. From *measles*, New York nine, Boston and New Haven two each, Pittsburg one. From *whooping-cough*, New York eight, Philadelphia three, Cincinnati two, Chicago and Pittsburg one each. From *cerebro-spinal meningitis*, Chicago four, St. Louis three, Baltimore and Nantucket two each, New Haven, Somerville, and Haverhill one each. From *puerperal fever*, Chicago three, New York and Providence two each, Boston, St. Louis, District of Columbia, Buffalo, and Fall River one each. From *erysipelas*, Chicago three, Buffalo two, New York, Brooklyn, and St. Louis one each.

Five cases of small-pox were reported in Cincinnati, Pittsburg two; diphtheria 51, scarlet fever 27, typhoid fever 19, in Boston; scarlet fever 14, and diphtheria six, in Milwaukee.

In 33 cities and towns of Massachusetts, with a population of 965,151 (population of the State 1,783,086), the total death-rate for the week was 20.75 against 20.78 and 20.63, for the previous two weeks.

For the week ending December 2d, in 170 German cities and towns, with an estimated population of 8,464,027, the death-rate was 23.1. Deaths reported 3767: under five years of age 1702, consumption 495, lung diseases 378, diphtheria and croup 208, diarrhœal diseases 144, scarlet fever 102, typhoid fever 54, measles and rötheln 61, whooping-cough 42, puerperal fever 17, small-pox (Bromberg and Koblenz one each) two. The death-rates ranged from 12.3 in Darmstadt to 33.1 in Duisburg; Königsberg 26.6; Breslau 26.1; Munich 26.7; Dresden 23.6; Berlin 23.6; Leipzig 22.7; Hamburg 22.4; Cologne 17.7; Frankfort a. M. 13.7; Strasburg 33.1.

In the 28 English towns, with an estimated population of 8,469,571, for the week ending December 9th, the death-rate was 23.4. Deaths reported 3794: acute diseases of the respiratory organs (London) 447, measles 119, scarlet fever 110, whooping-cough 81, fever 81, diarrhœa 39, diphtheria 29, small-pox (Newcastle six, London five, Wolverhampton and Nottingham one each) 13. The death-rates ranged from 16.2 in Derby to 35.5 in Sunderland; Brighton 17.6; Bradford 20.6; Birmingham 21.6; London 22.4; Manchester 23.3; Sheffield 24.8; Liverpool 29; Leeds 31. In Edinburgh 22; Glasgow 30.8; Dublin 24.9.

For the week ending December 9th, in the Swiss towns, population 494,390, there were 36 deaths from consumption, acute diseases of the respiratory organs, 30, diphtheria and croup 12, diarrhœal diseases nine, typhoid fever five, whooping-cough three, measles one. The death-rates were, at Geneva 7.2; Zurich 24.3; Basle 16.3; Berne 27.6.

The meteorological record for the week ending December 23d in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

DOUBLE OSTEOTOMY AND OSTEOCLASIS. A CORRECTION.

MR. EDITOR, — The illustrations for the article in your last issue, A Case of Double Osteotomy and Osteoclasis, have been misplaced, so that it appears that the limbs were more crooked after osteoclasis. This was, of course, not the case. For "Fig. 3, after osteotomy," read "Fig. 4, after osteotomy and osteoclasis (front view)," and for "Fig. 5, after osteotomy and osteoclasis (front view)," read "Fig. 3, after osteotomy."

Yours truly, E. H. BRADFORD.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 22, 1882, TO DECEMBER 29, 1882.

PERIN, GLOVER, lieutenant-colonel and surgeon. Granted leave of absence for one month from the 19th instant. S. O. 217, Department of Dakota, December 20, 1882.

BILL, JOSEPH H., major and surgeon, will report to the commanding officer, Fort Omaha, Neb., for duty. Paragraph 4, S. O. 134, Department of the Platte, December 21, 1882.

KILBOURNE, H. S., captain and assistant surgeon. Granted leave of absence for one month, with permission to apply through headquarters, Military Division of the Missouri, for an extension of two months. S. O. 218, Department of Dakota, December 21, 1882.

MADDOX, T. F. C., assistant surgeon. To report to the commanding officer, Fort Clark, Texas, for duty. S. O. 138, Department of Texas, December 16, 1882.

REED, WALTER, captain and assistant surgeon. Relieved from duty as attending surgeon headquarters Department of the Platte, and will report in person to the commanding officer, Fort Omaha, Neb., for duty. S. O., 134, Department of the Platte, December 21, 1882.

TURRILL, H. S., captain and assistant surgeon. Upon being relieved from duty at Fort Omaha, Neb., will proceed to Fort Fred. Steele, Wyoming, and report to the commanding officer of that post for duty thereat. Paragraph 5, S. O. 134, Department of the Platte, December 21, 1882.

SUFFOLK DISTRICT MEDICAL SOCIETY. THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE will meet at 19 Boylston Place, on Wednesday evening, January 10th, at 7.45 o'clock. Dr. E. F. Cummings will exhibit the Genital Organs of a Hermaphrodite, with casts and drawings, and a description of the clinical features during life. Dr. A. N. Blodgett will show a specimen of Carcinoma of the Ovary with Cystic Degeneration. ALBERT N. BLODGETT, *Secretary*.

A SIMPLIFIED EVACUATOR FOR LITHOLAPAXY,

BY HENRY J. BIGELOW, M. D.,

Surgeon to the Massachusetts General Hospital; Emeritus Professor of Surgery in Harvard University.

The operation for the immediate removal of a calculus through a catheter, like many other surgical operations, can be accomplished more or less satisfactorily by any one of several instruments which much resemble each other. But it can be done better by employing a more perfect apparatus than those now generally in use. It has been said that "no new form of instrument is required by this operation," which is true so far as it implies that neither a lithotrite nor an evacuator is a new instrument. But it would be a mistake to infer that the operation could have been done with the instruments of the old lithotrity, and that they had needed no change to adapt them to what is now required of them, or that they cannot be still further modified to advantage. The new operation cannot be performed with the old instruments. It requires a larger evacuating catheter than that of Clover, through which the usual product of the lithotrite could not pass, except powder and sand, and that only in limited quantities, because the other detritus obstructed the entrance of the tube.[1] Though at first received with a good deal of distrust, the large catheter has been finally adopted by all the surgeons who have done the operation, and, in fact, cannot be dispensed with. It should be combined with a thoroughly efficient aspirator. But no particular form of aspirator has so far met with general approval. Though better than it was, surgeons have none as yet which entirely satisfies all requirements of the operation, and is at the same time compact and convenient to handle and simple in construction. This part of the evacuator still needs improvement.

The usual parts of an evacuator, not including the catheter, are these: —

(1.) The exhaust, the best form of which is an elastic bulb.

(2.) A space or trap for air, at the upper part of the instrument.

(3.) A glass receiver at the lower part, to collect and show the débris.

In drawing out fragments from the bladder through the large catheter, one bulb or aspirator, if strong enough, is about as efficient as another. An aspirator of almost any shape, and having almost any combination of its parts, will do this. So will a mere elastic bulb attached directly to the catheter, without joints or receiver, if it is placed lower than the catheter, bent down like the body of a retort, so that the fragments can fall to the bottom of it; and the instrument will still work well if it has joints made, for economy, of cork or rubber instead of metal. But however otherwise arranged, a satisfactory aspirator should have —

(4.) Some device, near the catheter, to act as a trap for débris and secure every fragment that has passed it.

The chief difference among evacuators now is in the certainty with which they retain the fragments they have aspirated. Any instrument will draw out the fragments, but few hold them securely, for the débris do not always fall into the glass receiver nor do they always remain in it. On the contrary, they are easily carried back to the bladder. This defect in the action of the evacuator has received little attention from surgeons, although it is the only point connected with the instrument which offers any difficulty whatever. Until recently it has been remedied only by sacrificing simplicity in the apparatus.

In endeavoring to make a satisfactory evacuator for litholapaxy many experiments have to be tried. It is quite possible that a perfectly satisfactory instrument might have been contrived some time ago if it had been generally understood that an evacuator that works best with pieces of broken coal in a vessel of water will succeed best with the fragments in the bladder.[2] So also will the surgeon if he is otherwise well qualified. It is true that the living tissues are easily injured, but in other respects the experiment can be made sufficiently like the operation to give it great value. Aspirating débris from the bladder is not a question of pathology, but of operative surgery, of physics. And in view of the fact that we fail, in some bladders, to discover a last fragment even by repeated washing, an evacuator should be so constructed that it will absolutely prevent a fragment that has once passed the catheter from returning to the bladder to become the nucleus of another calculus.

It is not altogether easy to meet this requirement, because the solid particles are usually borne back and forth with the current of water. In a common evacuator they are carried wherever it goes, first from the bladder to the bulb, and then, when it is reversed, back to the bladder, a part only falling into the receiver at each aspiration. As we may fairly assume that a surgeon would not deliberately inject foreign bodies into a patient's bladder, there must be something wrong in a system which obliges him to do this, and makes it necessary to aspirate the same débris twenty times over in order to remove it. In short the apparatus, as commonly arranged, is still a defective one, and needs some special contrivance to assist the action of gravity in securing the débris.

Surgeons have long felt this. The use of a long elastic tube connected with the catheter has been more than once criticised, and with some reason, on the ground that it might contain fragments which would be returned to the bladder. And, again, in order to

[1] Sir Henry Thompson says (Diseases of the Urinary Organs, Philadelphia and London, 1882): "The evacuating catheter to be attached to the aspirator should be as large as the urethra will admit; usually No. 15 or 16 of the English scale [26 *to* 28½ *French*] may be used without any danger. Sometimes No. 17 or 18 [30 *and* 31 *French*] are admissible; but such sizes are quite unnecessary for small stones, and may produce mischief; hence they are only to be used where the presence of a large stone demands corresponding instruments." Or, it might be added, to expedite the operation, when the urethra is large and healthy. The size of the normal urethra, according to Otis, is, if we except the meatus, 32 of the French scale. Clover's evacuating catheter was 21. Those now in use range from 26 to 31. Care, however, and often special skill may be required to introduce safely the largest sizes; 31 is very rarely needed, and the French sizes 28 and 29 are generally the most convenient. For a final washing or sounding without anæsthesia, when it is desirable to give the patient the least discomfort, even so small a calibre as 26 is sometimes useful. Through a catheter of this calibre Mr. Teevan has removed calculi weighing six or eight hundred grains, but such cases should be regarded as showing what is possible rather than as establishing a rule of practice. Here I may add that although no lithotrite compares in size with the larger tubes, it is yet true that long-bladed lithotrites, especially if they have the sharp extremity of the old instruments, are more difficult than tubes to introduce with safety. Although since 1878 my lithotrites have been made in three sizes, I have rarely had occasion to employ any other than the middle size.

[2] The specific gravity of hard coal is 1.575. That of a urate calculus is 1.540, and of a mulberry calculus 1.262.

shorten by an inch the route from the bladder, a less convenient stop-cock has been substituted for the usual one. But lithotritists should be fully aware of the fact that whether there is an elastic tube or not a tenfold greater quantity of fragments is generally driven back out of the bulb itself, and that the difficulty lies almost wholly in that part of the instrument. At each expansion débris are drawn from the bladder into the bulb, where they are delayed until, when it is compressed, they are injected back into the bladder. Only a part of them, sometimes only the larger half, the quantity varying in different instruments, settle into the glass receiver. This important fact, so little recognized, should not be accepted without demonstration.

An instrument which Sir Henry Thompson has lately abandoned (Fig. 1) can be made to demonstrate exactly how the currents act upon the fragments in an evacuator which is unprovided with a catheter-trap to prevent them from reëntering the catheter. It is here selected because the peculiar form of this instrument makes it easy to fit a glass tube to it so that we can see what takes place in the interior. Let a piece of glass tube an inch in diameter be inserted at the joint JJ, between the bulb B and the catheter, to show what passes with the current from one to the other in either direction. If the end of the catheter be now placed in a suitable vessel of water containing fragments of coal of different sizes, while the bulb is alternately compressed and allowed to dilate, a continued stream of fragments will be seen rising from the vessel into the bulb, and then returning to the vessel, as they inevitably do to the bladder. The backflow of débris can be still better watched if a glass tube be also substituted for the catheter, as in the figure.

But there is another important fact illustrated by this instrument. Fragments do not always stay in a receiver after they have been deposited there. When the glass receiver R of this evacutor is half filled with fragments a part of these are easily carried back into the bladder or into the vessel. They are first lifted up from the receiver into the bulb, and then driven out through the catheter. For though the orifice of this glass receiver is small and protected by a special trap, the current and débris pass out of it as well as into it. It could not have been foreseen that fragments would escape from a receptacle apparently so well arranged. But it will be found that in any instrument, if the bulb or catheter directs the current into the glass receiver, whether directly or obliquely, fragments are easily carried out again.

And the general result is little better, if, to avoid stirring the fragments which lie in the receiver, the current is directed horizontally over the mouth of it instead of into it. Some of them then pass directly back and forth between the bladder and the bulb, over the receiver, without falling into it. This defect can be shown in an instrument recently employed by Sir Henry at the suggestion of Weiss & Co.,[1] where the stream from the catheter passes horizontally through an empty chamber on its way to the bulb. As the stream enters it its velocity is so diminished that fragments fall to the bottom into the receiver, in greater number when the bulb is weak. Many fragments are, as usual, secured. But in order to be wholly effectual the chamber intended to retard and break up the current by its size would have to be inconveniently large to give time to the floating débris entering on one side to settle into the receiver without passing further. The principle here involved is quite different from that of

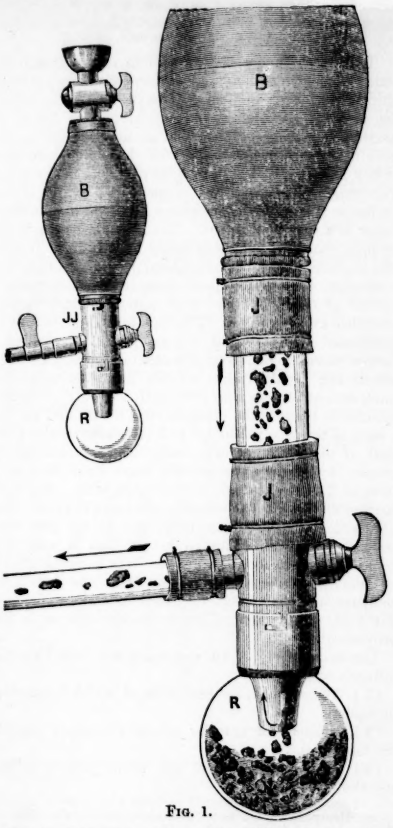

FIG. 1.

B, Bulb. R, Receiver. J J, a Joint.

These two figures, representing the same instrument, are intended to illustrate the fact that all evacuators return fragments to the bladder unless provided with some especial arrangement to retain them. The joint JJ of the smaller figure is opened in the larger figure to receive a glass tube. Through this fragments are seen as they are drawn into the bulb and expelled from it. The glass evacuating catheter shows them again, on their way to and from the bladder.

The receiver R shows other fragments in the act of being lifted by the current and returned to the bladder.

the evacuator represented in the above figure. Weiss's instrument is not unlike one formerly figured in the *Lancet*,[2] but the valve and strainer which there act as a trap have been omitted, and, in consequence, not a few fragments escape back to the bladder.

In Weiss's evacuator again, some of the fragments which enter the bulb gather in the bottom of it, which is lower than its outlet, and where there is no receiver to collect them. The chief difficulty, however, is not

[1] Lancet, January 7, 1882.

[2] Lancet, September 24, 1881, figure 5.

that these fragments stray into the bulb, but that for want of a trap they are afterwards liable to escape out of it to the bladder.

This difficulty is not wholly obviated by placing a strainer across the mouth of the bulb to prevent the fragments from entering it, as has been done in some other evacuators. Let me mention in this connection the results of a former experiment. It might be supposed that if the passing fragments were arrested by a flat strainer placed across the current, whether at the orifice of the bulb or elsewhere, they would fall into a glass receiver placed directly below them. But this is not the case. Though a large part fall into it, others collect upon the strainer, and unless the operator pauses after each aspiration till they have settled quietly into the receiver they are liable to be carried back by the current, if it is as strong as it should be. This has happened, in my own experience, whether the strainer was horizontal, vertical, or oblique. The fragments do not glance from it down into the receiver, but some of them cling to it until the current is reversed, and then go back. To make a strainer act as a trap the fragments should pass freely beyond it, and be intercepted only on their return. They will then be strained away from the bladder and not towards it. It is very desirable that the current should be unobstructed while the bulb is expanding, whether by a strainer or by curves and angles in the tubes. A simple flat strainer, placed anywhere across the whole current, retards it, especially if the urine is flocculent.

I find that the simplest expedient for collecting the fragments so that they will settle undisturbed in a glass receiver is to admit them into the bulb, and prevent their escape from it. After many experiments I have found nothing more effectual for this purpose than a straight cylinder with perforated walls, which is practically a prolongation of the catheter into the bulb. The water after bringing the fragments from the bladder is strained as it returns. To the open end of this perforated cylinder a valve might be attached, either a ball-valve moving loosely,[1] which is less liable to obstruction than a valve with a hinge, or, still better, at the same point, half an inch of cotton tube, which opens, allowing the fragments to pass up through it, and collapses with the reversed current, cutting off their retreat, the water, as it returns, passing back through the perforated walls. In operating with this arrangement I have found it to work perfectly, but a valve is not necessary, and the apparatus is more simple without it.[2]

The evacuator described below is more simple in construction, and aspirates more perfectly than any I have used. It is shown in Fig. 2, and is a compact modification of one formerly published in the *Lancet*[3] as "a simplified evacuator," but without the stand of that instrument, which is not essential, and has been omitted because operators seem to prefer to do without it.

The catheter is made to enter a spherical bulb obliquely upwards, and is prolonged to the centre of the cavity by the tube just referred to, open at its end and

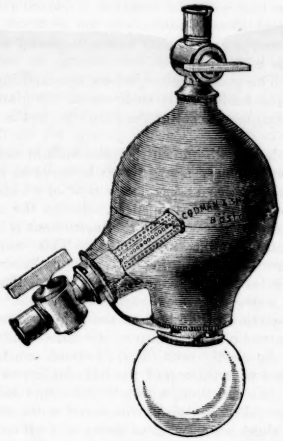

FIG. 2.

The writer's evacuator. It has an elastic bulb, glass receiver, and stop-cocks. Below there is a metal brace between the collar of the glass receiver and that of the catheter to steady the latter. Within the bulb, and open at the end, is a tube strainer to prevent the return of débris. The bulb forms a concentric handle to the catheter.

perforated on its sides with numerous holes, which act as a strainer. The catheter, tube, and elastic bulb are in a straight line. This arrangement has the great advantage of *not deflecting the current* and thereby diminishing its force. During aspiration the current bearing the débris is drawn straight from the bladder through the tube, into the widest part of the bulb, and the fragments, spreading there, fall towards the receiver. But when the bulb is compressed the water returns mostly through the perforations in the side of the tube because their area is collectively larger than the opening at the end of it, and because they are nearer the point at which the water passes out of the bulb. By means of this simple contrivance the water is strained, and *the return of fragments is practically prevented.* The tube strainer can be removed, cleaned, and replaced in a moment, and this is an advantage when there is much mucus, coagulum, or shreddy material in the urine, by which the holes of any strainer may be partly obstructed. Even then this tube continues to work well, but it is better to pass a brush over it if mucus adheres to it. It can be examined as often as the receiver is emptied. After the water has once been changed less mucus will be found.

The action of the perforated tube meets all requirements. In fact if the catheter is prolonged into the bulb by a tube which has no perforations in its sides, the instrument will perform very fairly. Such a tube might be fastened permanently in the bulb, but the apparatus can be kept cleaner if there is a joint through which it can be removed. The cavity of the bulb cannot be made too accessible.

[1] Ibid., September 24, 1881.

[2] A hinged or other valve strainer at the mouth of the catheter, if it opens to allow the water and the débris to pass through, works well enough as a substitute for the tube strainer. The catheter then opens directly into the bulb, and the route is the shortest possible one. But the tube strainer is much more simple, and the two inches which it adds to the length of the catheter are quite unimportant. In fact, the usual length of the catheter itself might be reduced two inches to shorten the route if desired. For strainers and strainer traps see Lancet, September 24, 1881. As there described, they are used in pairs, one protecting the entrance of the bulb, while the other, furnished with a valve, and placed at the head of the catheter, acts as a trap. The former, for reasons already given, is not always advantageous, but an effectual catheter trap to arrest returning fragments is necessary.

[3] Lancet, September 24, 1881, Figs. 8 and 11.

The above arrangement has several other advantages.

(1.) With the trap placed inside the bulb, the instrument is more compact, shorter, and more easily held, and as the spherical bulb is here placed in a straight line with the catheter, it forms a concentric handle, which enables the surgeon to direct the catheter better than when this handle is placed above it, at an angle with it.

(2.) The glass receiver is here attached immediately below the bulb, and is easily seen. A glass cylinder shows fragments better than a globe, but is less capacious.

(3.) It is well known that the bulb in action, especially when placed above the catheter, at an angle with it, communicates an oscillation to it of which some patients complain. By a special device the catheter is here made so steady while the instrument is in use that a separate stand is not wanted. This consists of a brace uniting the metal collar of the catheter with that of the glass receiver, and so steadying it that *the catheter no longer feels the movement of the bulb.* The conical projection of the bulb at the point where the catheter is attached contributes to the same result.

(4.) An elastic hose (Fig. 3) which can be quickly connected with the top of the bulb facilitates the operation. We can then, with a single compression of the bulb, get rid of any air or discolored water, and replace it with clean water without delay and without uncoupling the catheter. Besides, no matter how the bulb may have been filled at first,[1] it is better to be able to vary the quantity of water at any moment afterwards, and although without a hose we can add water through a tunnel, we cannot as easily withdraw it in the same way. We should be able to regulate the amount of water carefully, not only at the outset according to the capacity of the particular bladder, but also during the operation. For example, it is sometimes desirable to draw it quickly away to allow for the muscular strain of retching, or to relieve the expulsive efforts of the bladder itself which sometimes becomes very tense, and ejects water at the side of the catheter, even the large ones. More water is required at first, while fragments are numerous, to separate them and prevent their being wedged in entering the catheter. Later in the operation, less water makes it easier to find the last fragment, the minimum being reached when the wall of the bladder vibrates against the orifice of the catheter as the bulb expands, painfully if the patient is conscious. It is then important to add water again, just enough to prevent this obstruction and no more. In short there is no doubt that we can evacuate better by trying a little more or less water from time to time during the operation, and that this can be done more accurately and more readily by means of a hose than in any other way. With one end attached to the bulb the other can conveniently remain in a vessel placed between the patient's knees, or in any convenient position, or remain unattached till wanted.

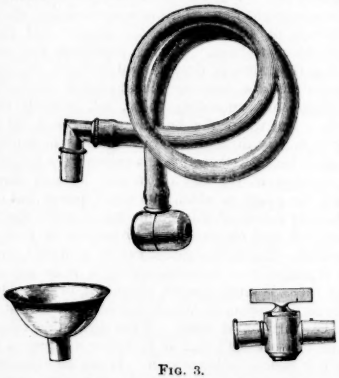

FIG. 3.

Apparatus belonging to the evacuator but not essential to it, namely, a tunnel and a hose, both of which fit on to the top of the bulb, and an extra stop-cock for the evacuating catheter.

The hose may be used or not. For those who prefer a tunnel (Fig. 3), one is furnished with the instrument; as also a second stop-cock (Fig. 3), which I find useful, if attached to the head of the catheter, in keeping the bedclothes dry when the bulb is to be removed.

This evacuator is made by Codman and Shurtleff, Boston.

[1] We can quickly fill the evacuator from a pitcher, if we invert the bulb and detach the receiver. The little remaining air can afterwards escape through the hose or tunnel.

ON SUDDEN DEATH BY THE ENTRANCE OF AIR INTO THE UTERINE VEINS.[2]

BY F. W. DRAPER, M. D.

IT is obvious on a moment's reflection that of the various channels by which air may enter the circulation, the pregnant or puerperal womb, by its situation, anatomical structure and relations, and functional changes incidental to gestation, is peculiarly exposed to this accident. Two conditions only are required in order to precipitate the mischief; the first is that there shall be air in the cavity of the uterus, and the second is that the uterine veins are open, either at the placental site or in other parts of the interior of the womb.

Let us note briefly what may be presumed to happen in the presence of such favoring conditions in the pregnant womb. What probably occurred, for example, in the second of the two cases reported in this paper? The woman submitted herself to a vaginal examination and to local instrumental manipulation at the hands of the attending physician, whose purposes both the parties understood. His finger in the vagina canalized that passage, whose walls in their normal state would be in apposition; free entrance of the external air would thus be facilitated, the position of the woman on the bed, by diminishing the intra-abdominal pressure, acting favorably to the same end. His sound or stiffened catheter, guided by his finger at the os uteri, was passed through the cervical canal, leaving its tell-tale marks in the sub-pubic tissues and on the mucous membrane of the posterior wall of the canal of the cervix. The design (if such had been formed) to puncture the fœtal membranes failed of accomplishment; the point of the instrument slipped backward toward the sacrum, and in its course tore away the deciduous membrane from the uterine wall. This membrane, so loosely adherent to the uterus when the

[2] Concluded from page 7.

fœtus is mature, and so readily cast off in the course of normal labor, was in no condition, at this stage of its development, to bear violent meddling. The womb, already in the eighth month of gestation, and preparing presently to put into exercise its powerful contractile forces in parturition, resented the premature interference with its contents, and, under the influence of the artificial stimulation, contracted; relaxing again, it established a partial vacuum in its cavity, into which, alongside the instrument, or, if it were a catheter, through it also, a quantity of air was drawn from the vagina. If this air now in the womb could have been wholly expelled through the same passage by which it entered, no harm would have followed; but this fortunate result did not occur. The air, when next the womb contracted, as it would speedily do under the added stimulus of atmospheric pressure within its cavity, would seek the readiest outlet; and this was not altogether into the vagina. The instrument in the hand of the operator was not pushed once forward and then withdrawn; it was worked or moved from side to side as far as the narrow utero-vaginal passages would permit, to make certain that the membranes were injured enough to insure a miscarriage; this action violently separated the decidua from the uterus over a V-shaped area, and tore open many of the uterine veins. These large canals, usually wide open in consequence of their relation to the muscular tissue which surrounds them, freely inosculating in all directions and unprovided with valves to prevent a reversed current of their contents, received into their easily accessible channels a part, at least, of the air which had been sucked into the womb. Meanwhile, another set of forces came into operation; the normal rhythmical action of the heart and lungs draws the venous blood to the right auricle from all parts of the body; its effect, so marvelously adapted to our needs in health, may become in some emergencies the source of gravest danger, as when it takes up and transports to the heart the bit of thrombus from an iliac vein inflamed after childbirth, to become in turn the potent breeder of fatal mischief when the right ventricle sends it onward into the pulmonary artery. So, in the present instance, by the same force, the contents of the uterine sinuses (air and blood) were drawn easily and quickly through the uterine plexus of veins into the great venous highway to the heart. Arriving there, the unnatural mixture would cause disturbances easily comprehended; apparatus designed to propel thick fluid cannot manage air, and just as the farm-yard pump behaves when its "box" needs repairs, so now the heart finds its valves unequal to the call upon them; the air goes partly to the lungs with each systole to make new trouble there, in part backward to the auricle whence it came to distend that cavity still farther; each diastolic relaxation draws more air from the womb, and thus, the favoring conditions continuing, the process goes forward till the heart, over-distended on its right side with spumous blood, refuses longer to act and succumbs in death. The lungs meanwhile have ceased to do duty; the blood conveyed in a broken current to the air-vesicles cannot be adequately renewed, and asphyxia plays its appropriate part in helping to destroy the patient. Some portion of the air, indeed, may succeed in accompanying the blood through the pulmonary circulation back to the left ventricle of the heart to be distributed through the arteries; but this is secondary in its relation to the main elements of the emergency, and means simply that the patient has survived sufficiently long for the round of the circulation to be accomplished.

Such, we may believe, is the mechanism of the attack which atmospheric air may make upon the citadel of life when it has access to the thorax by unusual channels. And that which may occur while the womb still carries its fœtal contents may happen with equal or greater facility immediately after delivery. "The mechanism," says McClintock,[1] "by which the introduction of air into the veins can be effected, admits of being explained in a few words. The veins of the gravid womb present four remarkable characteristics, namely, their extraordinarily large size, their freedom of inosculation, the total absence of valves, and their termination on the internal surface of the uterus, at the site of the placenta, by large open orifices. If the uterus be examined soon after delivery at the full term, the majority of these apertures will readily admit a goose-quill, and some will even allow the little finger to penetrate without laceration." And Simpson[2] thus graphically describes the way in which air enters the circulation in consequence of these favoring circumstances: —

"The interior surface of the organ [the womb], especially opposite the late seat of the placenta, has a number of ruptured venous orifices opening upon it. Supposing air once introduced into the uterine cavity, which in some cases may occur in consequence of the alternate relaxations and contractions of the walls of the organ, and supposing, further, that, under the returning contractions of the organ, the expulsion of this air was prevented by a clot at the os uteri, or other such obstructing causes, it will, then, under the compression to which it is subjected, be liable to be driven into the open venous orifices." And that which these eminent obstetric authorities long ago explained on theoretical grounds has been demonstrated clinically by a sufficient number of well-authenticated cases.[3]

The precise mode in which air destroys life in these instances is still largely a subject of speculation. That air admitted through the large veins to the heart usually kills has been conceded as a demonstrated fact for many years; but why and how it kills is a problem upon which the authorities in pathology, physiology, and obstetrics have not reached substantial agreement. Ever since Lagallois,[4] in 1829, first called attention to the obstetric relations of the subject, there has been no lack of theories to elucidate the proximate cause of death in these cases, and the great variety of these theories and the ingenuity of many of them attest the difficulty of the question. Some, of whom Bichat is the earliest representative, have maintained that air kills by its effect on the brain, causing cerebral anæmia. Others, like Nysten, Dupuytren, Amussat, and Magendie, have held that the mechanical effects of air in the right cavities of the heart, pro-

[3] Those who care to pursue the subject farther in this connection will find the following writings of interest: Cormack: Clinical Studies, vol. ii., 1876. Greene: On the Presence of Air in the Veins as a Cause of Death. American Journal Medical Sciences, 1864, vol. xlvii., page 38: Esleben: Plötzlicher Tod in Folger von Lufteintritt in die Uterin-Venen, 1876. May: Cases of Sudden Death after Parturition, with Air in the Veins. British Medical Journal, 1857. Olshausen: Ueber Lufteintritt in die Uterus Venen. Monatschr. f. Geburtskr. u. Frauenkr. 1864. Kezmarszky: Ueber Lufteintritt in die Blutbatuen durch den Puerperalen Uterus. Arch. f. Gynækol., Bd. xiii., page 200.
[4] Annales Hebdom. de Médecine, vol. iii., page 183. Paris, 1829.

ducing over-distention and cardiac paralysis, brought about the fatal issue. Still others (Erichsen, Virchow, Oppolzer, Spiegelberg, Panum) maintain that asphyxia, or death at the lungs, is the true explanation, the air which passes into the veins at a distance from the heart entering the circulation of the lungs in fine bubbles and forming air-emboli in the lesser divisions of the pulmonary artery with as sure an asphyxiating effect as if a thrombus had obstructed the main trunk. Cormack urges the view that the first shock which the vital functions sustain is caused by a rapid distention of the right auricle, and its inability to contract on its elastic contents; if the distention be complete and rapid, instant death is the result; if death does not almost at once close the scene the phenomena of asphyxia will supervene. Bouillaud believed that death approaches from three directions: (1) by over-distension of the heart; (2) by the presence of spumous blood in the pulmonary artery preventing the free passage of blood through the lungs; and (3) by the irritative effects of the air on the brain, producing coma. It can hardly be profitable to multiply illustrations of this diversity of opinions. The drift of the later writings appears to be toward the German theory of air-embolism, although it is plain that this explanation is not without its difficulties.

What are the *symptoms* by which the mischievous presence of air in the circulation is declared? Although this is the most important part of the subject to practical physicians, it is difficult to set forth these indications with exactness; for the attack is itself a brief one, full of startling effects, and its phenomena follow in such rapid succession that, as Playfair observes concerning a similar grave emergency, "symptoms have not been recorded with the accuracy of ordinary clinical observation." Moreover, the majority of these cases do not fall under medical observation at all, and one must then take simply the imperfect account which frightened attendants and friends can give. But we may gather from the authentically recorded cases a tolerably clear notion of what transpires. If the air does not reach the heart in sufficient amount and rapidity to destroy the patient instantaneously by shock and "without a sigh, groan, or struggle," a series of symptoms like the following may occur: The woman changes color, turns ashy pale or livid, gives a low moan, and gasps for breath. If she speaks at all before she loses consciousness, it is in tones and words which express her horrible apprehension of impending danger, and the exclamation "I am dying!" often tells but too truly her mental distress. The pulse quickly becomes extremely small, rapid, and irregular. If the stethoscope be placed over the heart the sounds heard may clearly indicate the violent churning action to which the mixture of air and blood is subjected in the right auricle and ventricle. The respiration, at first hurried, and spasmodic, suggesting what a German writer expressively calls "air-hunger" (luft-hunger), immediately becomes slower, and ceases while yet the heart's action continues. Meanwhile the patient has fallen as in a faint; the features are fixed, the eyes staring or turned upward, and insensibility becomes complete. A convulsion generally occurs just before death. In some cases a scarlatinoid rash replaces the livid pallor of the skin, but this is a rare phenomenon, and does not occur in the rapidly fatal cases.

This is the brief clinical story. It is not contended that all instances are alike in their course and termination; the quantity of the air introduced and the rapidity of its introduction are the two controlling factors. On the one hand a small amount of air may enter a vein with only slight and temporary inconvenience to the patient; and, on the other hand, a large volume of air may rush to the heart with such rapidity that, in the language of Sir Charles Bell,[1] "neither violence, nor loss of blood, nor even the bursting of the aorta, nor nervous influence, produce effects so sudden and appalling, as by a lightning stroke." It is plain that, in obstetric practice, the risk is that if air can enter the uterine sinuses at all it will probably enter rapidly and in large volume, and thus produce the graver form of peril with its attendant symptoms. Under normal conditions nature kindly averts disaster of this sort by shutting the large open orifices of the uterine veins as soon as the fœtus and placenta have been expelled; a clot plugs the mouths of the vessels, and the contracting uterine muscle brings into close apposition walls of venous canals which the same muscle has hitherto held widely apart. If these preventive conditions are delayed and the womb lies in the abdomen like a flaccid bag, it is in just the state to invite the catastrophe of air embolism in its most serious form.

The question readily occurs, How can the attendant distinguish the symptoms of air in the circulation from other similar forms of emergency in the lying-in room? Of the various extreme and usually fatal casualties to which the puerperal patient is exposed, that which most resembles the one under discussion in its clinical features and result is the sudden obstruction to the pulmonary circulation either by the formation of a thrombus in the right side of the heart or by the plugging of the pulmonary artery, the so-called pulmonary embolism. Playfair says[2] that "there seems to be no essential difference between the symptomatology of spontaneous and embolic obstructions"; and again, that "the symptoms observed in fatal cases of air-embolism closely correspond to those of pulmonary obstruction." Practically the differential diagnosis is of less consequence than it would be if these startling attacks were less brief in duration and gave to the attendant more chance to study and compare the symptoms; and if, too, a successful course of treatment depended here, as much as it does under other circumstances, on accurate knowledge of the invasion. There are, however, some points which offer themselves upon a study of recorded cases whereby one of these emergencies can be distinguished clinically from the other. The time of the attack differs in the two cases; air enters the uterine sinuses, if it enters at all, while their orifices are still recently exposed, and thus the accident occurs ordinarily just after childbirth or while the abortionist is still at his work; pulmonary embolism, on the other hand, is oftenest observed several days after the womb has been emptied, and is a secondary complication of the puerperal condition, depending largely on wandering clots from distant veins inflamed and plugged some time after the delivery. Another difference relates to the attack in its progress; in pulmonary obstruction we are told[3] that "the intelligence during the struggle is unimpaired, and the dreadful consciousness of impending death adds not a little to the patient's suffering and to the terror of the scene;" in the other exigency, on the contrary, the patient almost immediately becomes

[1] Practical Essays, 1841, page 11.
[2] System of Midwifery, 1880, page 618.
[3] Playfair, op. cit., page 619.

unconscious at the onset of the accident and has hardly time to utter any exclamation before she seems to the by-standers to have fainted. A convulsion is the rule in the course of air-embolism; it is not reported often in connection with pulmonary obstruction. Finally, the stethoscope may assist in diagnosis; in the presence of a considerable quantity of air in the heart, provided the life of the patient continues long enough for the attendant to get his instrument adjusted, he may hear a peculiar and unmistakable sound which Cormack [1] describes as a "churning sound," indicative of the irregular and ineffectual efforts of the heart to rid itself of its unnatural contents.

But he must be a ready-witted and remarkably calm practitioner who can do more than guess at his diagnosis in the presence of either of these disastrous accidents, and the autopsy is probably, after all, the only trustworthy means of settling the question.

Can anything be done to avert the mishap of air in the veins, or to arrest and control its effects when once it has occurred? Upon the prophylactic side, it is obvious, in view of the ætiology, that all operative or simply exploratory acts liable to promote the admission of air to the uterine cavity, and all measures of treatment attended with similar risk either to the pregnant or the puerperal womb, should be avoided or carefully hedged about with precautionary recognition of the danger. It is no part of the purpose of this paper to give any warning counsel to abortionists to the end that they use greater care in their manœuvres; it is best, in the long run, for womankind, it is certainly best for legitimate obstetrics, that occasionally a woman should die suddenly in the abortionist's office, and that he be held responsible for her death before the courts. But it is fair to raise the question whether the methods most in vogue for the induction of justifiable abortion are sufficiently free from hazard. Barnes [2] condemns the douche, whether vaginal or intra-uterine, and speaks of the "warnings conveyed by many fatal catastrophes," among which he mentions the very accident which we have under consideration. Is the plan, so generally adopted, of introducing a bougie or catheter into the uterus, outside the ovum, and allowing it to remain there for hours, an entirely harmless procedure? Does not the older and equally sure method of the direct puncture of the membranes, if done properly, offer greater safety to the mother?

And that which applies to the gravid uterus applies equally to the womb just evacuated; air is not a safe tenant to take the place of the fœtus. Until the process of involution is fairly begun, and the chance of renewed relaxation of the uterus is passed, we have in the risk of air embolism, through sudden changes of posture, an added reason why the woman in childbed should remain quietly in a supine position. If intra-uterine disinfectant injections are used the greatest care should be taken that the valves and joints of the syringe are tight, and that all air is expelled from the nozzle before it is introduced. It is not improbable that some of the instances of temporary collapse which have been reported as occurring in the course of such injections may be traced to carelessness in their administration and to the projection of a small volume of air into the exposed veins at the placental site. The temporary use of the obstetric binder has a plain prophylactic justification.

[1] Clinical Studies, vol. ii., page 136.
[2] Obstetric Operations, page 307.

If the medical attendant happens to be present when his patient is overwhelmed by the casualty of air entering the uterine veins, he will best show his skill by directing his measures of relief to the heart, and by applying such remedies as will stimulate that organ to continued action so that it may perchance empty itself of its atmospheric contents, and get renewed supplies of its normal stimulant, the blood. The hypodermic injection of ether, or, if that is not at hand, of brandy or whiskey, and the injection of ammonia into a vein, would best serve this purpose. The application of the Faradic current would help in the same direction.

But in general, in these cases, the emergency has passed, and the patient has succumbed before the attendant can reach her bedside to show his skill and his coolness. It usually is his simple privilege to make a post-mortem visit, and to try then to discover the cause of the catastrophe. In pursuit of this search he will not forget the important, the supreme aid, indeed, which the autopsy can give him.

PROGRESS IN OBSTETRICS.

REPORTED BY WM. L. RICHARDSON, M. D.

TREATMENT OF ABORTION BY HOT WATER INJECTIONS.

Dr. Whitwell states [3] that the advantages of injecting hot water into the uterus and vagina in the treatment of abortion are: First. The existing hæmorrhage is stopped almost instantly, and there is but little liability of return while the douche is continued. Second. There is seldom any necessity for instrumental interference. Third. The patient, who may be in a state of partial collapse, is revived by the application of heat. Fourth. The keeping the vagina full of water allows the hand to operate with greater freedom. Fifth. There being no fear of hæmorrhage, the operator can work leisurely, and violence is unpardonable. Sixth. By carbolizing the water septicæmia is guarded against. Seventh. Nothing can be suggested which would be more likely to save the patient from pelvic inflammation with its attendant evils. Dr. Whitwell's practice is as follows: Supposing the miscarriage inevitable, should the os be closed and the hæmorrhage not severe, and, from the indications, it appeared safe to temporize, he would tampon the vagina as thoroughly as possible with either styptic cotton or simple carbolized wads of absorbent cotton. The chances are that when this was taken away the os would be found to be dilated, and the ovum ready to be discharged into the vagina. If the os were closed, the membranes having ruptured, and it were necessary to take active measures at once, he would advise the use of an anæsthetic, feeling sure that the dilatation would then be a matter of little difficulty. If, on the other hand, the os were open, and the ovum presenting, he would inject the hot water into the vagina, and thus stimulate the contractions of the uterus. If this were not sufficient, either the nozzle of the syringe or an attached catheter could be passed within the cervix, and the hot water be slowly injected. Under this stimulus the uterus would quickly force the ovum into the vagina with but little manual assistance, and all hæmorrhage would cease. Should there, unfortunately, be any retention of a portion of the ovum or membranes, he

[3] London Medical Record, June 15, 1882.

would wait and use the hot water again as soon as any oozing appeared.

TREATMENT OF PUERPERAL ECLAMPSIA.

Dr. Carl Breus reports [1] six cases of puerperal convulsions treated by diaphoresis, with only one fatal case. The patient is put into a hot bath (100.4° F.), and the temperature is then raised as high as the patient can bear it, care, of course, being taken to keep the face above the surface of the water. The patient is kept in the bath about half an hour, or until a profuse diaphoresis appears on the head and face. She is then wrapped up in a sheet, and around her are wound several warm, thick blankets, her face being left uncovered so as not to impede the respiration. If the patient complains of thirst she is allowed to drink moderately of soda-water. After remaining thus for three or four hours the blankets are to be removed, and the patient kept moderately covered. The bath may be repeated on the recurrence of convulsions or any increase in the tendency to coma. In addition to the bath Dr. Breus strongly recommends the administration of the hydrate of chloral given in enemata. In the first of the six cases reported convulsions appeared in the ninth lunar month. The attacks ceased ten days after the use of the baths, and did not return. The patient gave birth to a living child four weeks later. In the second case the convulsion occurred during the sixth month. Similar treatment caused a cessation of the attacks after eleven days, and six weeks later the patient was delivered of a living child. In the third case the convulsions occurred during labor, and continued after delivery. Baths were given, and the patient recovered. In the fourth case the convulsions occurred at the close of labor, and the patient made a good recovery. The fifth case ended fatally on the third day. This patient was, however, comatose when she entered the hospital, and, moreover, had cirrhosis of the liver. In the sixth case convulsions occurred on the twenty-third day after delivery. The patient recovered.

OIL OF EUCALYPTUS IN OBSTETRIC PRACTICE.

Dr. S. Sloan reports [2] the results of his experiments both in hospital and private practice with the oil of eucalyptus as an antiseptic. He had been led to use it owing to his objections to carbolic acid. The latter cannot, he thinks, be used continuously owing to its poisonous action, and the fact that it causes more or less irritation, which prevents a speedy healing of any lacerations. Moreover, he is persuaded that carbolic acid tends to the coagulation of the lochial discharge, thus predisposing to its retention within the uterine cavity. Following the suggestion of Mr. Lister, Dr. Sloan began to experiment with the oil of eucalyptus, and claims that it is not poisonous; that it is a non-irritant when used sufficiently strong to act as a disinfectant; that it does not tend to coagulate the lochia; that it acts as a stimulant to the uterus, causing and maintaining uterine contractions; that its odor is decidedly preferable to that of carbolic acid.

He advises its use in the form of a broad and short pessary applied as near as possible to the os uteri, and there kept in position. The pessaries are made according to the following formula: Oil of eucalyptus, six drachms; white wax, four drachms; cacao butter, four drachms. These ingredients are to be melted together and made into twelve pessaries. One of these should be introduced morning and night. Dr. Sloan does not claim that there is any actual absorption into the system of the oil, but he feels confident that it does freely pass within the uterine cavity. In all hospital cases he has used the pessaries, and in such cases in his private practice as seemed to call for any special antiseptic precautions. He cites, amongst other cases, one of pyæmia, in which the patient was nearly dying when he injected hypodermically five minims of the oil of eucalyptus and twenty minims of olive oil; this was repeated every hour and the patient recovered.

SIGNIFICANCE OF PROLONGED GESTATION.

Dr. Louis A. Rodenstein reports [3] four very interesting cases in which the fœtus was carried in utero longer than the normal period of gestation. He then alludes to the large number of authentic cases, reported by accurate observers, which establish the fact beyond any question, that prolonged gestation is not a myth but a fact. He does not attempt to fix any limit to its prolongation, but insists that the fact that it may be prolonged two months can no longer be questioned. The same principle is involved whether the gestation be carried three days, or, as Professor Meigs has reported, one hundred and forty-five days. After the uterus has physiologically performed its function of gestation for nine months, the proper work of gestation ceases. Why expulsion of the fœtus does not then always ensue Dr. Rodenstein does not attempt to explain, but he believes that the child no longer goes on growing, but lies passive in utero. Were it otherwise, the children would grow to such a size as to render delivery in the usual way impossible; whereas, in the cases cited, the size of the child was normal at the expiration of the prolonged gestation.

A NEW SIGN OF PREGNANCY.

Jorisenne claims [4] to have discovered a new sign of pregnancy. Graves long ago called attention to the fact that in all cases of hypertrophy of the heart the radial beat remains constant, no matter what be the position of the body. Assuming that a hypertrophy of the heart exists in pregnancy Jorisenne has found that, while in health there is a variation of from ten to twenty beats in the radial pulse, according as the body is in an upright or horizontal position, in pregnancy no such change is observed. He advises that the pulse should be carefully counted when the patient is standing, then when sitting, and then when reclining. He has been able to make out the existence of pregnancy as early as the first month by this sign, when the only other symptom was amenorrhœa. His explanation of the reason for this uniformity of the pulse is to be given hereafter.

— A passenger in a sleeping car on an Ohio railroad was injured by the fall of the berth above him and received $6000 damages from the railroad company. The company appealed on the ground that the sleeping car company was the responsible party, but the Supreme Court overrules this point and holds that the railroad company must answer.

Reports of Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.[1]

C. B. NANCREDE, RECORDER.

STAB OF PERICARDIUM, DIAPHRAGM, AND LIVER.

Exhibited by DR. STUTTMATTER.

The specimens were removed from a German laborer aged sixty-two, a patient in the surgical wards of St. Mary's Hospital, under Dr. Mears, who was admitted July 16, 1882. He had been laboring for some days under a mental delusion, and after writing a clear, intelligible letter to his wife and family in Germany stabbed himself with a clasp knife in the right side of the chest several times, notwithstanding all efforts of the bystanders. He was at once taken to the hospital, and on admission was much excited, with a rather flushed face, but little shock, struggling to escape from the punishment of his supposed crime. Examination showed two wounds, one over, and reaching down to the cartilage of the sixth rib of the right side, about one and a half inch from the sternal border, and about two inches in length, the other half an inch from the border of the sternum and severing from it the cartilages of the seventh and eighth ribs. Closer examination of this wound showed that these two openings through the costal cartilages about a line apart, the outer passing downward, outward, and backward, the inner in a direction inwards, downwards, and backwards. Through these openings air occasionally passed when the patient respired violently when struggling, causing a high-pitched sucking and blowing sound. None but slight bleeding took place, and that from the integument. Physical signs everywhere normal except over the lower part of the right lung, where increased resonance was noted, and on heavy percussion a kind of "cracked-pot sound" was elicited. Auscultation revealed diminished breathing sounds over the upper part of the right lung, while respiratory sounds were entirely absent over its lower portion. Heart's action rapid and irregular. Heart sounds feeble, specially the first. Pulse 112, respirations 42 and shallow. There were no signs of internal hæmorrhage. Both during inspiration and expiration when the head and shoulders were raised, and he inspired deeply, a peculiar, high-pitched blowing sound was occasionally heard a little to the left, and below the ensiform cartilage. It did not resemble the sounds produced by gas in the stomach or bowels. Antiseptic dressings were used, and morphia given, but he slept little, although nothing was complained of beyond a burning sensation beneath the sternum. The next morning he was calmer, rational, felt pain only during inspiration, and altogether breathed more easily than during the night, although the physical signs remained the same. The abdomen was tympanitic, the pulse full and moderately strong, 92 per minute; respirations 32, and expiration labored with groaning. Temperature 101.6° F. During the next night grew worse, with restlessness, poor sleep, followed in the morning by cutting pains in the chest at each inspiration, anxious, pinched face, and considerable anxiety as to his condition. Friction sounds were now heard over the whole of the left chest, and on the right side from the apex to the fourth rib. Pericardial friction sounds were also heard. Pulse 100, full and hard; respirations 48, with rapid, jerky inspiration, abruptly terminating, to be followed by a forced, prolonged, groaning expiration; temperature 103.2° F. Evening pulse 120; respirations 44; temperature 103.2° F. During the next twenty-four hours all the symptoms, physical as well as rational, of effusion into the pericardium and both pleuræ developed, but although the abdomen was tympanitic no signs of effusion were detected. Pulse in evening 120, irregular, intermitting; respirations 40; temperature 101.8° F. Had a bad night, and next morning seemed much prostrated, with a feeble, occasionally intermitting pulse of 120 per minute; temperature 102.8° F.; respirations 40, labored and shallow. Low, muttering delirium now set in; he sank rapidly, and died at two P. M. of the 20th, with a temperature of 105.5° F. [The surface temperature record not showing anything of very *decided* interest is omitted.]

Sectio Cadaveris. Brain: pia mater adherent, thickened in patches, and opaque, specially on either side of the vessels, which were filled with dark blood over the upper convex surface of the left hemisphere. There was a slight amount of serous effusion in the subarachnoid space. The ventricles contained a small amount of serum. Chest: on raising the sternum the right pleural cavity was seen filled with a thick, fatty-looking effusion, with some bands of recent lymph extending from the lung to the chest wall. The apex of the lung was quite firmly adherent to the chest wall. The anterior surface of the lung was covered to the depth of one fourth of an inch with soft, grayish-yellow lymph. A portion of the back part of the inferior lobe was consolidated. The left pleural cavity was only about half filled with the same thick layer of lymph and adhesion of the apex that was noted in the right lung. No part of the left lung would sink in water. The pericardial sac was distended with fluid, and both upon its inner surface and upon that of the heart was abundance of lymph connecting the two surfaces by drawn out bands of the same. There was a large chicken-fat clot in the left ventricle, extending about six inches into the aorta. The right ventricle was filled with blood, with a small clot extending into the pulmonary artery. Examination showed that while there were but two penetrating wounds externally, the knife must have been thrust in repeatedly after partial withdrawal, as there were three openings through the diaphragm, penetrating the liver to the right of its suspensory ligament, and one traversing the lower part of the pericardial sac and entering the left lobe of the liver for about one inch. The other liver wounds were one fourth, one half, and one sixth of an inch deep. There were no traces of peritonitis, although about two ounces of serum was present, probably escaped from the pericardial sac through the wound. The liver wounds did not gape, were ununited, and surrounded for about an inch in every direction by a brownish-yellow discoloration. The liver weighed sixty-two ounces. Spleen enlarged and soft; other organs healthy. [Owing to want of space the remarks of Stuttmatter have been omitted, to appear in the next volume of the Society's Transactions.]

Remarks by DR. MEARS. I was much interested in this case. During life the symptoms of wound of the diaphragm and of the liver were markedly absent, whilst those of injury of pericardium and pleura developed as the interval after the receipt of the wounds increased. The external wounds gave little indication as to the direction taken by the knife after puncturing

[1] Concluded from page 14.

the thoracic cavity, and, as shown by the post-mortem examination, no information as to the extent of injury inflicted. The absence of symptoms of injury of the diaphragm may be explained by the fact that the wounds were in the tendinous portion of that muscle, and being small did not interfere to any great extent with its function in respiration. In injuries causing laceration of the muscular fibres attached to the ribs dyspnœa occurs as a prominent symptom by reason of the impairment of the respiratory duty of the muscle. Moreover the symptoms may have been masked by those referred to the injury of the pericardium, as in wounds of both of these structures dyspnœa is a prominent symptom. The knife, in one of the thrusts, passed through both, and involved them in a common injury. The only explanation I can offer of the production of the blowing or rather suction sound which was heard under the ensiform cartilage is that it was occasioned by the passage of air during inspiration through the openings in the diaphragm, the air entering primarily the lung cavity through the external wound. The fact that the air did not pass in and out of the external wound during the act of respiration afforded good evidence that the lung was not wounded. The wounds of the liver were of such character as to make little or no impression beyond what might occur as the result of injury to the coverings and superficial portions. Puncture of the liver with a trocar is frequently performed with a view of evacuating fluids. Instances are reported in which no fluid has been found, and no harm has been inflicted by the tapping. Extensive lacerations, the result of gun-shot wounds or ruptures following falls, produce characteristic symptoms of shock and internal hæmorrhage.

SECONDARY SARCOMA OF HEART, LUNGS AND GALL-BLADDER, FOLLOWING PRIMARY AMPUTATION FOR DEPOSIT IN THE FEMUR.

Presented by DR. WILLARD.

The specimens exhibited were the heart, lungs, and gall-bladder of a female patient, aged twenty-one, whose right thigh had been amputated four months previously for a spindle-celled sarcoma of the lower end of the femur. The apex of the right ventricle was infiltrated with a sarcomatous mass which extended into a cavity among the columnæ carneæ, forming an irregular-shaped body occupying one fifth of the space. The walls were softened, and but little of a muscular fibre was to be seen at the apical region. The diseased tissue was very soft, and easily detachable, rendering its propulsion into the lungs a matter of exceeding probability at each heart beat. The walls above the mass were natural in appearance and in thickness, the valves showed no evidence of disease on either side of the heart. The left ventricular and both auricular walls were healthy. The disease had not reached the visceral layer of the pericardium, and there was no abnormal effusion in the cavity of the sac. The septum ventricularum was not involved. That numerous particles had been swept into the lungs was very evident when these organs were examined. At a large number of points in either lung were to be seen white masses varying in size from that of a pin's head to that of an English walnut. Some of these were dense, others were undergoing softening, and in nearly every instance the lung substance surrounding was so disintegrated that the mass seemed to be in a cavity containing a dram or more of sanguinolent fluid. A very moderate degree of pressure would cause a nodule near the surface to burst its pleural covering, and give rise to an accident similar to the one which was found to have occurred near the right apex. At this point a large sarcomatous mass had excited a degree of inflammation sufficient to fasten the lung to the parietal pleura, and one week before the patient's death ulcerating through the serous covering had given rise to an internal hæmorrhage that was well-nigh fatal, and gave the symptoms of sudden collapse noted in the history. This escaped blood was found in the right pleural cavity confined by adhesions chiefly to the upper portion of the chest. In the week which elapsed between the hæmorrhage and death it had coagulated, formed chicken-fat clots and other coagula weighing fully two pounds. The pleural cavity below the adhesions contained about two quarts of bloody serum. There was no consolidation of the lungs save around the diseased foci. The lungs had evidently acted as a complete strainer, and had prevented the passage of emboli, for liver, kidneys, spleen and all other organs were healthy, save one small spot in the gall-bladder. The brain was not examined. The primary disease in the femur had apparently resulted from traumatism, since no difficulty had existed previous to a severe fall upon the knee. From this time the pain on walking was continuous, and four months later there was decided enlargement of the external condyle and swelling in the popliteal space. The chief points of interest in the case were: First, The traumatism acting as an exciting cause. Second, That the physician who first saw her detected neither fracture, nor luxation, nor anything beyond contusion of the joint. Third, The appearance at the end of four months of a pulsating tumor in the popliteal space, which presented a decided bruit but no thrill. This was due to the lifting of the artery from its bed by the sarcomatous mass. Fourth, The non-involvement of the knee-joint, although the nodules had pushed forward the synovial membranes between the condyles posteriorly. The articular cartilage of the femur was intact, although the bone tissue immediately beneath it was extensively diseased. Fifth, The return of the disease, not in the stump but first in the right ventricle, leading to failure in circulation and great prostration, which came on from four to six weeks after the amputation and without anything in the condition of the stump to warrant such depression. The patient seemed in articulo mortis, yet there was no pain and no dyspnœa, only a feeble, rapid heart action accompanied by low delirium and weakness. There were no valve sounds audible. These symptoms were due, as shown post mortem, to the deposit and development of the sarcomatous mass in the heart. Nature, however, gradually accommodated herself to the new growth, and the patient rallied for a time, so as to be able to walk on crutches, eat heartily, and consider herself in good health. She got fatter, and only slight dyspnœa on exertion, with three or four coughs a day, remained to indicate recurrence of the disease. Sixth, A sudden, causeless as to exertion, profuse hæmorrhage, from the collapse incident to which she rallied and lived one week, with respirations 30–36, pulse 130–140. Seventh, The primary and consecutive growths showed a preponderance of spindle cells, while the secondary nodules were composed chiefly of round cells. Eighth, The post-mortem examination throws great light upon the clinical symptoms, while the great rarity of sarcoma of the heart makes it important to note that there was never any angina pectoris.

In Dr. Ingram's report of a case called carcinoma of the heart, in the Transactions of this Society for 1877, the only case ever presented to this Society, angina pectoris was indicated as one of the diagnostic points. In the report of the Committee on Morbid Growths Dr. Ingram's specimen was shown to be really an alveolar sarcoma. Secondary sarcomatous growths of the heart are mentioned by various authors, but the histories give no clinical signs of the growths.

DR. BARTON said that in regard to traumatisms causing morbid growths he considered that they probably had no more causative effect than acting as exciting causes.

DR. FORMAD asked if the exact nature of the primary growth was known, whether it consisted of round or spindle cells, since it has been stated that the spindle-celled variety never forms metastases.

DR. SEILER replied that the primary growth consisted of both round and spindle cells.

DR. SHAKESPEARE agreed with Dr. Barton as to the origin of the primary growth. He did not believe that injuries were anything more than exciting causes in those predisposed to such growths. The case presented a typical example of the method of metastasis; we have the growth first developing at the knee, whence particles are carried by the veins to the heart, become there lodged, and develop into a tumor, which forms a new centre from which microscopic emboli are carried by the blood-current into the lungs, where they lodge and grow into the nodules seen in the specimen. Metastasis of sarcoma occurs by means of the blood-current, while that of carcinoma takes place through the lymphatics.

DR. FORMAD could see no other cause for the tumor than the injury of the knee, previous to which the patient had never shown any symptoms of disease of the joint, while shortly after receiving the injury the tumor appeared. The tumor may not necessarily be malignant; there is an inflammation and the formation of cells; the malignancy will depend upon the looseness of the cells and the facility with which they can be transported.

DR. C. K. MILLS then read a paper on The Brain in Epilepsy, which, not admitting of abstraction, will be shortly published in full.

DR. BRUBAKER presented a specimen of Tumor of the Brain, which, with the accompanying paper, was referred to the Committee on Morbid Growths, whose report, with the paper, will appear at some future time.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

DECEMBER 11, 1882. DR. J. C. WARREN presided.

LIPOMATA.

DR. JOHN HOMANS read a paper on Two Cases of very Large Fatty Tumors within the Abdomen.

DR. ELLIOT remarked that he had the pleasure of assisting Dr. Homans in this operation; that it seemed especially interesting to him on account of the immediate recovery in spite of the fact that some of the contents of the bowel escaped into the abdominal cavity. Dr. Homans thinks that patients usually recover from the operation of making an artificial anus. If so, why would it not be a good operation in cases of cancer of the intestines to pull up the diseased part of the bowel, which is often only a small annular nodule, and sew it to the abdominal opening in such a manner that the disease should be left wholly outside the abdomen? If it did not slough off it could be removed later, and then the fistula might be closed. It seemed that in this way we could often remove cancer of the intestines more safely than by resecting a part of the gut.

DR. M. H. RICHARDSON said that he had had the opportunity of assisting at both operations in the first case reported, and it had seemed to him a remarkable triumph for modern abdominal surgery that the patient had survived the exploratory incision. Merely to replace the tumor had required all the strength of the assistants, and sewing it in seemed at the time a matter of form.

To those who had seen some of the previous operations of Dr. Homans, in which no idea of recovery had been entertained by any one, and yet in which convalescence had been rapid and recovery complete, the condition of this patient did not seem hopeless except for the fact that the mesentery had been entirely removed from the colon for a considerable distance. It is a well-known fact that when the intestine is deprived of its mesentery to any extent mortification ensues, the anastomoses being too remote for the establishment of sufficient collateral circulation.

DR. GANNETT thought that it would be very difficult, if not impossible, to remove such large retro-peritoneal tumors, even by enucleation, without separating portions of the meso-colon from either ascending or descending colon. In such a case the probability of necrosis of the isolated intestine was evident.

DR. HOMANS also spoke of a case on which he had recently operated, where he supposed from the preliminary examination that he had to deal with fibroids, but on operating he found the tumors to be ovarian; both ovaries were removed, and he had no idea that the woman would get well, but she has recovered completely.

DR. FITZ asked if any successful cases of the removal of these myxomatous tumors had been reported.

DR. HOMANS replied that he had never heard of any.

MEMBRANE FROM INTESTINE.

DR. GOSS showed a specimen of membrane-like discharge from the bowels of the patient referred to as Case I. in the paper on A Membrane-Like Affection of the Bowels, read before the Society in May, 1881. Since the paper was read until recently the patient has had but slight return of her trouble. The history of the present attack is as follows:—

Some three or four weeks ago Mrs. A. began to have feelings of general malaise, thought she was feverish, though the thermometer showed hardly any elevation of temperature. She had smarting of the eyelids, and smarting and dryness of the throat, then similar sensations under the sternum, followed by a burning and gnawing feeling at the stomach. These discomforts, to use her expression, "as though the mucous surfaces were generally affected," continued for several days, when, for three or four days, she had each day, following an injection of olive oil, a single evacuation of the membrane-like discharge, varying from one half to a whole teacupful in amount. There was scarcely any fæcal matter passed during this time. The evacuations were followed by a sensation in the hypogastric region, lasting for an hour or more, "as

though the bowels had been scraped." During the succeeding ten days the membrane-like discharge was less abundant, and the fæcal matter larger in amount. During the past week there has been but little of the peculiar discharge.

STENOSIS OF THE LARYNX.

DR. HOOPER spoke as follows: —

"I present this case of stenosis of the larynx as one in which the treatment by Professor Schrötter's ingenious method of mechanical dilatation has been followed by the happiest results. The patient has quite a remarkable history. He is a Roumanian by birth. Arriving in this country last Friday, he turned up at the Massachusetts General Hospital the same day. My acquaintance with him, however, is an old one, for during the many months I attended Professor Schrötter's clinic in Vienna, three winters ago, he was in the ward under daily treatment. He is twenty-eight years of age. In the winter of 1877, while traveling in Roumania, he and his companions were attacked by a band of robbers. His comrades were all killed. He himself was hanged to a tree, and subsequently left in the snow for dead with his throat cut, and three large stabs in the abdomen. Remaining on the ground for forty-eight hours, he was finally discovered and taken to Jassy, the principal town in Roumania, with frozen feet in addition to his other troubles. So runs the patient's story. Schrötter always affirmed that he was himself a robber and a cut-throat, and one of the greatest scoundrels of the century. Be this as it may, it is certain that when he first came under Schrötter's inspection, in June of the same year, the larynx was completely occluded by cicatricial tissue at a point superior to the external cut, and just below the vocal bands. Schrötter, operating through the mouth, divided the stricture with his laryngeal bistoury, and then employed his instrument for dilating the larynx.

"I am very glad to have this opportunity to show the instrument and the method of using it, for certainly the profession is indebted to Professor Schrötter for the treatment of this important class of cases. The instrument consists of special graduated plugs, made of tin or lead, of the triangular shape of the glottis, and with rounded edges. A brass rod passes through the centre of the plug, with an eye above for affixing a string, and a knob below for retaining it in position by means of a bolt inserted through the tracheal canula. When the plug is to be introduced into the larynx it is attached to a special canulated laryngeal director by means of the string passing through the tube. This tube is withdrawn as soon as the plug is retained in position by the bolt, whilst the string, which is left protruding from the mouth, can be tied round the ear. To withdraw the plug it is merely necessary to remove the bolt from the canula, and pull the plug up from the larynx by the string. This patient has now not only sufficient room for breathing purposes, but he has a remarkably good voice. He is interesting from another point of view, inasmuch as by looking through the external opening into the larynx the closure of the glottis during deglutition is very prettily shown."

DR. FIFIELD read the following paper: —

IDIOPATHIC ENDOCARDITIS.

M. C., aged seven years, had always been tolerably healthy, and had never had either rheumatism or chorea. She was descended from very strong, robust parents, neither of whom has ever exhibited the slightest tendency to rheumatism. When first seen, November 7th, she had a rapid pulse of 120 per minute and a temperature of 104° F. No cough or pain complained of, and but for the rapidity of the pulse and the elevated temperature would not have been considered very ill, as she sat up in bed and played with her doll, and was as much interested in the affairs of the family as ever. It was the temperature of 104° F. that induced me to examine the chest, half expecting to find a commencing pneumonia. With the exception of a patch of coarse breathing at the base of the left lung, and a very little dullness on percussion, nothing definite could be found so far as regarded the lungs. But I did hear all over the left side of the chest posteriorly a loud, well-marked bellows murmur, such as one might expect to find in a case of aneurism of the aorta. This loud murmur was found to proceed from the region of the mitral valve, and to be a regurgitant one, so loud and strong that it made itself heard all over the left chest. Together with this murmur I fancied that I heard a soft to-and-fro friction sound from the pericardium. With all this no irregularity of the pulse, not even the paradoxical one, keeping time with the respiration, which has so often been spoken of as a diagnostic of acute pericarditis. The treatment ordered was the application of three large leeches over the heart; four drops of tincture of digitalis every fourth hour; three grains of carbonate of ammonia every fourth hour. Milk and lime water diet. On the 8th she seemed somewhat better. Had rested well, and seemed to have no dyspnœa. Pulse 120. Temperature 102.8° F. The disease ran on with but little variation, excepting that all trace of the to-and-fro rub disappeared, if there had ever been any.

Although up to this time I had not been able to find in any author, English, French, or German, any allusion to idiopathic endocarditis as evidence of rheumatism *per se*, so strong was my conviction that at one time I changed the treatment to that of salicylate of soda, three grains every two or three hours, but was glad to run back to the treatment first adopted.

On the 20th the child seemed rather worse, refused a good deal to take her drinks, requiring persuasion. The mother reported her nights as bad, sleepless, complaining bitterly of pains running down her arms. The temperature was nearly the same, — 103° F. in the afternoon; pulse 120 to 130; respiration quicker. Still not the slightest evidence of rheumatism. If she had pain at night she always denied having any by day. It seemed to me, however, that the area of dullness over the heart's region had extended, and I summoned Dr. Rotch to my aid. Dr. Rotch will perhaps tell you better than I can that whilst he did not find the line of dullness reaching over the border of the sternum to the right, as would be expected, had there been any large amount of fluid in the pericardium, he *did* find the area of dullness increased to the left, indicating to him the presence of dilatation. I understood him to express a belief that the murmur was a regurgitant one. Nothing marked on the part of the lungs. I should have mentioned that I had examined the urine, but found nothing abnormal in it.

Both Dr. Rotch and myself, while acknowledging the extreme gravity of the case, had some hope of a favorable termination, so far as preservation of life was concerned. No change of treatment was made, but

from this day forward the little child failed. She refused all nourishment and stimulus; turned against her powders of ammonia and her drops; vomited very frequently; pulse raced faster; breathing became more and more hurried; tongue dry and parched; though with all this she sat bolstered up in bed, regarding all that went on with an observant but undismayed look, always ready to speak pleasantly and cheerfully. On the night of the 24th I found her still sitting up, brave as ever, though her lips were purple and her hands wet with the dew of the fast advancing sunset of life, pleased with some flowers I had brought her, and dying at midnight still holding some rose-buds in her hand.

In the course of my life I have seen two cases of acute endocarditis unaccompanied by any rheumatic affection; also one case of endocarditis with pericarditis, and one case of pericarditis, both equally free from rheumatic complication. The first case occurred some twenty years ago in a young child, perhaps five years of age. This case was seen in consultation with Dr. H. I. Bowditch, and so completely recovered that to-day in the young lady I am unable to detect any murmur whatever indicative of diseased heart. The second case was a young boy recovering from scarlet fever. This, too, went on to a favorable end, and now in the tall, strong young man I find nothing amiss with his heart. The third case, endo- with pericarditis, I saw some months ago in consultation in Quincy. A boy, perhaps nine years of age, who nearly eighteen months since had scarlet fever, followed by dropsy and albuminous urine, but was supposed to have fully recovered, being able to run and play with his schoolmates as well as the best of them. Here the friction rub was distinct, and beyond and above it was heard the mitral murmur. The boy's urine contained albumen in considerable quantity when I saw him. His treatment was leeches to the region of the heart, digitalis internally. He recovered well.

The fourth was a case of pericarditis reported, I believe, to this Society by Dr. Edes, together with a report of the autopsy. In this case I found, for the first time, the paradoxical pulse, first described, I think, by Kussmaul.

In no one of these cases did any rheumatic symptom make its appearance.

In August, 1882, Dr. Alfred J. Harrison read in the Section of Medicine, at the annual meeting of the British Medical Association, a paper entitled Primary Endocarditis. Dr. Harrison strikes his key-note at the very start (and I believe many physicians will be in full accord with him) by saying: "The subject of endocarditis is of primary importance in more senses than one. For a long time I have felt that endocarditis is of more frequent occurrence than is generally supposed, and I have often found during the examination of people apparently healthy, for life insurance and other societies, that slight abnormalities existed in the sounds of the heart, which made one incline to believe that there must have been at some time or other endocardial inflammation; and I now feel sure that many of these people had suffered from endocarditis without being aware of it. Many authors make allusion to endocarditis as a probable idiopathic disease, yet no one, so far as my knowledge goes, has ever recorded an actual case, with the exception of M. Barth, who, in *La France Médicale*, gives one, of intra-uterine fœtal origin." Dr. Harrison then proceeds to narrate three cases, two of them in his own house, and he speaks of a fourth still under treatment. Of these cases he says that the first had a marked symptom of rheumatism, namely, acid perspirations. The second was a case of endocarditis without any apparent rheumatic complication. The third had no rheumatic complication whilst under my care, but shows the results of it in a diseased heart; and now I can add a fourth also free from any rheumatic symptoms, unless the endocarditis be one form of rheumatism. Dr. Harrison's first case was that of a lad aged fifteen years, recovered; the second, his own son, fifteen and a half years, old, recovered; the third, a book-binder aged twenty-five years, recovered; the fourth, that of a girl thirteen years old, also recovered without having had a trace of rheumatism. Dr. Harrison remarks: "I have no doubt I have seen three of these cases during an attack of endocarditis, or if not endocarditis, what has it been? and I cannot help giving an opinion that it is quite possible to have an acute endocarditis, or rather, as I am inclined to put it, without any other symptom of rheumatism. I attach great importance to the salicylate treatment when it can be carried out."

Dr. Clifford Allbutt said that endocarditis was not infrequently the first and solitary event, perhaps, of acute rheumatism.

Dr. Balfour, of Edinburgh, wished to point out that they ought not to consider that every case of systolic murmur was one of endocarditis, that one might even have a certain amount of rheumatism with a systolic murmur without endocarditis. He had *never* seen any case of rheumatic fever in which one could not detect a systolic murmur. Pericarditis was a much more common thing than any one was at all aware of. But there was another note of warning that he wished to give, and that was not to regard every case of friction as a case of pericarditis. Influenza was often associated with, or rather resulted in, endo- and pericarditis.

In October, 1882, Dr. Robert Saundby, of Birmingham, published in the *Birmingham Review*, recently copied into the *New York Medical Abstract*, two cases of pericarditis.

His first case is given as one of pericarditis, endocarditis, pulmonary infarction. Pericarditis supervening in the course of chorea. No previous history of rheumatism; rheumatism in family. Recovery after blistering, and return of chorea. Relapse and death. The following is an abstract of the case:—

Florence K., aged eight years, had had scarlet fever and measles, and for a month before admission had been suffering from chorea. One of her sisters had had rheumatic fever three times, and one brother had had it once. When examined, September 2, 1881, he found a pale, sickly-looking girl, sitting up in bed, breathing rapidly, 45 to the minute, feeble pulse, 132. Temperature previous evening 103° F., but had fallen to 101.6° F. Limited patch of tubular breathing and crepitation at the lower angle of the left scapula. Heart's apex one inch external to the mammillary line. Over the apex a loud double murmur, the systolic portion being propagated in the direction of the axilla, and audible at the inferior angle of the left scapula. Three days later there was over the cardiac area, in addition to the previously described sounds, a distinct to-and-fro friction murmur. By the 9th physical signs of pneumonia had disappeared; pericardial friction unal-

tered. Blisters applied. 10th. Friction less; by the 12th had disappeared, except at one spot over the third costal cartilage. 14th. All friction had disappeared. 17th. A rough systolic murmur audible over the third cartilage, thought to be exocardial. Patient's general health continued to improve. 21st. This murmur had disappeared, and choreic movements had noticeably increased. 26th. Much better, and sat up in the afternoon. 28th. Remained in bed and began to be troubled with a teasing cough. 29th. Very pale but sitting up in bed complaining of her heart. Heart's action tumultuous, but no friction. 30th. Temperature 101° F., respirations 84; began to vomit. October 1st. Vomited frequently, restless, coughed up bloody froth. 7th. Feet began to swell. Died on the 8th.

Autopsy showed pericardium generally adherent. Adhesions soft and recent. Several patches of endocarditis, and both mitral and tricuspid orifices studded with vegetations. Slight pleuritis on right side, and scattered through the right lung were several dark-red, firm, tough patches, which sank in water. In the left was a similar patch.

Here the pericarditis was justly considered rheumatic in origin, for although she had not had it herself the family tendency was strong. Evidently, too, she had had endocarditis for a considerable time, possibly following the attack of scarlatina. When admitted she had a limited patch of pneumonia, set up probably by a hæmorrhagic infarction, of which so many were found in the lungs after death. The influence of blistering in procuring some improvement in the physical signs of pericarditis was very evident, but this proved very ill-founded, and the appearances at the autopsy made it difficult to understand how she could have appeared better even for a day or two. There was evidently a second attack of pulmonary infarction; this time in the right lung, and the cardiac muscle began to give way. The post mortem showed that this was œdematous and infiltrated with leucocytes. It is this condition that really constitutes the danger of pericarditis; the mechanical effects of the effusion, as Stokes wisely said, are too much exaggerated, while the true danger from the softened and inflamed myocardium is very imperfectly recognized.

CASE II. Man, aged twenty-three years. When examined, the day after admission, September 6th, temperature 101° F., pulse 102, respirations 24. Physical examination showed soft, double friction murmur, loudest over the fourth left interspace. All other organs normal. On 9th the friction was more audible. Blistered. That evening temperature rose to 103° F., but fell in the next twenty-four hours to 100° F. On the 12th friction diminished. On 14th only a slight, soft murmur. 17th. Pulse irregular, only 50 per minute. It appeared that he had been out of bed at the water-closet. After rest the pulse rose to between 80 and 90. On 21st heart intermitted regularly every fifth or sixth beat, then suddenly changed and went quite regularly. He continued to improve, and was discharged on October 6th. Seen again on the 20th, when the heart sounds were quite normal.

This case was one that would be called by many idiopathic pericarditis. Walshe said some years ago that "alleged idiopathic pericarditis becomes rarer every year in proportion as the evolution of diathetic diseases grows more fully understood," and added, "I have never yet seen a positive case of the kind." Yet early this year Dr. Walter G. Smith related three cases of idiopathic pericarditis at a meeting of the Medical Society of the College of Physicians, Ireland, and maintained that they had occurred independently of any injury, or other local cause, or of extension of inflammation from neighboring parts, or of any relationship to rheumatism, chorea, exanthemata, renal disease, pyæmia, tuberculosis, or the puerperal state.

"I should, therefore, be inclined to admit that this case was idiopathic, if I did not believe that rheumatic pericarditis may occur by itself without giving rise to the general phenomena of rheumatism."

PROCEEDINGS OF THE MONTHLY PHARMACEUTICAL MEETING OF THE MASSACHUSETTS COLLEGE OF PHARMACY.

B. F. DAVENPORT, M. D., REGISTRAR.

THE U. S. PHARMACOPŒIA.

AT the regular meeting of December 12th a series of *seriatim* discussions of the subject of each title of the new revision of the U. S. Pharmacopœia was begun, which are to extend through the meetings of this season.

There was a general expression of approval of this revision as a whole, very complimentary remarks being made concerning Dr. Charles Rice, of New York City, chairman of the committee, to whom much of the credit is due. Regrets were, however, expressed that it had made no provision for being generally considered to have gone into full effect at some specific date, such as on January 1, 1883, in order to have removed any lingering doubt in the minds of any as to whether the prescriber was to be considered as having intended or the dispenser was to be expected to put up on any recipe the preparations made according to the 1870 or the 1880 revision. In such cases as with tinct. opii there is a difference of fifty per cent. in that made according to the two revisions.

In renewals of recipes dispensed before the appearance of the new revision was the pharmacist to put up tinct. opii according to the old or the new revision, after the latter had come into general use. After what date was the drug analyst under the new Adulteration of Food and Drug Act to deem as adulterated within the meaning of that act preparations which did not conform to it in strength, quality, or purity. Under the present circumstances it would seem that, as there cannot well be but one legal U. S. Pharmacopœia, the new revision must be considered upon its first appearance to have superseded the old. Here, however, as in all cases of doubt in dispensing in the mind of the pharmacist as to what was the intent of the prescriber, that should first, if possible, be removed before the recipe is put up. If, however, that cannot be done, he should either decline to dispense at all, or else put up according to the apparent call, that is of the new Pharmacopœia, informing, however, the presenter of the recipe of the nature of the doubt, thus freeing himself from all possible responsibility, but throwing it back upon the physician, where it naturally belongs, as he should so write his prescriptions as to leave no such doubt. Pharmacists, however, who for any reasons should hereafter sell a preparation made according to the old revision of 1870 should protect themselves by labeling it U. S. P. 1870. It would seem that all renewals of

old recipes should be exact renewals thereof unless the change to the new preparation be sanctioned by the prescriber.

The new class of official preparations, the abstracts, were well thought of, although not at present frequently prescribed in this vicinity.

THE NEW YORK ACADEMY OF MEDICINE.

ELECTION OF OFFICERS.

An election of officers occurred at the Academy of Medicine Thursday evening, January 4th, which resulted as follows: President, Dr. Fordyce Barker (reëlected); Vice-President, Dr. H. P. Farnham; Recording Secretary, Dr. W. H. Katzenbach; Corresponding Secretary, Dr. J. G. Adams (reëlected); Treasurer, Dr. William F. Cushman; Trustee, Dr. Gouverneur M. Smith (reëlected); Treasurer of the Board of Trustees, Dr. Charles Wright (reëlected); Member of the Committee on Admissions, Dr. E. L. Partridge; Member of the Committee on Ethics, Dr. H. E. Crampton; Member of the Committee on Education, Dr. John C. Dalton; Member of the Committee on Library, Dr. A. McLane Hamilton. On this occasion the reports of the various committees were read, and in that of the Committee on the Library it was stated that the Academy now owned more than nineteen thousand bound volumes, and five thousand pamphlets. During the year the library and reading-rooms had about four thousand visitors.

The paper of the evening was by Dr. F. H. Bosworth, on the subject of Tumors of the Nasal Passages, and it was discussed by Drs. Lefferts, Beverly Robinson, and Lincoln.

Under the popular presidency of Dr. Barker the Academy has steadily advanced in prosperity, its library has received constant and valuable accessions, and the semi-monthly meetings have been well attended, and usually of considerable scientific interest.

Recent Literature.

A System of Human Anatomy; including its Medical and Surgical Relations. By Harrison Allen, M. D., Professor of Physiology in the University of Pennsylvania, etc. Section I. Histology, by E. O. Shakespeare, M. D. Section II. Bones and Joints. Philadelphia: Henry C. Lea's Son & Co. 1882.

The appearance of the book, the first two parts of which are before us, marks an epoch in medical literature. It is the first important work on human anatomy that has appeared in America, and more than this its scope is new and original. Let the author speak for himself: "Works on anatomy may be placed in two groups: Those written by scientists which have no special application of any kind, and those written by surgeons which have a decided leaning to surgical application. . . . It requires but little discernment to detect the faulty plan upon which both these varieties of books are constructed. The scientist necessarily lacks clinical knowledge and sympathy; the surgeon lacks interest in all but one class of subjects." Though thinking this saying a little severe we are quite ready to admit that there is room for a serious work on a new plan, and to cordially welcome the one Dr. Allen has given us. It is intended to be both descriptive and topographical, scientific, and practical, so that while satisfying the anatomist it will be of value to the practicing physician. A novel feature in the book is the discussion of the effect of the structure of special parts or regions on diseased action within their limits, which will be emphasized by the reports of apposite cases. Histology, normal growth, monstrosities, and variations are all to be treated of. Such a work is certainly novel, and if the execution equal the conception it will bring the greatest honor to the author.

The section on Histology is by Dr. Shakespeare, who is well known as of merit in this branch of science, and the winner of the Warren Prize a few years ago. We have noticed nothing particularly original in it, but it is well written, up to times, and satisfactory. It is well illustrated by wood cuts in the text, and by twelve full page beautifully colored lithographs. Most of the figures are not original, but as they are good this is no defect; but we are absolutely astonished at the incomprehensible way in which perhaps half of them are credited to the wrong authors. Thus we find a large number of very familiar figures ascribed to Gray or to Carpenter, who are as innocent of having made them as Dr. Shakespeare himself. This is the more extraordinary as in the preface to the eighth edition of Gray it is honestly stated that illustrations "have been borrowed with permission from well-known text-books, such as Frey's Histology, Stricker's Handbook, and Quain's Anatomy." Moreover, when a figure that first appeared in Stricker's Handbook escapes being given to Gray or Carpenter it is, we believe, invariably given to Stricker instead of to the author who wrote the chapter in the Handbook, and to whom of course the credit belongs.

The second section, on Bones and Joints, is, of course, by Dr. Allen himself. The introductory general remarks on bones are very satisfactory and comprehensive. Among other subjects discussed are the peculiarities of the living or fresh bone, the identification of bones, bones as mechanical agents, the causes of variations in their shape, and the way in which the shape may be modified by diseased action. The causes of variations of shape within normal limits are twofold; the vascular supply and muscular action, concerning both of which there are interesting remarks. The vertebral column is then taken up; first a brief description is given of some of the essential parts of a vertebra, and then, before the systematic description of the vertebræ, the column is considered as a whole. The mechanics are carefully studied both in their normal and pathological relations. The description of the various bones of the skeleton is marked by its unconventionality, the main features are clearly pointed out in few words. The utter absence of even the appearance of pedantry, which we have come to think almost inseparable from anatomical work, is very refreshing. The internal structure of the bone receives attention as well as the outside, and this is, we believe, a new feature in any of the larger anatomical treatises. The description of each bone is followed by remarks on its variations, and on the pathological processes or accidents to which it is particularly liable.

The characteristic features of the descriptions stand out especially in the treatment of the bones of the

skull. The temporal bone is described in a way that will appear even startling to those conversant only with English works. We are surprised that Dr. Allen acknowledges only one temporal ridge, though parts of two are distinctly shown both in the drawing of the parietal bone and in that of the side of the skull. The innominate bone is also treated in a new manner. We suppose it is by inadvertence that the tendon of the obturator internus is said to pass through the great sciatic notch, and we should say the same of the statement that the superior and inferior gemelli both arise from the spine of the ischium, were it not that the places of their origin are so represented in the plate also. There is a passage in the description of the clavicle which we fail to understand, and which seems to us quite inaccurate. "Stretching across the under surface of the body from the conoid tubercle in front to the posterior and inferior border, is an oblique line that limits the surface of origin of the pectoralis major muscle inferiorly." Now as the conoid tubercle is on or near the posterior border, and as the pectoralis does not extend nearly so far outward, we not only cannot admit the statement, but we cannot conceive what clerical or other error is at the bottom of it. The illustrations of the bones are very fine. The names of the parts, muscular attachments, etc., are printed either on the figure or close beside, so that they are easily recognized. Perhaps many of the figures are too much shaded, by which they lose in clearness. A more serious criticism must be made against the drawings of some of the long bones, which are shortened out of all proportion, apparently to make them fit into the plate.

The chapter on Joints begins also with an excellent discussion of the subject, embracing many interesting considerations, such as the influence of atmospheric pressure and the development of joints. Dr. Allen's classification differs a good deal from the usual one. There are, according to him, four chief divisions of joints. *Sutura* includes the union of bones arising from membrane, and *Synchondrosis* that of those arising from cartilage. *Symphysis* includes the union by fixed fibro-cartilage of bones which are without incrusting cartilage, and *Diarthrosis* includes joints with incrusting cartilage and synovial membranes. According to this plan, the so-called sacro-iliac synchondrosis and the joints between the bodies of the vertebræ are to be reckoned symphyses. We are not prepared to say how this nomenclature will stand the test of experience. It is hard to accept a new meaning for a term with which we are already familiar, but we are thankful for any change that will free us from the complicated system replete with jaw-breaking names now in use. We have no space to discuss in detail Dr. Allen's treatment of the joints; suffice it to say that it is admirable, and that any criticisms we might make would refer to very trifling points. It seems to us, indeed, that not enough is said about motions, but probably this want will be made good in the section on muscles.

The illustrations of the joints made from the author's dissections deserve the highest praise. They bear witness to his skill with the scalpel, and to that of the artist with his pencil. They are well conceived and well executed, handsome artistically, and clear anatomically.

We trust the reader who has followed us so far will have gathered that there is a great deal in this work that to receive justice requires much more space than we can give to it. As the author points out, such a work as he has undertaken is necessarily encyclopædic, and the result shows that he has brought to it a mind well prepared for the task by extensive reading, critical judgment, and literary ability. We can cordially recommend the work to the profession, believing that it is suited not only to those of scientific tastes, but that it will be of use to the practicing physician. On the other hand we must wait till more of the work has appeared before expressing any opinion as to whether it should supersede the works now in use for students who are beginning their studies. Advanced students may certainly profit by it. The sections of the book appear in neat covers, and the type and paper are handsome. T. D.

The Chamberlens and the Midwifery Forceps. Memorials of the Family and An Essay on the Invention of the Instrument. By J. H. AVELING, M. D., F. S. A. London: J. & A. Churchill. 1882.

The writer of this biographical sketch has been collecting materials relating to the Chamberlens for ten years, he tells us, and yet it is only quite recently that he has mastered the subject and dispelled from his mind the confusion caused by there being three Peters and two Hughs. He warns the profession against accepting as true any account of the Chamberlens published before this date, no matter how trustworthy in other respects the author may be.

Dr. Peter Chamberlen, hitherto regarded as the inventor, or rather re-inventor of the forceps, Dr. Aveling believes to have no claims to this distinction, his uncle Peter Chamberlen the elder, who came to Southampton from Paris as a child with his parents, about 1570, being the real inventor.

Much confusion has arisen from the fact that Dr Peter Chamberlen's father and uncle were, curiously enough, both named Peter, the former being known as Peter the younger and the latter as Peter the elder.

A Manual of Hypodermatic Medication. The Treatment of Diseases by the Hypodermatic Method. By ROBERTS BARTHOLOW, M. A., M. D., L.L. D. Philadelphia: J. B. Lippincott & Co. Fourth Edition. 365 pages.

In the first few pages the history and the local and systemic effects of subcutaneous injections are briefly considered, the latter in a very practical way. It is probably too late to succeed in substituting "hypodermatic" for "hypodermic;" subcutaneous is sufficiently good.

Most of the work is devoted to the action and uses of numerous drugs which may be used subcutaneously. Among them morphia and atropia, together with their physiological antagonism, and the treatment of the opium habit, receive most attention, more than one third of the book being given to them. Among more than thirty drugs the proper form of solution, the physiological action, and therapeutic uses of pilocarpine, ergotin, digitalis, salts of quinia, mercury, strychnia, iron, chloral, chloroform, and ether are given.

Like all of Professor Bartholow's writings this one is interesting and instructive. There is no better work on the subject. As a manual it would have greater value if it were smaller.

Microscopical Morphology of the Animal Body in Health and Disease. By C. HEITZMANN, M. D. With three hundred and eighty original engravings. New York: J. H. Vail & Co. 1883.

A work by a microscopist of Dr. Heitzmann's reputation will be sure both to deserve and to attract attention, especially when it is understood that it shows normal and morbid histology in the light of his original theories. The book contains several chapters that have appeared before as separate articles both in English and German, and some chapters are written by other observers. Still Heitzmann's spirit informs the whole. We are a little amused at his way of quoting complimentary passages from the works of his friends and pupils. We must beg leave to present to our readers rather a long passage from a paper by Dr. Elsberg, which, while it gives a good idea of the author's views, is a striking instance of the peculiarity we refer to: —

"It is the merit of Heitzmann to have discovered, in the first place, that the living matter in its simplest form, as seen in an amœba, the so-called basis matter of life, to which hitherto the name of protoplasma has been applied, but which I propose to designate as bioplasson, is not without structure, as has before his accurate investigations been supposed, and that its structure is that of a net-work, in the meshes of which the bioplasson fluid, or the not contractile, not living portion of the organism exists. He discovered that the granules, which had been observed before, are not foreign or accidental occurrences, but that they are part and parcel of the living matter; that, in fact, they are the thickened points of intersection of the threads of bioplasson constituting the living net-work. Extending his investigations he found that what was true of the structure of bioplasson in the amœba, where a single unit-mass of living matter constitutes the entire individual, is true of the structure of bioplasson of all, even the highest, living organisms. The idea connected with the word *cell*, when this term was first applied to the organic form element, had, with the advance of microscopical and histological knowledge, gradually undergone such changes that the name had become a complete misnomer. Although 'cells' were still spoken of, it was understood that their essential constituent was living matter individualized into small, distinct masses. The existence in these of a nucleus, a nucleolus, even a nucleolinus and granules, was known; even thorns and processes had been observed occasionally. But all this knowledge of the structure of these elementary masses was fragmentary, until Heitzmann announced that the nucleus, nucleolus, granules and threads are really the living contractile matter; that it is arranged in a net-work containing in its meshes the non-contractile matter which is transformed into the various kinds of matrix characterizing different tissues; and that the tissue unit-masses of bioplasson throughout the whole body are interconnected with fine threads of the same living matter."

It is greatly to be regretted that the author does not confine himself to observations and legitimate deductions, but allows himself the wildest generalizations and speculations. What in the name of common sense are we to say to one who tells us that the human body is constructed on the plan of an amœba? And when we hear that it is by "will" that living matter may overcome the force of gravity our own gravity would be overcome were it not that the melancholy aspect of such pseudo science affects us more strongly than the ludicrous one.

Dr. Heitzmann, as is well known, has studied cells very zealously in hopes of determining to what extent their appearances may be taken as indices of the well being of the individual. That such a relation should exist is plausible, indeed probable, and Dr. Heitzmann is entitled to much credit for his assiduous labors, but we cannot but fear that, as is very natural, he should have been led away by his enthusiasm to believe that more has been accomplished than lookers on will admit. The following little anecdote speaks for itself: —

"Life insurance should be based upon microscopical examination, as well as on percussion and auscultation. Marriages should be allowed, in doubtful cases, only upon the permit of a reliable microscopist. Last season a young physician asked me whether I believed in the marriage among kindred. He fell in love with his cousin and so did his cousin with him. I examined his blood, and told him that he was a 'nervous' man, passing sleepless nights, and had a moderately good constitution. The condition being suspected in the kindred lady, marriage was not desirable for fear that the offspring might degenerate. So great was his faith in my assertions that he gave up the idea of marrying his cousin, offering her the last chance, namely, the examination of her blood. The beautiful girl came to my laboratory, and, very much to my surprise, I found upon examination of her blood a first-class constitution. The next day I told the gentleman, 'You had better marry her.'"

The illustrations, as might be expected from the well known skill of the author are, with few exceptions, admirable. That part of the text which is devoted to recording microscopical structure is of varying merit. Some descriptions are very good, others are wanting in clearness.

There is much to praise in the book, which certainly should be absent from the collection of no one who would keep himself acquainted with the progress of histology and watch the influence of leading minds on its development, but we must add with regret that we cannot recommend it as a safe or satisfactory guide to the student. T. D.

University College Course of Practical Exercises in Physiology. By I. BURDON SANDERSON, Professor of Physiology in University College, London. Philadelphia: Blakiston & Co. 8vo. Pages 75. 1882.

This little book is one of a class with which the last few years have made us familiar, it being a collection of exact directions for a series of carefully chosen elementary laboratory experiments. The directions are well given, brief, definite, and sufficient, and helped by a few useful though simple diagrams. The experiments are admirably arranged, and exhibit considerable ingenuity in attaining simple methods, a merit which the preface attributes largely to Dr. Augustus Waller. The largest fraction of the book is devoted to muscles and nerves, most of the remainder to chemical experiments. A few pages are devoted to demonstrations to be made by teachers. It seems improbable that the book could be used in an American school, where the courses are differently arranged. The very high price, $1.12, for a small book, we think will suffice to prevent its general use, despite its value and accuracy.

Medical and Surgical Journal.

THURSDAY, JANUARY 11, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

GOVERNOR BUTLER'S MESSAGE TO THE MASSACHUSETTS LEGISLATURE.

So much was expected by the curious from the inaugural message of Massachusetts' governor, it is not astonishing that, notwithstanding its great length, the rare and strange in it should have fallen below the anticipations of many. It was generally supposed that he would bear with a heavy hand upon the ungainly Board of Health, Lunacy, and Charity, whose unwieldy proportions and incompatible composition we have so often had occasion to call attention to. And, indeed, Governor Butler has made it plain that he is sensible of the absurdities involved in the present form of organization of that Board, and alive to some of the particulars in which important interests of the State suffer in consequence.

In discussing the management of the insane of the State the following passage, characteristic of the speaker, and containing some true though not new comments upon the conjoint polysyllabic Board, occurs: —

"The general supervision of these institutions is, by the Act of 1879, put under the Board of Health, Lunacy, and Charity, who manage them, so far as they are managed at all, through a commission of lunacy, and this is in addition to the other duties of this Board, to take care of the health of the paupers and a large proportion of the criminals of the State, and also their duties imposed upon them by statute, of ascertaining the quality of everything that everybody in the Commonwealth eats and drinks, and all the drugs and medicines we consume, and the quality of the cosmetics that the ladies are supposed to use. It will not be wonderful if we find such things have to be neglected by so versatile and overworked a board, especially as they all work without pay.

"Members of the Board interested in and capable of taking charge of the sanitary condition of the State find their duties in taking care of paupers distasteful; while those with an aptness for paupers have no sufficient knowledge of the laws of mental alienation to have superintendence of lunacy; and those having that scientific knowledge which would fit them for the latter work have no taste for looking after the sewerage or paupers, prisoners or cosmetics of the State. This incongruity has led to the resignation of nearly a majority of that Board, losing to the State the services of some of the best-fitted men, for portions of the work, upon it."

These remarks precede a sensible suggestion that no more money be spent in architectural follies, but that simpler provision be made for the care of the increasing number of the insane.

True as are the remarks in the above paragraph, they contain nothing of a sensational character, — unless we exclude the ladies' cosmetics, — and nothing which has not been stated quite as forcibly many times before. It is certainly very possible that, had the message aimed simply at creating a sensation at the expense of the Board, even more effective subjects in connection with the administration of some of its departments than the unaudited sale for dissection of almshouse babies might have been ventilated. If the knowledge of such material existed it may be reserved for treatment in one of the promised special messages, or it may be thought it can be made more useful in some other fashion. But we confess that all this part of the message seems somewhat tame and trivial compared with all that rumor promised.

Much as we have deplored the abolition of the old Board of Health, and poorly as we think those who were responsible for establishing the present mixed Board have deserved of the Commonwealth, we yet do not see any reasonable hope of a better order of things being established under the present executive. It is probable that several vacancies will occur upon the Board of Health, Lunacy, and Charity during the coming year; by filling these with able, earnest, and experienced men — if such will consent to serve on the mixed Board — Governor Butler can do something to mitigate some of the shortcomings which afflict him. We doubt if more will be in his power to do directly, however excellent his intentions may ultimately prove to be.

It is little to the credit of Massachusetts that she should allow such departments as those of health, of lunacy, and of charity to be brought within the domain of active politics; their efficiency has been impaired, and it would indeed be poetical justice if the individual whose dreaded election to the chief magistracy was made the ostensible excuse for their former consolidation should, however indirectly, be instrumental in restoring them to a more suitable independence.

The harm done to these departments is not confined, however, merely to the form of organization. The best men are not often willing to devote their energies and give their labor to the advancement of any work which is liable to be upset at any time according to the supposed exigencies of the political situation.

We have treated this subject seriously, as it is to us a serious one, but do not wish to be supposed incapable of appreciating the Governor's peculiar humor, or to be forgetful of the existence of a "gallery."

ROUTINE PRACTICE.

IF there is one tendency in medicine more mischievous than any other it is the tendency towards routine. Conversely, it may be said with almost equal truth that if there is one occupation in which routine methods are unfortunate it is the practice of medicine. Yet our profession is not the only one where this failing exists in marked degree. All artizans show it. Your carpenter falls into certain ruts in his way of doing things, and if there is something a little out of his ordinary line of experience, which you wish done, the chances are that he will be quite at a loss. Your plumber, mason, or painter does his

work in a perfunctory sort of fashion, and if you have certain changes which you desire to introduce in the method of its execution, or a new object which you hope to accomplish, he is likely to respond helplessly that he never learned to do that. Excepting for the manual facility, you find yourself more competent to devise and execute anything which is a little out of the beaten track of any journeyman laborer than that workman himself. "Remember," says Herbert Spencer, "how generally improvements in manufactures come from outsiders, and you are at once shown with what mere unintelligent routine manufactures are commonly carried on. Examine into the management of mercantile concerns and you perceive that those engaged in them mostly do nothing more than move in ruts that have gradually been made for them by the process of trial and error during a long succession of generations. Indeed, it almost seems as though most men made it their aim to get through life with the least possible expenditure of thought."[1]

If this tendency is vicions in those occupations where for the most part the work consists in carrying out the plans of another brain, what shall we say of it in that profession where the work is never alike in any two cases? No two patients have the same constitutional or mental proclivities. No two instances of typhoid fever, or of any other disease, are precisely alike. The intelligent and efficient care of any case of illness demands a consideration of all the circumstances which are peculiar to itself and of the traits of body and of mind which are peculiar to the patient. No "rule of thumb," no recourse to a formula-book, will avail for the proper treatment even of the typical diseases. Above all, what is the mere *routinist* to do in the presence of those protean groups of symptoms which characterize the complicated associations and conditions of our modern social life?

A prolific writer on medical topics, in a pamphlet on the longevity of brain-workers, speaking particularly of physicians, says that the nature of the work is favorable to health in respect that the hardest portion of it, which consists in the *learning*, comes during that period, from twenty to forty, when man is best capable of severe labor, and that after that age there is only practice, which is comparatively easy. And he compares this with the case of the mere muscle-worker, whose tasks undergo no alleviation with his advancing years. We cannot but regard this as an unfortunate comparison. We do not believe that the actual mental labor of the intelligent and conscientious physician diminishes after his middle age. With an increasing practice there is an increasing number, if not proportion, of cases requiring careful, painstaking study. An easy-going application of knowledge gained in youth is not the true conception of the practice of medicine at any period of life. It has an unpleasant suggestion of routine methods.

While hospital service is, when rightly used, of inestimable value as affording the best opportunity for studying disease and observing and recording its phenomena in a complete and orderly manner, as well as giving exceptional chances for controlling conditions, yet this very work, capable of yielding so much advantage, is often debased to the merest routine. With a large number of patients, and especially with much outside business, men are tempted to slight their work, and to treat the cases merely with reference to a diagnosis (itself more or less imperfectly formed) rather than with reference to the individual needs. This is especially true of dispensary practice. Indeed, we have heard a physician of eminence counsel a young man not to undertake dispensary work, undoubtedly from the consideration that with the large numbers of cases, many of them uninteresting personally and professionally, which the young man would be called to treat, the tendency would be very strong toward superficial, unconsidered, and routine practice. Of course it is possible, by being on one's guard, to avoid this snare, and so to take the good of an increased number of cases, remembering that each presents its point of peculiarity and interest if one only has time to search it out. But to this end one can hardly be too much impressed with the shiftless, unscientific, and fatal results of routine practice.

THE COMPULSORY DISINFECTION OF TYPHOID EXCRETA.

IN response to the discussion in the Clinical Section of the Suffolk District Medical Society, to which a paper by Dr. Morton Prince on Typhoid Epidemics and the Necessity for Compulsory Disinfection gave rise, that Section passed the following resolutions, which were subsequently referred to and acted on by the District Society: —

Resolved, First, That in the opinion of this Society the history of the past has shown that one great element in the causation and spread of typhoid fever lies in the diffusion of the poison by the intestinal discharges of persons sick with the fever, and this Society recommends that their discharges be thoroughly disinfected in every case before being disposed of in the privies and sewers.

Resolved, Second, That we as members of this Society pledge to the State Board of Health, Lunacy, and Charity, and to the Board of Health of this city, our moral support and hearty co-operation in carrying out whatever measures they may deem necessary for the prevention of typhoid fever and other contagious diseases.

Resolved, That in the opinion of this Society the number of towns availing themselves of the present statute relating to the appointment of boards of health and health officers throughout the Commonwealth is much less than the public welfare demands, being much less than half the whole number, this Society recommends to the Suffolk District Medical Society to memorialize the State Legislature for the enactment of such laws as are necessary for the prevention of disease and to raise sanitary legislation to the present standard of sanitary science.

Resolved, That the secretary of this Society is hereby directed to present these resolutions to the Suffolk District Medical Society at its next meeting, with a request that a committee be appointed to take them into consideration.

The Boston Board of Health has already issued a circular for the purpose of inducing greater care in preventing the spread of typhoid fever. In it a simple statement is given of the most usual sources and ways of diffusion of the typhoid poison, accompanied by plain directions for the management of the sick-room, and for the disinfection of the discharges, the importance of which is duly dwelt upon. For this

latter purpose a five per cent. solution of chloride of zinc is recommended as being effectual, and without odor or stain.

As far as compulsory disinfection goes this is about as much as can be done by boards of health. The good work of propagandizing the gospel of salvation from typhoid must be carried on by the individual medical missionary, and inculcated line upon line, precept upon precept. Practically the disinfection will be voluntary rather than compulsory. A good deal may thus be done to diminish typhoid, but we need not indulge the illusion that we are in any way in a position to banish it. It is, we fear, a form of disease which we are likely to have always with us. With the most willing and intelligent coöperation on the part of health boards, of physicians, and of the public, the mild, unrecognized, ambulatory cases alone would insure a survival of the germ or ferment, and any of the carefully recorded epidemics, such as that at Lanten or at Caterham, show the extreme tenacity of life and diffusibility of the poison as contained in the excreta from the bowels.

MEDICAL NOTES.

— We have received the prospectus for the current year of the *Annals of Anatomy and Surgery*. This journal devotes itself particularly to "those lines of anatomical research which have a bearing upon practical surgery," and in order that it may be under no restraint as the organ of any one society it has ceased to represent especially, as heretofore, the Anatomical and Surgical Society of Brooklyn, and the editors will henceforth conduct it upon their individual responsibility. We welcome the *Annals* as a worthy exponent of American surgery.

— The U. S. Marine Hospital Service has issued a circular to the masters of steamboats plying upon western waters, offering the services of that department for the free vaccination of all the crews of such vessels, and giving suggestions for the burning of infected bedding instead of its being thrown into the water. This circular is called forth by the fact that one hundred and forty-three cases of small-pox were taken from ninety-five vessels during last season.

— The appropriation for the Army Medical Museum and Library, in regard to which we expressed our opinion, was, on motion of Mr. Butterworth, restored to the usual amount, namely, $10,000.

— Dr. Eliza M. Mosher, Superintendent of the Woman's Prison at Sherborn has resigned on account of ill health.

NEW YORK.

— At a meeting of the Board of Estimate and Apportionment, held December 18th, Dr. Chandler asked for $10,000 to defray the expenses of inspecting defective plumbing.

— The last report of the Department of Public Works shows that during July, August, and September the public baths were used by 1,460,800 males and 555,833 females.

— Dr. J. Lewis Smith read a paper on the Sequelæ, Complications, and Treatment of Scarlet Fever before the Section of Theory and Practice of the Academy of Medicine on Tuesday evening, December 19th.

— The death of James Hurst, State Taxidermist, which occurred at Albany, December 18th, in the seventieth year of his age, is said to have been caused by the absorption of arsenic used in his occupation.

— Dr. M. A. Pallen having resigned the chair of Gynæcology in the New York Post-Graduate School, Dr. B. F. Dawson has been appointed to the position.

— For some time past the committee on the course of studies of the Board of Education has been investigating the question whether the pupils in the public schools are not overtasked, and at a meeting of the Board held December 20th made their final report, which was, in part, as follows; "The general purport of the testimony given would lead to the opinion that the course of study, as a whole, is not excessive in its requirements; that it does not impose labor that cannot be accomplished without detriment to the health, strength, and comfort of either teacher or pupil in our public schools. In making this general statement it is recognized and admitted that individual instances have occurred in which objections might be made to the requirements of the course as excessive, and to its unfavorable influence upon the pupils. But when we reflect that at least 125,000 children are in daily attendance, and that the course of study was prepared with the view of meeting the needs and ability of the many and not of the few, these individual instances are not numerous and strong enough to serve as an indictment against the course, or even as a reasonable charge against its general merits, usefulness, and applicability."

— In his message of January 1st the new mayor, Mr. Edson, congratulates the city authorities, and especially the Board of Health, on the comparative freedom of New York from contagious diseases during the past year, and states that he is informed on the best authority that at the present time there is not known to exist here a single case either of small-pox or of typhus fever. The constant surveillance which is exercised over the ventilation, the drainage, the plumbing, and other sanitary conditions of old buildings, he says, is illustrated by the fact that 20,583 orders for the abatement of nuisances were issued during the year ending November 30, 1882. In speaking of the public schools he says that it is shown by recent careful estimates that the school-room space in the whole city is equal to the accommodation of 152,030 pupils, allowing to each pupil the modicum of sitting-room and air-space deemed proper by authorities in sanitary science, while the average attendance is only 129,794; showing an excess of school-room space over present necessities equal to the accommodation of more than 22,000 pupils. As a fact, however, the schools in many portions of the city are very much overcrowded, and the mayor suggests, therefore, that some measures should be taken to provide requisite school accommodations in such parts as are in need of them, and, perhaps, through some change of policy on the

part of the Board of Education, to arrive as rapidly as possible at a more equitable distribution of the school-room space.

— The appropriations for the various city departments for the coming year amount to over a million dollars more than those for 1882. Of this increased sum the Department of Charities and Correction gets $60,000 for a new insane asylum and $25,000 for the purchase of a farm for insane patients, and the Board of Health $50,000 for the erection of a hospital for children suffering from contagious diseases, which will be located at the foot of East Sixteenth Street.

— Governor Cleveland, in his inaugural message to the legislature, uses some very plain language in regard to the emoluments of the health officer of the port of New York. After stating that the amount paid from the State treasury for the maintenance of the quarantine establishment for the last fiscal year, including the salaries of three quarantine commissioners, was $35,000, he goes on to say that from a report of a special committee appointed by the Senate in 1881, it appears that while the fees and perquisites of the health officer were very difficult of exact ascertainment, the committee came to the conclusion that the net income of that officer did not average less than $40,000 per annum, and might, in favorable years, reach a sum upwards of $60,000. "No one," he continues, "can read this report without being convinced that this estimate is a very moderate one, and represents a sum of money derived from the commerce of our principal port, in startling disproportion to services rendered, and greater than any man ought to receive for official service. If the fees and charges are so high that the commerce of the port is injuriously affected by their collection, they should be reduced. If they are to be continued, all but a reasonable sum for the salary of the health officer should be applied, if legally possible, to the support of the quarantine establishment; and if this cannot be done, they should be so limited as to yield to the officer a fair salary only, thus relieving our commerce to that extent."

The information in regard to the charitable institutions of the State in the Governor's message is furnished by the State Board of Charities. During the year the Board has returned to various countries of Europe forty-eight lunatic, idiotic, crippled, blind, and otherwise disabled alien paupers, who have been shipped to New York by the authorities of foreign cities, or by relatives or guardians, in order to shift the burden of their support to American public charities. The number of insane in the various institutions on the 30th day of September, 1882, was 10,443. Of the insane in the State institutions, 2022, entirely of the chronic class, were confined in the Willard and Binghampton asylums. The number of insane persons in the several institutions throughout the State is 384 in excess of those reported at the close of the previous year. In view of the constant increase of insanity Governor Cleveland says: "The problem of the custody, care, and treatment of this pitiable class is crowded more and more upon the attention of all thinking citizens, and those who make their laws. I am satisfied that existing statutes on this subject need amendment. . . . If, as seems to be generally conceded, insanity is a disease needing special and peculiar treatment, it must be that the chance of improvement in those affected by this malady would be greatly increased if they could have the care afforded by an institution especially established for its treatment."

PHILADELPHIA.

— The annual meeting for the election of officers of the County Medical Society was held January 3d. The following were elected for the ensuing year: President, Dr. William H. Welch; Vice-Presidents, Drs. Addinell Hewson and W. R. D. Blackwood; Recording and Reporting Secretary, Henry Leffmann; Corresponding Secretary, H. Augustus Wilson; Assistant Secretary, Joseph S. Neff; Treasurer, L. K. Baldwin; Librarian, C. M. Seltzer.

Miscellany.

A TOAST FROM DR. FORDYCE BARKER TO DRS. HOLMES AND BIGELOW.

We take pleasure in being permitted to print the following pleasant and characteristic note from Dr. Fordyce Barker, of New York, to Dr. C. B. Porter, of this city, containing a toast to Drs. Holmes and Bigelow on the occasion of the late reception given by Dr. Porter in their honor.

Dr. Barker's kindly social nature is constantly betraying itself in these happy touches: —

December 25, 1882.

Dear Doctor Porter, — When I wrote to you last week a conditional acceptance of the invitation to be present at the reception to be given by you to Dr. Oliver Wendell Holmes and Dr. Henry J. Bigelow, I indulged the delusive hope that I might have during the holidays a little "rest from my labors," and that by a short visit to Boston, I should be physically benefited and mentally and morally improved. But a new invasion of calls has quite convinced me that my hopes were illusive.

I particularly regret that it is not in my power to be present, because, on a review of my past life, I find that the two acts of mine which have received the warmest and most universal approval of the profession in this city were those by which I secured to the profession the opportunity of seeing and hearing those two gentlemen whom your guests meet to honor.

Several years since, Dr. Holmes came to this city, in response to an urgent call from the Faculty of Bellevue Hospital Medical College, and gave the valedictory address at the College Commencement, on which occasion the Academy of *Music* was crowded with an immense audience of our best people, and many hundreds were disappointed because they could not find even "standing room."

Last year, by persistent and pertinacious persuasion, I succeeded in inducing Dr. Bigelow to come here and give a lecture before the New York Academy of Medicine, which brought to the hall of the Academy not only all of our leading surgeons, but a mass of the general profession, who wished to hear one whose good work was so well known, and who had won such lau-

rels at the International Medical Congress in London.

My heart will be with you on the evening of the 28th of December, and if it be permitted to offer any toast on that occasion, allow me to propose the following: —

Dr. Oliver Wendell Holmes and Dr. Henry J. Bigelow. May the effects of the lead-poisoning with which the former was saturated in early life, be long-continued, to add to the happiness and wisdom of the world; and may the latter long labor to crush and wash away the fossils of error in medicine, and especially in surgery.

I beg that you will give to both of these gentlemen the assurance of my distinguished consideration and my warm regards.

I remain, very sincerely yours,

FORDYCE BARKER.

APPOINTMENT OF DR. OLIVER WENDELL HOLMES EMERITUS PROFESSOR OF ANATOMY IN HARVARD UNIVERSITY.

THE Committee of the Board of Overseers of Harvard University, to whom was referred the vote of the President and Fellows appointing Oliver Wendell Holmes, M. D., LL.D., Emeritus Professor of Anatomy, report that: —

For more than thirty-five years Dr. Holmes has filled the chair of Parkman Professor of Anatomy. Taking great interest in his classes, he has met them with conscientious punctuality and never-failing enthusiasm. By the ingenuity of his demonstrations, the vividness of his descriptions, the brilliancy of his imagination, and the ever ready resources of his varied erudition, he has given to the dry details of a difficult study a rare attraction; each lecture, prepared with exact fidelity, being delivered with all the freshness of a first occasion.

Earnest for the improvement of medical education, cautious as to important changes, he adopted and scrupulously carried out those which he was convinced would do most for the attainment of his great object, the best instruction of his pupils.

His services to the community have been valuable and constant. In societies, before boards of health and committees, he has exerted his eloquence in behalf of thorough medical education, measures of sanitary reform, charities, and public improvements. He has hastened the advance of rational medicine. He urged the practice of what is now technically called "surgical cleanliness" before Listerism was heard of. His writings add dignity to the profession of medicine, increase respect for the honorable and educated physician, and discourage the charlatan.

The retirement of a professor whose reputation has contributed so much to that of the university calls for an expression of profound regret, and for the fullest academic recognition of his long and zealous devotion to its interests.

The committee recommend that this Board concur in the vote of the President and Fellows.

Signed { R. M. HODGES. HENRY LEE. MORRILL WYMAN.

January 10, 1883.

REGULATION OF PLUMBING IN THE CITY OF BOSTON.

THERE is now under consideration by the city government of Boston an ordinance of especial significance, as showing the increased importance which is coming to be attached to sanitary science. It is in fourteen sections, and provides first for the registration of every person who carries on the business of plumbing; and that in all cases of new work or alteration of old work notice of what is to be done shall be filed with the Inspector of Buildings. The succeeding sections prescribe in detail rules for material, grade, and location of pipes, for traps, and fresh air inlets to all house-drains, and to each separate fixture, for extension of soil-pipes above the roof, and in general all the most recent precautions and safeguards which sanitary engineers are agreed upon. Finally, it directs that in every case the plumber shall notify the inspector when the work is sufficiently advanced for inspection, and before any of the pipes are concealed from view. That all new work shall be examined by the inspector with the peppermint test, and in case any imperfection is disclosed that the water shall be turned off from the building and not let on till the plumbing is pronounced satisfactory by the Inspector of Buildings.

For any violation of the provisions of the ordinance a fine of not less than twenty nor more than fifty dollars is imposed.

WRITER'S CRAMP.

A WRITER in the *London Medical Record* describes an invention of Professor von Nussbaum for the treatment of writer's cramp. The device was tested and found successful in a large number of cases obtained for the experiment by means of an advertisement of a "gratis cure." The apparatus depends upon the theory that whatever may be the cause of the affection, the normal antagonism of the muscles is pathologically altered, a spastic contraction of the flexors and adductors being always associated with weakness of the extensors and abductors. If, then, one could construct such a pen-holder as could be manipulated by the extensors and abductors instead of by the flexors and adductors, the cramp could not possibly occur, and thus the act of writing would prove the best means of curing a writer's cramp.

Acting upon this idea, Professor von Nussbaum constructed a kind of "bracelet" of gutta-percha, of an irregularly oval shape, and about three inches and a half in diameter, just wide enough to admit all the fingers. Thrusting the thumb and first three fingers into this bracelet, he found that strong extension of the inclosed fingers and abduction of the thumb were necessary to keep it fixed in its place. To the upper surface of the bracelet a pen-holder was attached by a screw, and adjusted so that the point of the pen should lie in a convenient position for writing when the hand was laid flat upon the table.

The more powerfully the movements of extension and abduction are employed, the more firmly will the bracelet be held, and, as a consequence, the better will be the writing. The form of the bracelet admits of variation, the object being to give employment as fully as possible to those muscles which, in the writer's cramp, remain weak and inactive, and thus to restore a normal antagonism between the two sets of muscles.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 30, 1882.

Deaths reported 2579 (no reports from St. Louis and New Orleans): under five years of age 908: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 549, lung diseases 386, consumption 357, diphtheria and croup 196, small-pox 87, typhoid fever 67, scarlet fever 62, diarrhœal diseases 42, whooping-cough 24, cerebro-spinal meningitis 18, malarial fevers 18, measles 15, erysipelas 15, puerperal fever 15. From *scarlet fever*, Brooklyn 14, Buffalo 11, Chicago nine, Philadelphia six, New York, Baltimore, and Cincinnati five each. From *diarrhœal diseases*, New York 14, Providence eight, Chicago four, Brooklyn three, District of Columbia, Buffalo, and Milwaukee two each, Boston, Baltimore, Cincinnati, New Haven, Fall River, Taunton, and Milford one each. From *whooping-cough*, New York eight, Pittsburg five, Cincinnati three, Philadelphia two, Brooklyn, Boston, Baltimore, District of Columbia, Fall River and Springfield one each. From *cerebro-spinal meningitis*, New York six, Boston, Worcester, and Lawrence two each, Philadelphia, Chicago, Fall River, Lynn, Springfield, and Taunton one each. From *malarial fevers*, New York nine, Brooklyn five, District of Columbia three, Baltimore one. From *measles*, New York seven, Philadelphia, Cincinnati, and Buffalo two each, Boston and Providence one each. From *erysipelas*, Boston four, Chicago three, New York and Cincinnati two each, Pittsburg, Milwaukee, Providence, and Peabody one each. From *puerperal fever*, Chicago four, Boston three, Philadelphia two, New York, Baltimore, Pittsburg, Milwaukee, New Haven, and Newburyport one each.

Three hundred and one cases of small-pox were reported in Baltimore, Cincinnati seven, Brooklyn two; diphtheria 66, scarlet fever 16, and typhoid fever eight, in Boston; scarlet fever 12, diphtheria three, in Milwaukee.

In 33 cities and towns of Massachusetts, with a population of 899,213 (population of the State 1,783,086), the total death-rate for the week was 23.36 against 20.75 and 20.78, for the previous two weeks.

For the week ending December 9th, in 170 German cities and towns, with an estimated population of 8,443,620, the death-rate was 23.7. Deaths reported 3848: under five years of age 1694; consumption 327, lung diseases 249, diphtheria and croup 248, diarrhœal diseases 110, scarlet fever 84, measles and rötheln 58, typhoid fever 58, whooping-cough 47. The death-rates ranged from 14.1 in Wiesbaden to 35.3 in Braunschweig; Königsberg 29.1; Breslau 24; Munich 26.9; Dresden 29.6; Berlin 20.9; Leipzig 18.7; Hamburg 22.6; Cologne 24.4; Frankfort a. M. 17.8; Strasburg 21.4.

In the 28 English towns, with an estimated population of 8,469,571, for the week ending December 16th, the death-rate was 26.9. Deaths reported 4370: acute diseases of the respiratory organs (London) 637, measles 134, scarlet fever 95, whooping-cough 85, fever 79, diarrhœa 46, diphtheria 23, small-pox (Newcastle three, Birmingham, Oldham, and Sheffield one each) six. The death-rates ranged from 18.9 in Bristol to 37.7 in Halifax; Birkenhead 20.5; Birmingham 23.8; Sheffield 24.1; Newcastle-on-Tyne 26.2; Sunderland 27.6; Nottingham 29.1; Liverpool 34; Preston 35.3. In Edinburgh 25.6; Glasgow 35.5; Dublin 33.6.

For the week ending December 16th, in the Swiss towns, population 494,390, there were 40 deaths from consumption, acute diseases of the respiratory organs, 23, diarrhœal diseases 12, diphtheria and croup six, typhoid fever five, scarlet fever three, puerperal fever three, whooping-cough one. The death-rates were, at Geneva 15.4; Zurich 17.3; Basle 19.6; Berne 23.

The meteorological record for the week ending December 23d in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

A PRIZE ON THE PREVENTION OF BLINDNESS.

THE Fifth International Congress of Hygiene, which will meet at The Hague, Holland, in 1884, will award the prize of two thousand francs offered by the London Society for the Prevention of Blindness to the author of the best essay written in English, French, German, or Italian on The Causes of Blindness and the Practical Means for Preventing It. Besides this prize the International Society for the Improvement of the Condition of the Blind reserves to itself the right to award a second prize of one thousand francs or two prizes of five hundred francs each and a silver gilt medal with a diploma, should it see fit, to such of the essays as should, in the opinion of the international jury for the principal prize, be deserving of it; the last-mentioned prizes will be distributed at the centenary festival of the first blind institution founded by Hauy, which will take place in Paris in 1884.

The Fourth International Congress of Hygiene, which met at Geneva in September, 1882, adopted for this competition the following programme, as prepared by the London Society for the Prevention of Blindness: —

I. The Study of the Causes of Blindness: (*a.*) Hereditary causes. Diseases of parents, consanguineous intermarriages. (*b.*) Infantile eye diseases. Various inflammations of the eyes. (*c.*) School period and time of apprenticeship, progressive short-sightedness, etc. (*d.*) General diseases, diatheses, various fevers, chronic poisoning, etc. (*e.*) Trade influences, wounds, and accidents, etc., sympathetic ophthalmia. (*f.*) Social and climacteric influences, contagious ophthalmias, unhealthy habitations, defective lighting, etc. (*g.*) Neglect of treatment and bad treatment of eye affections.

II. The Study of Practical Preventive Means: (*a.*) Legislative means. (*b.*) Hygienic and professional means. (*c.*) Educational means. (*d.*) Medical and philanthropic means.

The International Jury, elected by the Geneva Congress, for the purpose of judging the essays, consists of: —

Dr. Snellen, professor of ophthalmology, Utrecht.

Dr. H. Cohn, professor of ophthalmology, Breslau; Dr. Berlin, professor of ophthalmology, Stuttgart.

Dr. Fieuzal, physician to the Hospice des Quinze-Vingts, Paris; Dr. Layet, professor of hygiene, Bordeaux; Dr. Coursserant, oculist, Paris.

Dr. Reymond, professor of ophthalmology, Turin.

Dr. Sormani, professor of hygiene, Pavia.

Mr. Streatfield, professor of ophthalmology, University College, London; Dr. Roth, honorary secretary and treasurer (*pro tem.*) of the Society for the Prevention of Blindness, London.

Dr. Dufour, of the Ophthalmic Hospital, Lausanne.

Dr. Haltenhoff, lecturer on ophthalmology, Geneva, and secretary to the jury.

Those essays to which prizes shall be awarded shall become the property of the Society for the Prevention of Blindness and of the International Society for the Amelioration of the Condition of the Blind, who will be at liberty to publish them in whole or in part in several languages, in order to make them useful in the way they consider best. Manuscripts for competition are to be sent to the secretary not later than March 31, 1884, every manuscript to be distinguished by a motto, which is also to be written on a sealed envelope containing the name, Christian name, titles, and address of the author. The envelopes will not be opened until after the award of the jury.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 29, 1882, TO JANUARY 5, 1883.

MCKEE, J. C., surgeon. To report on or before January 1, 1883, to the commanding officer, Fort Winfield Scott, Cal., for assignment to duty as post surgeon. Paragraph 1, S. O. 197, Department of California, December 28, 1882.

GORGAS, W. C., assistant surgeon. Relieved from the temporary duty to which assigned under paragraph 4, S. O. 137, Department of Texas, and will report to the commanding officer, Fort Brown, Texas. Paragraph 2, S. O. 140, Department of Texas, December 26, 1882.

HOPKINS, WILLIAM E., assistant surgeon. Granted leave of absence for two months, to commence January 1, 1883, with permission to apply for an extension of two months. Paragraph 1, S. O. 88, Military Division of the Atlantic, December 28, 1882.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FOR THE WEEK ENDING JANUARY 6, 1883.

HENRY B. TIBBS, assistant surgeon. Ordered to the U. S. S. Jamestown.

CORRECTION. — Nathaniel G. Kierle, M. D., is Lecturer on Pathology, College of Physicians and Surgeons, Baltimore, and not in the University of Maryland, as reported in the article on New Lenox Malaria Case in our issue of December 28.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at the Medical Library, No. 19 Boylston Place, on Monday, January 15, 1883, at eight o'clock P. M. Reader, Dr. G. K. Sabine. Subject, A Case of Caries of the Ribs, with Abscess of the Chest. Dr. W. J. Otis will read A Case of Exfoliation of the Mucous Membrane of the Bladder from Cystitis following Confinement.

C. M. JONES, *Secretary.*

SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION FOR OBSTETRICS AND GYNÆCOLOGY. — There will be a meeting of the Section at 19 Boylston Place, on Wednesday, January 17th, at eight P. M. Regular paper by Dr. W. A. Dunn. Subject, Results in Five Hundred Labor Cases.

J. B. SWIFT, *Secretary.*

OFFICERS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT FOR 1883. — At the annual meeting of the Boston Society for Medical Improvement, held January 8th, Charles D. Homans, M. D., was elected President, and Edward M. Buckingham, M. D., Secretary, for the ensuing year.

APPOINTMENT. — Dr. O. G. Cilley has been appointed by the Governor Surgeon-General of Massachusetts.

Lectures.

CLINICAL LECTURE.[1]

BY DAVID W. CHEEVER, M. D.,
Professor of Surgery, Harvard University.

I. CELLULAR ABSCESS.

GENTLEMEN, — The first case which I bring before you to-day is that of this little girl, who came here a week ago with a hard bunch upon her left wrist. This bunch has now softened. It gives rise to great apparent deformity and protrusion of the ulna, which appearance, however, is deceptive. The wrist-joint moves freely in all directions, without pain. There is a sac containing pus, which I proceed to incise. If the pus is due to caries, the disease at all events does not affect the joint, and it is doubtless merely an inflammation of the cellular tissue.

II. PUNCTURED WOUND OF HAND; LIGATURE OF THE BRACHIAL ARTERY.

This little boy, about six years of age, nearly three weeks ago drove a penknife into his hand, in the neighborhood of the first carpo-metacarpal articulation. The immediate hæmorrhage was slight. One week after the injury, however, profuse secondary hæmorrhage occurred. The physicians in attendance prolonged the original incision from the *tabatière* toward the seat of the radial artery in the wrist, and made an attempt to secure the bleeding vessel, but without success. A firm compress was then applied to the hand, and the boy was sent from his home, two hundred miles distant, to Boston, where he arrived exhausted and pale from the amount of blood that had been lost. On taking off the twist from the hand I found a foul suppurating cavity at the site of the incision; also a superficial slough on the ulnar side of the hand, due to pressure of the bandage. No blood appeared from the vessel, but there was reason, in view of the bad condition of the parts, to suppose that hæmorrhage would recur. I therefore ligatured the brachial artery. The operation was performed under the spray, and Lister dressings were applied. This was eleven days ago. While there has not been absolutely first intention, the wound has practically healed, as you see, the granulations having come up to the level of the skin. The ligature, which was of catgut, never came away, and there is reason to believe that it has been absorbed. There is no further danger, now, of secondary hæmorrhage, and the child can go to his home in a few days.

There are two points worthy of attention in this case. First, the safety of tying the brachial, so far as concerns danger of mortification of the hand, and its advantages as serving to secure the interosseous arteries. By applying the ligature to this vessel, we also avoid the neighborhood of the sloughing tissues about the wound. Secondly, the prompt establishment of the collateral circulation. On the eighth day after the operation I detected pulsation in the ulnar artery, and on the ninth it was observed in the radial. It is now perfectly restored in both. In this case the nails have retained their bright pink color throughout, and the hand has been warm.

III. ULCER OF THE UPPER LIP.

This man, as you will observe, has upon his upper lip an ulcer, with ragged, hard edges. It has been there for six or seven months. He has also had for the past three months venereal sores upon his privates, which have not healed yet. These sores, however, seem to be antedated by that upon the lip. The question in this case is whether the man has a primary specific sore upon the lip, or whether the ulcer is a degenerating epithelial growth. The patient himself ascribes the sore to irritation from a pipe, aggravated by neglect. I can detect no enlarged glands in the neck, and there appears to be no soreness on either side.

It is important to decide on the nature of this sore within a few weeks for the sake of the treatment. The man says he has taken no medicine. We will therefore put him at once upon a course of mercurials, and follow it up vigorously for three or four weeks, either alone or in connection with the iodide. If by that time the sore has not begun to heal, it should be excised.

IV. ACUTE SYNOVITIS OF THE WRIST.

This lad is in the employ of a tailor. He tells me that he is not called upon to do heavy lifting or other work which would be likely to strain his wrist. He had previously been in good health, when suddenly, six days ago, he was taken with pain in the wrist, without having had any injury. Stiffness, swelling, and deformity came on at once, preventing the use of the hand. The hand appears pushed over to the radial side. The swelling is confined to the ulnar side, and there is great tenderness through the ulnar articulation. He tells me that this is the only point affected, and that he never has had rheumatism. The localization of the trouble makes it look like acute synovitis, which, in the absence of any strain or injury, may be of rheumatic origin. As to the treatment, we will begin with the theory of rheumatism. The hand should be placed on a splint; we will give him colchicum internally, and locally lotions of laudanum and camphor, to be followed later by iodine. If the disease is rheumatism it will probably be relieved by this treatment. If synovitis it will assume an indolent type, and continue a long time.

V. COMPLETE CONGENITAL EXTROVERSION OF THE BLADDER.

While the next patient is being etherized I will say a few words about the case, and will then demonstrate the pathological condition, and afterwards perform the operation in your presence. It is a girl, six years of age. She presents a defect of the fœtal development. The anterior abdominal walls have never completely closed along the median line of the body. There is no umbilicus. The recti muscles separate at a point above where the umbilicus should be, and spread out at an angle, till they become attached to the pubes at quite a distance one from the other. The pelvic bones themselves are separated by a wide interval. The anterior wall of the bladder is absent, and the posterior surface of the mucous membrane is presented to view with the ureters discharging upon it. The interior of the bladder is thus exposed to the air. When the patient is at rest the exposed surface is comparatively flat, but when she coughs, vomits, or strains, it rises up and is pushed forward, in shape and size like a billiard ball; it then bleeds readily, and, as you can imagine, is much irritated by the clothing. There is no urethra, clitoris, or nymphæ. The labia majora lie to the sides by the separated pubic arch. There is a rudimentary

[1] Specially reported for the JOURNAL.

vagina, which, as has been noted in other similar cases, lies transversely. The probe enters the vagina an inch and a quarter, and sweeps on either side into a pouch, which is the analogue of the Douglas' cul-de-sac in the normal female. The finger introduced into the rectum discovers a small ovoid body, which is probably the rudimentary uterus. The rectum itself appears to be normal.

This is, then, a case of complete exstrophy of the bladder, a disease rare in itself, and especially uncommon in this sex. Of forty recorded cases only seven occurred in females. The inconveniences of the condition are obvious. The child is kept always wet by the trickling urine; excoriation of the skin follows. The tumor is exposed to a constant friction. The mouths of the ureters being constantly irritated, may become blocked by a phosphatic deposit, which is a source of danger. Yet the condition is not inconsistent with life. This child is likely to grow up. Instances have been recorded in which persons thus afflicted have reached the age of seventy or eighty years.

From separation of the recti, and general weakening of the abdominal walls, we find that this deformity often gives rise in males to double inguinal hernia. In this child the rings are elongated, narrow slits, against which the intestine can be felt on cough, but into which it does not enter. The child is, therefore, thus far free from hernia; moreover, her digestion and other functions are good, and she may be considered healthy.

Now, on uncovering the parts, you will see that at a point a little below where the umbilicus should be, there is a crescentic line, where the transversalis fascia ends. Below this the tissues are soft, consisting only of the skin and peritonæum over the intestine. Below this is the convex surface of the tumor, presenting a groove with two lateral lobes, and in shape looking not unlike the conventionalized "heart" depicted on playing cards. This is the trigone, and on the edge are the two ureters, which admit, as you see, a fine probe, and are constantly oozing with urine. You see the rudimentary labia, and the absence of the nymphæ. This transverse slit, looking like the meatus, is in reality the ostium vaginæ. Below, the perinæum and raphé are normal. The excoriations about the anus, looking like condylomata, are due simply to the irritation of the urine. The fullness which you see over the separated pubic bones is due chiefly to fat, and in the male often contains a double inguinal hernia. But here, as I have said, the ring is empty. My finger and thumb are on the spines of the pubes, which by measure are nearly three inches apart. Above the bladder the angle formed by the receding recti can be readily seen. The existence of the urachus is denied in these cases. The umbilical cord is attached about at the upper edge of the bladder, and here the umbilical vessels terminate. The deformity is due in these cases to a failure of the anterior layer of the allantois to close. The smallest degree of the same abnormality is seen in the condition known as epispadias. A few years ago there was a man who earned his living by going about the country and exhibiting his extroverted bladder before the various medical classes.

The treatment of this deformity may be mechanical or operative. In the former case a urinal is arranged with a metal cup communicating with a reservoir hanging along the thigh. This is hard to adjust and keep in place, and would be especially so in a child of this age. Operative measures may be divided into two classes, radical and plastic. The former attempts to direct the ureters into the rectum, thus making the lower pouch of the rectum into a bladder, which is to be controlled by the sphincter ani, and which will expel the urine as is necessary, either with or without the fæces. This has often been attempted, and several operations for this purpose have been described. All that I have seen, with one exception, have been disastrous. The patient has usually died either from cellulitis or peritonitis. In those that have survived the result has not been successful. The difficulty is that the peritonæum is displaced like all the other viscera, and one cannot tell how low it comes down. Normally it should go no lower than the line of the trigone. In two cases operated upon in London the peritonæum was perforated, and there was intra-peritoneal extravasation of urine. Another difficulty is that even if the operation is primarily successful the ureters may become blocked up by a phosphatic deposit. To perform this operation it is necessary to pass a fine probe into the ureter; the finger is introduced into the rectum. Then two needles are passed from the rectum, and the lower half inch of the ureter is held in the loop of thread. This is then tightened, and the ureter sloughs through into the rectum by an elongated opening.

T. Holmes' method is to slough the whole back wall of the vesical trigone into the rectum by means of a clamp, thus getting a large fistulous opening.

These operations are all open to the objection of being dangerous, and it is uncertain whether the rectum will tolerate the phosphatic deposits, and whether the sphincter will hold well.

The second class of operations are the plastic ones, where the object is to cover in the deformity by flaps of skin. We cannot hope to make a bladder which will hold water, but we cover it with skin in the expectation that the cicatrix will hold back the bladder, and will leave only an exposed point at the base where the ureters will discharge, and to which a urinal can be more accurately fitted.

T. Holmes' mode of operating is to take one square flap from the groin, and reflect it over the bladder, raw side uppermost. A second flap is cut obliquely from the other groin and labium or scrotum, and turned or slid over the first, raw surface downwards. A subsequent operation is required to unite the upper edges of these flaps to the wall of the abdomen, above the bladder.

John Wood's operation consists in raising an apron of skin from above the bladder, and turning it down so that the raw surface comes uppermost. Over this are brought two smaller lateral flaps with their raw surfaces downwards; these are joined along the median line, and all are stitched into the margins of the sound skin around the bladder.

Bigelow has grafted the skin directly upon the bladder by dissecting off the mucous membrane above the trigone, raising two flaps at the sides, and applying them with the raw surface downward to adhere directly to the bladder, thus occluding the upper three fourths of the viscus.

The operation which I shall do is that of Wood. The essential point is to have no tension, and thus to avoid sloughs. Cleanliness is also especially important. I take the flap from above, about to where the umbilicus should be. The side flaps I make from the groins

rather than from the sides of the abdomen, as Wood does, as by his method almost the whole belly is flayed. You will observe that the side flaps taken from the groin infringe upon the erectile tissue about the vulva, and thus give rise to considerable hæmorrhage.

[After this had ceased the flaps were brought into excellent apposition, and stitched with wire and catgut. The protrusion of the bladder was entirely closed in except a small opening below. The skin of the belly was drawn together with two button sutures, and the raw surface over the abdomen two thirds closed. The wound was dressed with lint and carbolized oil, one to forty parts.]

ORBITAL CELLULITIS AS A SEQUEL OF FACIAL ERYSIPELAS.[1]

BY HENRY W. WILLIAMS, A. M., M. D.,
Professor of Ophthalmology in Harvard University.

THE importance of an early recognition of secondary inflammation of the cellular tissue of the orbit occurring as a consequence of facial erysipelas; the peculiar conditions often existing in and about the eyelids at the time of its development, which render its diagnosis more difficult; and the grave results which may attend it, make this somewhat rare affection one of much interest to the general practitioner.

After more or less complete convalescence from an attack of facial erysipelas, which has generally been of some severity, and usually attended with the formation of abscesses of the eyelids, the scalp, or the deep-seated cellular tissues of the face, the patient begins to complain of a sensation of fullness and of dull pain, which is sometimes intermittent, in or around the orbit. This is followed by lividity, swelling, and immobility of the lids, and by limitation of movement and gradually increasing protrusion of the eyeball. The pain is increased if the globe is pressed upon, but is not excited by pressure along the orbital margin. The exophthalmos is oftenest in a direction directly forwards; but the eye may be laterally displaced, or the axis of the globe deviated in any direction, in which case the patient perhaps complains of double vision. This protrusion and fixedness of the globe is an important diagnostic sign. When it is large in amount the lids are often crowded apart to such an extent as to expose the cornea and render it liable to ulceration. These conditions are accompanied by more or less conjunctivitis, with increased mucous secretion, and generally by chemosis of the subconjunctival cellular tissue, which is usually most considerable at the lower part of the globe. Rigors are sometimes experienced. As will be seen from the appended report of cases, fluctuation can rarely be detected at the early and most important stage of the disease, because, even when suppuration has already begun, it is very deeply seated, and the interposition of the elastic eyeball and Tenon's capsule between the purulent nidus and the surgeon's finger prevents an accurate estimate of the condition of the underlying tissues. Moreover, the thickened or scarred state of the eyelids, which often have been themselves the seat of abscesses during the acute period of the erysipelas, increases the difficulties of manipulative exploration.

[1] Read before the Boston Society for Medical Improvement, January 8, 1883.

Resolution of the inflammatory changes in the tissues may exceptionally occur, with or without treatment, as will appear from one of the cases reported; but this is so far improbable that, having in view the possible and in fact the ordinary course of the disease, we are usually not justified in either an expectant treatment, or in reliance on cold or emollient local applications, or leeches, or in delaying surgical intervention in the hope that spontaneous evacuation of an abscess may bring relief. This last is the probable eventual result of non-interference; but in the mean time numerous dangers are incurred: vision may be lost, without other serious changes; the cornea may be destroyed by ulceration occasioned by exposure or by increased tension; the inflammation may extend to the interior of the eyeball, causing suppurative ophthalmitis or destructive changes in the retina, the choroid, or the uveal tract; the orbital suppuration may make such extensive ravages in the fatty and cellular tissues that after recovery the globe will sink back in its socket, or its movements become limited by rigidity or adhesions of its muscles; the accumulated pus may make its way through the thin bony walls into the nose or the antrum; or, last and most serious of all, there is great danger to life, either from infiltration of pus into the cranial cavity through the superior orbital foramen, or from extension of the inflammation, by contiguity, to the meninges of the brain; or from the formation of intra-cranial thrombus or pyæmic deposits through the medium of the ophthalmic veins. That these last dangers are not imaginary is shown by the report of a number of cases lately collected by Weber, of which four fifths resulted fatally.

The ophthalmoscopic appearances observed are not usually those of neuritis. In one of my own cases, where sudden loss of vision led to an immediate examination of the condition of the fundus of the eye and the optic nerve, the ophthalmoscope disclosed only a lessened calibre of the retinal vessels and a resulting somewhat anæmic aspect and appearance of infiltration of the retina, without other obvious changes of the optic disk or of the fundus oculi. Subsequently a still further diminution of size occurred in the retinal vessels, and the optic disk exhibited some semblance of atrophic change, though this was less marked than in ordinary atrophy resulting from neuritis. Similar appearances to those last described were found in the other eyes where vision was lost; but in these I had no opportunity to make an ophthalmoscopic exploration directly after the loss of sight. In some cases where vision was preserved, circumstances made ophthalmoscopic examination impossible until after relief of the acute symptoms by evacuation of the abscess. The so frequently resulting amaurosis is attributed by some authors to neuritis, or to compression of the optic nerve itself; but the fact of the very sudden blindness, with the absence of marked changes of the optic disc, seems rather to indicate compression of the retinal vessels by the inflamed and indurated tissue which surrounds them, during their course through the deeper parts of the orbit and before they perforate the optic nerve to pass towards the eyeball. Lessening of the acuteness of vision may occur without its complete abolition, and should be regarded as an urgent reason for prompt surgical action, so as, if possible, to prevent permanent blindness.

Post-erysipelatous inflammation of the orbit perhaps arises from extension of the morbid processes, by con-

tiguity, from the facial tissues, or may be due to metastasis. Taking into account the previous history, which affords important information, the disease may usually be readily distinguished from other affections of the orbit. Cellulitis resulting from periostitis or from caries of the orbital parietes is less acute in its development, and the seat of inflammation can often be distinctly localized. Tumors of the orbit, or the exophthalmos of Basedow's or Graves's disease, frequently cause much displacement or protrusion of the eyeball, but seldom give rise to acute inflammatory processes. Pulsating tumors have special features which generally afford means of easy diagnosis. Emphysema, hæmorrhagic infiltration, or other results of accident, can be explained from knowledge of the exciting cause. Inflammation of the lachrymal gland is of exceeding rarity, is indicated by local tenderness, and generally occasions lateral displacement rather than great protrusion of the eyeball. Similar symptoms to those we have described are met with in cases of inflammation of Tenon's capsule, but the pain at the outset is there more violent. Cellulitis of other origin than already mentioned is very rare, except sometimes in a milder form in children, which usually has a favorable termination.

One instance is reported where, in a case which had been long neglected, and both the eyeball and surrounding tissues were protruded far beyond the orbital cavity and had become livid, a distinguished practitioner who saw the patient in consultation, not being allowed to make an exploratory puncture, found it difficult to decide whether the condition arose from orbital abscess or a malignant growth. The mystery was soon after explained by the bursting of an abscess, with immediate relief of the symptoms.

Early puncture is the only suitable treatment. It is not only harmless, but, if done before the formation of pus has begun, it may prevent suppuration by relieving the engorgement of the parts. Should matter not be discovered at one point other deep punctures should be made. If no accumulation is then detected we thus at least relieve the congestion and lessen the tension and the pain, and perhaps obviate the danger of grave lesions of structure or function. Furthermore, by a partial division of Tenon's capsule we open an outlet for the more ready escape of pus should it be subsequently formed. If relief is not obtained and the indications continue, renewed exploration is to be made on the next or on subsequent days. In doing this operation Graefe's cataract knife, or a narrow bistoury, is to be passed either through the conjunctiva or through the skin of the lids, at such place, if any, as from the displacement of the globe or otherwise appears to be designated as the situation of an abscess. Most frequently, the lower border of the orbit, near the inner or the outer canthus, is the place of election for the puncture. From these points the knife should be passed backwards between the recti muscles. But if there seems reason for believing that the abscess may thus be more easily reached, any other part of the orbital border may be selected, as with a very narrow knife and proper caution there is no chance of harm being done. The back of the knife should be towards the eyeball, and its point should be kept near the orbital walls, so as to avoid any possible injury of the globe, while care must also be taken not to give it such a direction, or so much force, as to penetrate through the thin bony plate at the roof or the inner side of the orbit. When there is much external swelling the abscess is sometimes found at a depth of two inches or more, and even then perhaps only after three or four punctures have been made without result. Should pus be discovered the external opening is to be sufficiently enlarged to admit of its free discharge; and, to prevent closure or obstruction of this outlet from the deep-seated cavity, a very narrow tent cut from a bit of cambric or a fine drainage tube should be introduced, and renewed until the discharge lessens or ceases. No pressure is required to evacuate the pus, for the existing tension of the parts suffices to insure steady retraction and a constant expulsion of the fluid. Warm fomentations are now often useful as well as grateful to the patient. Speedy recovery ensues, except where too long delay has induced periostitis and caries. Until within about two years I had never seen a case of orbital cellulitis consequent on erysipelas, but the fact that I have met with four cases of this character within seven months of the present year proves the importance of a recognition of these secondary conditions by those in whose hands nearly all patients thus attacked must necessarily remain for treatment. For purposes of comparison brief abstracts of cases, varying considerably in their phenomena and results, are appended.

CASE I. In the spring of 1880 I was asked to attend in consultation a gentleman about sixty years of age suffering from a somewhat severe attack of erysipelas, affecting the neck, scalp, forehead, eyelids, and face. Two abscesses of some size formed in the upper and one in the lower lid of the left eye, and one in the deep cellular tissue of the face near the left ala nasi. These having been freely opened, the infiltration of the lids and the conjunctival chemosis rapidly lessened, and all appeared to be going on well. Vision of the left eye was daily tested, and was apparently normal. But after two weeks of such steady improvement that the lids could be opened, and the whole aspect of the patient promised a speedy recovery, a rather sudden increase of chemosis was observed beneath the conjunctiva of the globe, towards both the canthi, together with a diminished power of rotation and a slight protrusion of the eye. The patient complained of a sensation of fullness without much pain at the temporal side of the orbit. Suddenly nearly all perception of light was lost in this eye. Examination with the ophthalmoscope showed a faint yellowish-gray aspect of the whole fundus, as if from a slight infiltration, without turgescence or other change of the optic disk, and a little diminution of calibre of the retinal vessels.

Although no fluctuation was discoverable, and the indications were indistinctly marked, it was believed that an abscess must be in process of formation at the bottom of the orbit, and exploratory puncture was advised. This being assented to ether was administered, and two very deep punctures were made with Graefe's narrow knife in the region most complained of by the patient, and where the position of the displaced globe seemed to indicate that pus might be found. Only blood escaped, and further operative search was deemed undesirable. On the following day, the symptoms persisting, a second attempt to find a purulent deposit was thought indispensable, and, after three insertions of the knife to the depth of two and a half inches from the swollen external surface, a slight flow of pus was obtained from an opening through the lower lid

and along the floor of the orbit. A thin tent was introduced, and a gradually lessening discharge continued for three or four days, after which recovery was rapid. Very little loss of substance occurred in the orbital cellular tissues, and the normal appearance and movements of the eye were preserved. Loss of vision remained complete. The grayish-yellow aspect of the fundus gradually disappeared, and the only noticeable ultimate changes consisted in a diminished size of the retinal vessels, without the marked blanched and shrunken aspect of the optic disk which is visible in ordinary instances of atrophy of the nerve.

Case II. Mr. G., aged twenty-six, entered my service at the City Hospital April 12, 1882. The history obtained from his physician was as follows: Twenty-five days previously, erysipelas, accompanied by some delirium, had begun in the left cheek, and extended so as to involve the entire scalp, face, and neck, closing the lids of both eyes. There was severe headache, but not much pain in either eye, and no tenderness on pressure. He complained more of the right than of the left eye. When the lids were opened, eighteen days after the attack, the conjunctiva was much congested and the globe was observed to be slightly protruded. The congestion had lessened previous to his admission to the hospital; but there was chemosis towards the inner angle, œdema of the lids, and some protrusion and loss of motility of the eyeball. Slight tenderness on pressure and a little fullness of the upper lid above the inner canthus were also observed. Vision good. A puncture was made at the point of fullness; the narrow knife being passed in to the depth of two and a half inches, and matter, mingled with blood, was discharged. A small tent being inserted, there was free escape of pus during the afternoon and the next day. Late in the afternoon of this day, the eye, which as well as the head had been relieved after the operation, began again to pain him.

On the 14th there had been a free discharge of pus from the wound during the night, but the œdema and tension of the lids was not materially diminished. Another puncture to a depth of two inches was made through the lower lid and along the floor of the orbit, which was followed by a flow of pus. This opening was kept free by the insertion of a tent or by passing a probe, and the discharge continued until May 7th, when it ceased. The movements of the eyeball and vision were normal when he left the hospital, on the 10th of May.

Case III. J. R., aged six, was seen in consultation out of town, July 3, 1882. Two weeks previously he had erysipelas of the face, eyelids, and forehead; but the symptoms subsided, and his physician reports that on the 1st of July both eyes were open and vision good.

When seen, there was no apparent trace of erysipelas. The lids, especially the lower lid of right eye, were much swollen and slightly livid, and as they could not be opened without an elevator, ether was administered to allow of a painless and sufficient examination. The eyeball was then found to be greatly protruded and immovable, and there was much chemosis beneath the conjunctiva covering the lower half of the globe. Cornea clear. I learned that the little fellow had complained of much pain, and said that things looked red with this eye.

The diagnosis of deep-seated orbital abscess seemed to be unquestionable, and with the consent of his physician I introduced Graefe's narrow knife at the inner third of the orbital margin and along its floor, to the depth of two and a quarter inches. Pus followed this puncture, and the external opening being then enlarged, a copious flow of thick matter ensued. A thin muslin tent was pushed into the cavity, and left *in situ* to secure a free outlet, and light poultices were ordered.

I again saw the little fellow on September 14th. Vision was perfect, and only a small scar remained to denote the point of puncture.

Case IV. A man, aged sixty-four, was seen at the City Hospital, in consultation with Dr. Cheever, who kindly allows me to refer to the case, on November 17, 1882. When admitted, November 5th, his face was swollen and eyes closed, and abscesses had already formed in the right eyelids, from erysipelatous inflammation, following a fall occurring some ten days previously. Abscesses were opened in both lids two days after admission, at which time there was much subconjunctival chemosis. On the 12th a small abscess was observed and opened on the cheek, near the outer canthus of the lids. The following day patient could open both eyes, but it was found that he could not see with the right eye. When examined on the 17th he had no perception of light, the optic nerve seemed slightly altered, and retinal vessels lessened in size; there was marked protrusion of the globe, with chemosis, and with steady pain in the eye. Two punctures reaching the bottom of the orbit were made by Dr. Cheever through the upper and one through the lower lid, near the canthi; but no pus followed; only a considerable flow of blood taking place. Relief of pain ensued; but the protrusion, three days afterward, remained nearly the same. December 4th swelling was almost gone, though the conjunctiva was red and puffy, and there was still some prominence of the eyeball. Ophthalmoscopic appearances as before reported. Patient discharged. In this instance the relief of congestion afforded by puncture doubtless averted the process of suppuration; but the pressure of the inflamed cellular tissue upon the retinal vessels had extinguished vision.

Case V. August 29, 1882. I saw in consultation in a distant city a gentleman somewhat advanced in years, in whose orbit similar symptoms and conditions to those I have described, together with loss of vision, had ensued after convalescence from a severe carbuncle upon the neck. Punctures as far as to the bottom of the orbit were made, without finding pus, but with considerable improvement in the local and in the somewhat threatening cerebral symptoms. At a second visit, September 8th, I found the chemosis, protrusion and fixedness of the globe, and the pain continuing. Pneumonic râles were heard over a considerable extent of one lung, and the patient's general condition appeared serious. Deep punctures were again made near the inner and outer canthi without discovering an abscess. Staying for another visit a few hours later, I found that pus had made its way through a small opening in the conjunctiva, between the insertions of the internal and inferior recti. This was enlarged, and a free discharge took place for several days, followed by rapid improvement. The pneumonic râles and fever had disappeared on the 17th.

Some opacity of the cornea and slight shrinking of the globe are reported by his physician as having ensued.

RECENT PROGRESS IN GYNÆCOLOGY.

BY F H. DAVENPORT, M. D.

PERMANENT CURE OF BACKWARD DISPLACEMENTS OF THE UTERUS.

LOHLEIN [1] speaks of the varying views of gynæcologists on this point, some claiming permanent cure in from half to one year, others regarding it a necessity for pessaries to be worn as permanently as trusses. To add to the few observations on this point, the author has selected cases from his own private and policlinic practice. He has excluded all cases complicated by adhesions, all where a too shallow vaginal cul-de-sac or the presence of tumors prevented the complete reposition of the organ, and has included only those in which the uterus was kept in its normal position at least six months, the average being over a year. Only those were considered cured which, on repeated examinations, and at a considerable time after the removal of the instrument, were found to have kept the true position. In accordance with these principles the cases were reduced to fifty-six, of which only four were cured "in the anatomical sense," and fifteen considerably improved.

The influence of pregnancy, and careful attention after confinement in effecting a cure, has, according to Lohlein, been over-estimated. The supposition that the puerperal involution would give to the relaxed utero-sacral ligaments their original tone is not justified by the facts. Lohlein has, in fifteen patients with twenty-one intercurrent confinements, in spite of ergot, douches, and early application of pessaries, effected a permanent cure only twice.

TOTAL EXTIRPATION OF THE UTERUS AND ONE KIDNEY.

Von Stark [2] relates the case of a woman, forty-two years of age, who was the subject of a carcinoma of the cervix uteri, which had also involved the right side of the vagina. He operated for the total removal of the uterus. The operation was difficult, and the right ureter could not be separated from the diseased parts, and finally was cut through. A drainage tube, size of the finger, was left in the wound. Until the third day the patient's condition was good, when fever set in, with pain in the right kidney and escape of urine from the vagina. The wound, which had closed, was reopened and washed out, whereupon the fever subsided. On the sixth day after this the right kidney was extirpated after the method of Simon. There was healing by first intention. Three months later there had been no return of the disease.

SPECIFIC VULVO-VAGINITIS IN CHILDREN AND ITS TREATMENT.

Dr. Richard Pott [3] finds vulvo-vaginitis in children no infrequent occurrence. Among 3921 girls whom he saw in the out-patient clinic at Halle, he found this disease in its most obstinate form in 44. Of these 27 were under five years of age, 13 between five and ten, and 4 from ten to fifteen, showing a tendency to diminish in frequency as the age increases. In all of these cases the purulent or muco-purulent discharge had lasted weeks, in the great majority months. Pott declares that when such disease is present, in ninety per cent. of the cases the mother will be found to have a specific vaginitis. The infection can be communicated at birth, but the genitals are much less exposed to the infection than the eyes, hence blennorrhœa is much more common with the new-born.

In the case of older children, the custom which obtains with the poorer classes, of children sleeping with their parents, favors materially such infection, and the reason why girls are so much oftener affected than boys lies in the fact of the much more exposed situation of the mucous membrane in the former than in the latter. In only two cases could attempted rape be charged as the cause.

Six cases of the whole number depended upon congenital syphilis. In a very few cases the presence of some foreign body was the cause, but not once was the much accused oxyuris vermicularis found.

Pott recommends in all cases the ocular inspection of the parts affected, as well as the digital exploration, and the use of the speculum. That the hymen is ruptured by such examination he considers a benefit rather than otherwise, as treatment which was fruitless with an intact hymen speedily showed good results when that membrane had been ruptured. As speculum he uses a small nasal speculum, and light is thrown in by means of a head mirror.

In addition to the purulent discharge there are apt to be shallow ulcerations on the labia majora, eczema of the surrounding skin, and swollen inguinal glands. The effects on the general health vary according to the stage of the affection. In the very earliest stage of acute infection there is considerable febrile disturbance, symptoms of cerebral excitation, sleeplessness, and even muscular twitchings. These disappear in a few days, and then for months the purulent discharge may continue without the general health being much affected. Later the children become anæmic, look pale or sallow, the nutrition suffers, and a nervous excitability becomes manifest.

The longer the affection has lasted the less easily does it yield to treatment. In the most chronic cases both injections and applications, with a brush, of astringents and other medicinal agents failed completely. This has seemed to the author to depend in many cases on the fact that the vaginal secretions had no free exit, owing to the small hymeneal opening, and pus collected in considerable quantities behind the membrane. He was led to this opinion by observing that in cases where the hymen was torn by the introduction of the finger, improvement followed rapidly.

A method of treatment, however, which the author has employed with most brilliant results in a very few recent cases, may render this harsher method superfluous. Iodoform, either blown in in form of powder, or applied in the form of bougies of the size of a thin lead pencil, has cut the affection short as if by magic. Of twelve cases treated in this way in only two was it necessary to repeat the application. In no case did a relapse occur.

DRAINAGE IN PERITONEAL OPERATIONS.

A. Martin, of Berlin, in this brochure,[4] combats the principles laid down by Bardenheuer in favor of peritoneal drainage. He first shows from some cases in his own experience that the absorptive power of the peritonæum is practically unlimited, and that its tolerance is very great. The farther argument of Barden-

heuer with regard to the leaving of large wounded surfaces in the peritoneal cavity, Martin replies to by saying that it is usually possible to cover such wounds in one or another way with peritonæum, and so shut them out from the abdominal cavity. Antiseptic treatment is presupposed.

Martin gives as exceptions, first, those cases where portions of tissue already suppurating cannot be removed at the operation, and second, cases in which it is impossible to avoid a communication between the peritoneal cavity and the vagina, as in the case of the cyst wall of extra-uterine pregnancy and in extirpations of the uterus. Under these circumstances Martin favors primary drainage, which, in the case of remaining cyst walls, he carries out in this way, that he establishes a communication between the deepest portion of the cyst and the vagina, and completely cuts off the upper portion from the peritoneal cavity by sutures. In four cases treated in this way the result was excellent.

In cases of the second class, primary drainage was employed twenty-two times, but in only a part of the cases was the drainage tube used for washing out the lower part of the pelvic cavity. Martin has never seen favorable results from drainage of the peritoneal cavity after septic absorption has taken place.

RELATIONS OF THE THYROID GLAND TO THE FEMALE GENITAL ORGANS.[1]

The author of this interesting and important dissertation confines himself entirely to those enlargements of the thyroid which result from congestion and simple hypertrophy. Such swelling may be found in fœtuses and new-born infants as a result of congestion at time of birth from faulty position (especially face and forehead presentations) and tedious labor, and has very little importance, as it disappears quickly. Occasionally the affection seems to have begun in fœtal life, due to hereditary or endemic causes, and in such cases the prognosis is bad, very few children surviving. Four cases were reported from the Strassburg Maternity Hospital, three of which were interesting on account of the treatment employed. To prevent the violent attacks of dyspnœa, which are the result of the pressure of the tumor, the head was brought into hyperextension by a roll placed in the nape of the neck. The dyspnœa was relieved, and in a few days a shrinking of the gland could be observed.

That there is some connection between the thyroid gland and the female genital organs has been known for a long time. At the time of puberty a swelling of this gland often occurs in both sexes, especially the female. It is a congestion undoubtedly due to the quickened circulation noticed at this time in various organs, similar to the momentary enlargement of the thyroid during sexual excitement.

During the menstrual period as well is there, in some persons, a swelling of the gland, and the degree of enlargement may correspond to the amount of the menstrual flow. Most of the permanent enlargements begin during menstruation, and disorders of this function, especially amenorrhœa, lead to swelling of the thyroid.

During pregnancy there is almost constantly an enlargement. Of fifty examined by Freund on this point only five were found to be free from it. It may become so large as to give rise to alarming and even fatal suffocation. During labor an average increase of one and one half centimetres was found, which disappeared in from twelve to twenty-four hours. The increase observed during pregnancy also gradually disappeared in the course of a few weeks, and in half the cases only was there any increase during lactation. Freund has had no opportunity to observe whether senile involution of the genital organs inclines to hypertrophy of the thyroid, a fact which is maintained by some.

Very little is known about the pathological relations of the two. Basedow's disease is an exception. This affection, in which an enlargement of the thyroid is one of the most constant appearances, is much more common among women than men, develops almost without exception during the period of sexual activity, and particularly during pregnancy, and the trouble may disappear after confinement. The father of the author found in all cases of this affection which he observed the so-called parametritis chronica atrophicans.

FREQUENCY OF DISEASES OF THE SEXUAL ORGANS IN INSANE WOMEN.

Dr. Danello[2] examined two hundred insane women, and found that one hundred and sixty-two, or eighty per cent., were suffering from various diseases of the sexual organs. Out of one hundred and forty menstruating women, between fifteen and forty-two years of age, only twenty were without some uterine anomaly. Of sixty women who had ceased menstruating, between forty-two and seventy-five years of age, eighteen had some lesion of the genital organs. The most common forms of disease were acute and chronic endometritis and metritis, then displacements of the uterus, dysmenorrhœa, acute and chronic ovaritis. These results show that the complication of mental disease with uterine disease is extremely common.

EXTIRPATION OF THE UTERUS PER VAGINAM.

Professor Czerny,[3] of Heidelberg, claims that when extirpation of the uterus by abdominal section had, on account of its great mortality, lost credit with the profession, he showed that the operation per vaginam would in many cases give better results. The reasons are that the boundaries of the disease are better made out from the vagina, wounding of bladder and ureters more easily avoided, the danger of shock from exposing the bowels lessened, and the danger of septic infection of the peritonæum by the cancerous masses not so great. Czerny has collected eighty-one cases of vaginal extirpation of the uterus, and gives the results as follows: Of the whole number fifty-five recovered, and twenty-six died, giving a mortality of thirty-two per cent., while Hegar and Kaltenbach give seventy-one per cent. as the mortality following the abdominal operation of Freund. To show what may be done by a careful selection of cases, the author cites the experience of Olshausen and Schroeder, who, out of fourteen, lost but one, and that from primary hæmorrhage. Then follow the histories of nine cases operated on by Czerny, three of which died from sepsis. Czerny describes in full his method of operating, and at the end gives the following indications:—

The vaginal extirpation (colpo-hysterotomy) is especially indicated for carcinoma of the cervical canal as long as the uterus is movable and not particularly enlarged, and the pelvic outlet of normal size. To

[2] Deutsche Med. Zeitung, No. 18, 1882.
[3] Berl. klin. Woch., Nos. 46 and 47, 1882.

reach it better the perinæum may be divided in the median line, and later sewed up.

The supra-vaginal amputation of the cervix is indicated in the cases of papillary and ulcerating carcinoma of the cervix when the disease has not reached the internal os. Even if it has affected the vaginal cul-de-sac, that is no contraindication if the uterus is movable.

The abdominal method (laparo-hysterotomy) is indicated when the uterus is movable with difficulty or much enlarged, or when there is a contracted pelvis, provided we may hope to remove all the disease by the operation.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. GEORGE B. SHATTUCK.

REPORTED BY CHARLES D. SAWIN, MEDICAL HOUSE OFFICER.

CASE I. TYPHOID FEVER COMPLICATED WITH PNEUMONIA AND PERIODICAL CHILLS. RECOVERY.

Abrian T., thirty-two years old, a native of Finland, was admitted September 19th, with a history of one week's illness, beginning with headache, epistaxis, and diarrhœa. No cough or other chest symptoms excepting a little shortness of breath. Anorexia and thirst. No rose spots to be seen. Some iliac tenderness, and distension of abdomen. Tongue moist, and covered with a brown coating. Spleen somewhat enlarged with a vertical line of dullness of nine centimetres, and could be felt very easily under the ribs after a long drawn inspiration. Temperature, 102.6° F.; pulse, 104.

Owing to his unfamiliarity with the English language, an incomplete history was obtained; but he positively affirmed that he had a severe rigor two days previous to his admission to the hospital. Examination of chest showed nothing abnormal beyond a few sonorous râles in both backs. On the next day two or three doubtful rose spots were seen on abdomen.

A well-marked chill this forenoon (20th,) at ten o'clock, followed by a rise in temperature to 103.5° F. A subcutaneous injection of five grains of quinia undoubtedly mitigated its severity somewhat. Five grains of quinia were then given daily at four or five o'clock A. M.

On the 21st another chill at eleven o'clock, but of less violent character. Sponge baths every two hours when the temperature is above 102° F.

September 22d. Patient was taken with a violent cough, accompanied by little or no expectoration. Numerous sonorous râles were heard all over left front, and slight dullness and fine moist râles on both inspiration and expiration over a small area just below and to inside of lower angle of left scapula.

September 24th. Cough very distressing; no expectoration; complete flatness over lower left back, with numerous crepitant râles on inspiration alone; bronchial respiration quite well marked; sonorous râles as before mentioned; cotton jacket applied; cough mixture *pro re nata*; baths and quinia omitted.

September 25th. This morning temperature was 103° F., and ten grains of quinia were given by cachet. More comfortable on the 26th. Patient had no stimulant till the 29th, when the pulse, which was not very frequent, became perceptibly weaker. Brandy, one half ounce, every four hours.

October 1st. Dullness at lower left back with the returning crepitant râles; broncho-vesicular respiration and diminished vocal fremitus; general condition much improved; no diarrhœa; tongue quite clean; diet increased.

October 6th. Only a small area of dullness at lower left back, where are heard crepitant and a few fine moist râles; sputa thin and serous.

October 16. Percussion of chest normal; few fine râles in left back; brandy omitted.

Discharged well on the 17th.

CASE II. PERITYPHILITIS. DEATH.

Dr. F. W. Draper on duty.

F. K., forty-seven years old, always enjoyed good health till five days before coming to the hospital, which was on the 27th of August. The attack began with a severe pain in right iliac fossa, which subsequently extended over the whole abdomen, and was accompanied with almost constant bilious vomiting; anorexia; no dejection for four days past; no epistaxis; tongue coated, brown, and parched; temperature, 98.7° F.; pulse, 100; urine high colored; acid, specific gravity, 1022; chlorides diminished, with a trace of albumen; sediment not abnormal. Sol. magendie, four minims every two hours, *pro re nata*, for relief of pain; brandy, one half ounce, every hour and a half; poultice every four hours to right inguinal region; some difficulty in voiding urine, and catheterization became necessary.

August 28th. Vomited three times during the night, but at longer intervals than on yesterday; hands cold and clammy; pulse small and feeble; abdomen tympanitic, especially in right side; less pain; one dejection this morning; morphia and hot applications continued. August 29th. Still in a critical condition; almost pulseless; abdomen much distended; occasional vomiting of bilious fluid; continues to remain under the influence of morphia. August 30th. A little gain; pulse can be counted at wrist; less tympanites; extremities warmer; later in the afternoon, however, signs of collapse were exhibited quite suddenly, and incessant vomiting set in, followed by much intense abdominal pain, which soon ended fatally.

Autopsy by Dr. W. W. Gannett.

Abdomen enlarged. Omentum adherent to the folds of intestine. Intestine distended with gas, with the folds adherent to one another. Outer surface not lustrous, but in some places was covered with an abundant fibrinous false new membrane. "Between the folds of the intestine and pelvis, and right iliac region, there was, in addition to the fibrine, a considerable amount of creamy pus. The first fifteen millimetres of vermiform appendix was pervious, and large enough to admit the tip of the little finger, the remainder of the lumen being impervious. There was a perforation of the vermiform appendix just at the end of the cul-de-sac described, and just to the outside of the opening lay a ragged block of fæcal concretion about the size of the finger. This lay in a pool of pus. In its neighborhood the inflammatory signs were most marked. Mucous membrane of intestine showed nothing unusual."

CASE III. MEMBRANOUS DYSMENORRHŒA [?].

Dr. F. W. Draper on duty.

Margaret M., thirty-three years of age, admitted to

hospital August 2d, had been married eleven years, and during this period had had two children, and three or four, perhaps more, supposed miscarriages. The first child was delivered by means of instruments about nine years ago, and there resulted a slight perineal laceration, which was sewed up at the time, and did not rupture again till two years ago, when she was delivered of her second child (still-born). Since the second baby was born her catamenia have been very irregular. No menstrual flow for last two months till a fortnight ago, when she flowed for a single day, but only moderately, and the flow was accompanied by considerable pain. It then ceased, and did not reappear till a week ago. Returned again to-day, but is still slight. Excessive pain in neighborhood of umbilicus two weeks ago. Some pain, though not intense, in hypogastrium to-day; occasional nausea and vomiting; anorexia and headache; micturition normal; constipation; temperature 100° F.; pulse 100; urine normal.

Flowing constant on August 3d.

August 4th. Some vomiting this morning; headache and flowing. Milk and lime water. Ten minims of fluid extract of ergot every four hours.

August 7th. Flowing partially under control.

August 8th. A very copious discharge from vagina, consisting mainly of a shreddy membranous mass of a reddish-gray color, about size of thumb, being cast off without much pain. Flow then ceased altogether, and patient practically well. Discharged on the 10th.

Specimen examined by Dr. W. W. Gannett microscopically, and following report made: —

"Both surfaces" of the mass are "more or less rough, and show a shreddy appearance. It is made up of numerous spindle cells, with short, broad bodies and well-marked nuclei, also very numerous smaller round cells; many portions of tubular glands. *I found no chorion villi.* The above represents the greatly thickened mucous membrane of the uterus, which has been cast off."

No decision was reached as to whether it might be the membrane of "dysmenorrhœa membranacea" or the decidual membrane of early pregnancy.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

JANUARY 8, 1883. DR. J. C. WARREN presided.

DR. HENRY W. WILLIAMS read a paper entitled

ORBITAL CELLULITIS AS A SEQUEL OF FACIAL ERYSIPELAS.[1]

IN answer to Dr. C. P. Putnam, DR. WILLIAMS stated that it is a rare affection. Dr. Putnam asking if any case had been left to itself, Dr. Williams answered, Yes, one case, and it was attended by great pain. Lebert had collected a number of cases and four fifths were fatal. The vessels, before entering the nerve, are compressed, and thus vision is lost without affection of the nerve.

DR. WHITE asked if these cases are likely to follow the deeper seated cases of erysipelas or the wandering, mild form.

DR. WILLIAMS thought usually the deeper seated, but in the child spoken of the erysipelas was of the mild form, this coming as a secondary affection when the erysipelas was passing off.

DR. PORTER referred to a case, seen some years ago, of acute cellulitis of both orbits, following apparently a small sore on one side of the nose. There was no erysipelas, the soft parts were œdematous and infiltrated equally on both sides. He was delirious and was etherized and free punctures made above and below, Dr. Wadsworth being in consultation. Leeches were applied to forehead, and free punctures were made again, but delirium continued, and he died with stertorous breathing after in all four days. The case seemed similar to those following erysipelas. The punctures were carried deeply, undoubtedly deep enough, as it was done with regard to the anatomy of the parts and with the careful assistance of Dr. Wadsworth.

DR. GANNETT asked if any post-mortems were made in the fatal cases. Dr. Williams thought not.

DR. WARREN asked Dr. Williams if there were other causes of blindness in facial erysipelas than those mentioned. In the books this class is frequently mentioned as one of the sequelæ of the disease, and he had acquired the impression that it might occur without a suppurative inflammation having preceded. The presence of suppuration in the cellular tissue in typical forms of erysipelas like these was interesting in connection with the question of identity of phlegmonous erysipelas with true erysipelas. The French writers consider the former as a diffuse cellulitis (*phlegmon diffus*), and not as an erysipelas.

DR. WARREN did not believe that we could abandon the term phlegmonous erysipelas, which could be appropriately applied to a large class of cases familiar to the hospital surgeon.

DR. GOSS reported a case of

CANCER OF THE LEFT KIDNEY AND LUNG.

A gentleman, aged fifty-five, in the spring of 1880, without acknowledging his illness, seemed to his family unwell, and his physician was called. He had some cough, nausea, and occasional vomiting of meals, an anxious expression, and he confessed to not feeling well, though he protested that he was not sick. His own family had been consumptive. An examination of the chest showed nothing abnormal except comparative dullness of the lower part of the left lung, with a want of vesicular murmur; no râles. Nothing could be discovered about the stomach or other parts of the abdomen. Urine, on examination, was normal, as were also the pulse and temperature. He continued to show increasing evidence of sickness, food not seeming to nourish him, and being frequently vomited. The gastric symptoms increased during the spring and summer of 1881, and when at the latter time he went to the sea-shore he was so weak that it was feared the journey might be disastrous to him. While at the sea-shore his stomach gave him less trouble, his appetite improved, and he returned home apparently better, but in a month or two the old symptoms reappeared. He lost flesh and spirits. With great difficulty, but with determination, he went to his business in the city, falling in the street several times from weakness. All through last summer he gradually failed. The latter part of the season his urine began to contain a small amount of albumen and a few casts. The symptoms about the

[1] See page 51 of this number of the JOURNAL.

chest became less marked, but he grew weaker, more emaciated, took to the house, and some six weeks ago to the bed. His urine became more decidedly albuminous and the casts abundant. The abdomen was frequently examined for evidence of disease, — tumor or other —, but until within a few weeks nothing could be discovered. Latterly, however, the suspicion that something of the kind must exist seemed in a measure to be confirmed. Occasionally there appeared to be a tumefaction on the left side about the region of the false ribs, but this was not marked. During the past three weeks he had several convulsive paroxysms, thought to be uræmic. He sank at last from exhaustion, death occurring two days ago.

Autopsy by Dr. Gannett.

DR. GANNETT said that the interest of the autopsy lay in connection with the left kidney and the left lung.

The left kidney was enlarged, perhaps, three times; its external surface lobulated, rather dense. On section very little of the renal substance remained. In its place were numerous nodules about the size of English walnuts, coalescing on their borders. They were of a grayish-white color; some softened in their central portions and more opaque, evidently the result of a fatty degeneration; others showed an opaque-white, firm centre, representing in all probability a coagulation necrosis.

The pelvis of the kidney was considerably dilated, and there existed a growth into it from the previously described mass.

The left renal vein was much distended, and contained a growth extending from the kidney and reaching the inferior vena cava. Ample opportunity was thus afforded for the transfer of portions of the growth by the blood circulation. That such a transfer had occurred was shown by the presence in the lower lobe of the left lung of a nodule similar in character to those found in the kidney, and about the size of a lemon.

Microscopically all the nodules described presented the structure characteristic of the softer forms of cancer.

In reply to a question of Dr. Lyman, DR. GOSS said that there was no evidence of blood in the urine. He also said that there was a family history of phthisis, but not of cancer, but that the so-called cancer cachexia was present.

NEW YORK NEUROLOGICAL SOCIETY.

AT the regular monthly meeting of the Society, held January 2, 1883, DR. S. N. LEO presented patients who had been trephined for traumatic epilepsy, and was followed by DR. L. WEBER, who presented a specimen of occlusion of the basilar artery, after which DR. WILLIAM A. HAMMOND read a paper on

ALLOCHIRIA: ITS NATURE AND SEAT.

On the 4th of November last, Dr. Hammond said he had examined, in conjunction with Dr. L. A. Stimson, a gentleman who was said to have received a severe injury of the spine in February, 1881, from a carriage accident. He was treated for several months for Pott's disease, his condition sometimes being better and sometimes worse, but on the whole there was no decided improvement. The fact that he had brought an action for heavy damages against the city was the immediate cause of his examination by the writer. So far as he could determine from the account given him by the patient, he felt satisfied that at no time had he suffered from injury of the vertebral column or subsequent Pott's disease, and, at all events, he exhibited no symptoms of that affection at the time of this examination. Neither Dr. Clymer, Dr. Hamilton, Dr. L. A. Stimson, or himself could discover indications of its existence. He complained, however, of pain throughout the whole spinal column, and of extreme nervous irritability. He had also had contractions of the muscles of the lower extremities, and when he walked about the room it was evident that his limbs were stiff, and that he lifted his feet with difficulty. The gait, however, was very different from that of a person suffering from locomotor ataxia, as the feet were moved as though weighted with some heavy substance, instead of being raised with a jerk, and put down with the two distinct movements so characteristic of that affection. The knee tendon reflex was greatly exaggerated on both sides.

Up to this time no experiments had been made for the purpose of testing the sensibility of the lower extremities. It was now ascertained that the touch of the finger, the scratch of a pin, and a deep puncture with the blade of a penknife were equally unfelt in the right leg, but when the like experiments were made on the left leg (the patient's eyes being closed all the time) he complained of pain when the knife was stuck into it, and automatically carried his hand to the place which he supposed had been punctured. Instead of touching the spot where the injury had been received, however, he indicated the exactly corresponding situation on the other leg. Repeated experiments led to the same results. He had sensibility in the left leg, but invariably referred impressions received there to the other side.

Dr. Hammond said he then came to the conclusion that the patient was suffering from antero-lateral or lateral sclerosis, with the implication of the posterior horns of gray matter, and probably of the spinal meninges to a slight extent. On this occasion, however, he wished to restrict what he had to say about the case to the phenomenon of crossed sensibility exhibited. To this condition the name of allochiria (from the Greek words ἄλλος and χείρ) had been given by Professor Obersteiner, of Vienna, who was the first to call special attention to it, though the phenomenon had been incidentally alluded to by Leyden, and one or two others as an occasional symptom of locomotor ataxia. Since Obersteiner's article appeared in *Brain* for July, 1881, Ferrier had reported a case (in the same journal for October, 1882,) which followed a severe cranial injury. Of Obersteiner's cases of allochiria four in number, two were of locomotor ataxia, one was hysterical, and one resulted from severe and direct injury of the spine. In the last case the patient died, and post-mortem examination showed that there had been inflammation of the first, second, and third lumbar vertebræ, meningitis, and extensive transverse inflammation of the cord. The posterior columns for a considerable distance above the seat of injury, as described by Obersteiner, were in a state of sclerosis, and the posterior horns of gray matter in portions of the cervical enlargement were transversely divided by a peculiar, structureless, transparent mass, intensely colored by carmine, and very similar to the mass found around the larger vessels in inflammatory processes in

the cord. Dr. Hammond then expressed the opinion that it was to such a lesion of the posterior horns of gray matter that the phenomenon of allochiria was to be ascribed, though neither Obersteiner or Ferrier had offered any explanation of the mechanism of its production. Allochiria was certainly not an ordinary symptom of sclerosis of the posterior columns, and he did not believe that it was ever met with in uncomplicated cases of this affection. He did not, indeed, believe it a possible condition in such instances.

For the better understanding of the subject he thought a few words regarding the anatomy and physiology of the cord would be of service. The posterior tract of gray matter, he said, was probably the only channel by which sensory impressions reached the brain; but before reaching the posterior horns the posterior roots of the spinal nerves passed through the columns of Burdach, and when these were the seat of inflammation, as was the case in locomotor ataxia, disturbances of sensibility were produced in the parts below, by the pressure exerted upon these roots. It was quite certain, as claimed by Brown-Séquard and other authorities, that there was an almost complete decussation of the sensory fibres within the gray matter; those from the right side of the body passing over to the left side of the cord, and *vice versa*. Dr. Hammond illustrated this by a diagram, and showed that a lesion of the right posterior horn would produce anæsthesia of the left side of the body, and *vice versa*. He then went on to say that in sclerosis of that portion of the posterior columns called the columns of Burdach the lesion was almost always symmetrical, and, as a consequence, we had in the latter stages more or less profound anæsthesia and retardation of the conveyance of sensory impressions in both lower extremities. Allochiria was in such cases an impossibility; for, all channels to the brain being closed, wholly or in part, the patient either had no sensation or very imperfect sensation in the parts below, and equally on both sides. But in cases of disease or injury of the posterior horns of gray matter, whether primarily or secondarily involved, in which allochiria existed, it was essential either that the lesion should be unilateral or, if both horns were involved, that the lesions should be at different levels. This was also made more evident by means of a diagram. Thus it was seen that if there were a lesion in the left posterior horn a sensation coming from the right side of the body would be directed through the gray commissural fibres to the right posterior horn, and would reach the cortical centre in the right hemisphere, which was in relation with fibres coming from the left side of the body. The crossed sensations resulting would constitute the condition of allochiria, in which all sensations made, for instance, on the right side of the body would be felt on the left; while those on the left side would be felt in their proper situations. But if it were supposed that there was another lesion symmetrical with that at the point above indicated, it would be evident that no sensoid impressions from either side could reach the brain. If, however, the second lesion were at a point lower down than the first, the impressions coming from the right lower extremity would be diverted to the left side on reaching the obstruction, and then reaching the obstruction higher up on that side would either be altogether interfered with, leading to complete anæsthesia of the left lower extremity, or would be again diverted, and reaching the right hemisphere of the brain, though with their strength greatly diverted, would be imperfectly felt in the left lower extremity. Such lesions explained those cases in which there was absolute anæsthesia on one side of the body, with sensation on the other side for impressions coming from both sides. They also showed, as Obersteiner had asserted, that anæsthesia was not a necessary concomitant of allochiria. In the only case of allochiria in which a post-mortem examination had been made, namely, the fourth case of Obersteiner, it was found that among the other abnormal conditions disease of both posterior horns of gray matter was present. The morbid process was not continuous, however, as it was stated that it was not perceived in all the sections. It was situated at the narrowest part of the posterior horns, being so placed as to interrupt the decussation of all the nerve fibres, and hence to cause the transmission of sensory impressions upward on the side in which they entered; a condition, which, equally with that which the writer had described, would give rise to allochiria.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, RECORDER.

Thursday Evening, December 28, 1882. The President, Dr. Tyson, in the chair.

TUBERCULOSIS OF SPLEEN, LIVER, AND KIDNEYS.

Exhibited by Dr. Shakespeare.

These specimens were presented without a history of the case, and showed exuberant vegetations in pericarditis, abundant miliary tubercles of the pleura, of the spleen, of the liver, of the kidneys, and of the lymph glands in the region of the head of the pancreas. The subject came from the medical wards of the Philadelphia Hospital, and was last under your care, Mr. President, as visiting physician. They are brought to the notice of the Society mainly because the autopsy was made this P. M., and because many of the members have not had opportunities of examining such perfect examples of extensive and diffuse tuberculous infiltration without more serious involvement of the parenchyma of the lungs.

Autopsy, six hours after death, of C. J., colored, aged sixty. Diagnosis: pericarditis and pleuritic effusion, with strong bands of adhesions between parietal and visceral pleura. Thorax: Left pleural cavity completely obliterated by adhesions. Right pleural cavity contained a large amount of straw-colored serum. The lobes of this lung were compressed against the spinal column, and were atelectatic. The lower lobe was firmly adherent to the diaphragm, and the three lobes were strongly united by adhesions. The parietal pleura was thickened and everywhere studded with minute gray, semi-opaque miliary tubercles; the visceral pleura was in a similar condition, except that the tubercles were less numerous. The cut surface of the right lung presented nothing abnormal save absence of air, but the sense of touch showed beneath and near the pleura a few scattered minute points, much smaller than millet seeds. The pleura of the left lung was also studded with numerous miliary tubercles, and the tissue of this lung was similar to that of the right. It was, however, crepitant. The pericardial sac contained two and a half ounces of straw-colored serum. The whole heart was covered with an

exuberant crop of vegetations. The cardiac walls were, perhaps, slightly softer than usual; otherwise normal. Abdomen: Peritonæum normal, no effusion. Liver slightly enlarged, with surface here and there raised by flat elevations, ranging in size from a hempseed to that of a hazel-nut; capsule normal. The nodules were firm and of a yellowish tint; the intervening tissue was of a dark red. Section of the organ deeply revealed similar nodules diffused through its substance, which seemed otherwise firm and normal. The spleen was slightly enlarged, firm, and extensively infiltrated with tubercles. The pancreas was normal, but the lymph glands near it were much enlarged, but neither softened nor caseous. No caseous focus was anywhere detected. The kidneys appeared normal except for one or two more or less pyramidal yellow points. This case presents several points of interest: (1.) Former history unknown. (2.) Several aspirations, removing considerable pleuritic fluid. (3.) What was the origin of the numerous tubercular irruptions, and, if there was auto-infection, what was its probable source? Dr. Tyson then gave a *résumé* of the ante-mortem history.[1]

DR. TYSON said he regretted having to admit that he was less familiar with the history of the case than he should have been, since the patient was in his own wards in the Philadelphia Hospital. It had been previously thoroughly studied by Dr. Bruen, whose absence he regretted, as Dr. Bruen knew so much more about the case. The man had, however, been more than once tapped. He was a colored sailor, aged sixty years. When Dr. Tyson took charge of the ward, in September, the man presented the physical signs of double pleuritic effusion, orthopnœa, feeble transmitted heart sounds, but no cardiac murmur. There was œdema of the legs. He was tapped with great benefit, and under a restorative treatment he rapidly improved, so that he soon became one of the walking cases in the ward, attracting little attention. About December 1st he became very much worse. The orthopnœa and other signs of accumulating fluid returned, and so did the œdema of the legs. His urine was repeatedly examined for albumen, with negative results. He was tapped upon the right side, and three pints of fluid removed, with but partial relief. The other side was also aspirated without success. A cardiac friction sound was noted, which seemed to be pleuro-pericardial, but in the light of the autopsy it was probably pericardial. He died on the 13th of December. With reference to the case cited by Dr. Formad, it had also seemed to be a simple plastic pleurisy with feeble, distant heart sounds, with no murmurs occurring in a case where, after prolonged illness, death resulted from exhaustion. Dr. Tyson had never seen such extensive new formations resulting from serous inflammation, the large lymphoid masses in the abdomen having at first suggested the idea of malignant disease. The patient had a distinctly scrofulous history. The father had died after pleurisy with cheesy deposits, followed by miliary tubercles of the lungs later in life. Four or five uncles and one aunt had all died phthisical between twenty and thirty years of age.

DR. BARTHOLOW asked if the range of temperature accorded with that usually found in phthisical cases.

[1] Dr. Formad here related a case of general tuberculosis, and showed the specimen, but no notes having been forwarded to the Recorder any fuller account than the remarks of Dr. Tyson is impossible.

DR. TYSON said that in the case related by Dr. Formad the temperature was seldom if ever above 101° F., mostly below this point. In the case reported by Dr. Shakespeare he was unacquainted with the temperature record.

DR. NANCREDE demurred to the view that repeated tapping had any causative relation to the development of tubercle after pleurisy, but thought that the chronicity of the affection and altered condition of the pleural sac, which demanded frequent operations, were the real explanations of the alleged fact.

DR. MUSSER said that a relationship between pleurisy and pulmonary tuberculosis could not be denied, but whether the pleurisy or the tuberculosis be antecedent was difficult of solution. That the former is primary may be inferred from the fact that persons are considered as threatened with phthisis who have subclavian arterial murmurs, due to the pressure or pulling on the artery of organized lymph. Likewise are the various friction sounds and exocardial murmurs noted to precede tuberculosis, and especially to occur in those tuberculously predisposed. Examples of both cases have come under his observation. It seems to him that a primary acute pleurisy is a rarity, occurring in a non-tubercular subject. The last series of cases of what would be called primary pleurisy he had seen were in persons predisposed to tubercle, and in some of the cases tubercle subsequently developed. In short, so-called primary plastic pleurisy occurs only in tuberculously disposed individuals; other forms are secondary to some other process, as Bright's disease, septicæmia, etc. Trousseau calls attention to latent pleurisies with effusion as being often an expression of a tuberculous diathesis, while also a latent pleurisy may occasion development of that diathesis. Two cases illustrating these views have lately come under his notice.

DR. O'HARA said that although he had not had much experience with latent pleurisy, he recalled a case of a young man seen five years ago, where extensive effusion into one side of the chest had unsuspectedly occurred, and when detected had been removed by tapping. Apparent recovery then ensued to be followed, in a few weeks, by copious effusion into the other pleural cavity. Tapping was again resorted to; the effusion never recurred, and the patient remains healthy and free from tubercle at the present time. He would like to ask if, when the term "all the serous membranes were affected" was used, those of the brain were included.

DR. TYSON replied that there had been no head symptoms in the sailor's case. In that mentioned by Dr. Formad decided mental aberration, demanding watchful restraint, had been present. No inflammation of the meninges had been found, the only disease consisting of a small tubercle starting from the pia mater and dipping down into the brain substance.

DR. SHAKESPEARE closed the debate by referring to the causes of tuberculosis in general and its mode of diffusion through the organism. He called attention to the failure in discovering any caseous focus, while admitting the possibility of such, if minute, escaping the most painstaking search. In this and similar cases all that could be safely said was that *the caseous point was not found.* Assuming, for illustration, that the point in the kidney might have been the origin of the auto-infection in this case, he referred to the communication between the left renal vein and the

inferior mesenteric vein, and the direct communication with the portal system thus effected. As to the point raised by Dr. Musser, he believed in plastic pleurisies distinct from tuberculosis. He had examined very many microscopic sections of pleuritic adhesions, and very many had proved to be free from tubercle. Authors who have made original investigations on man and the lower animals have also as distinctly recognized a plastic pleurisy *without* tubercle as they have one associated with this formation. He thought tapping in a person not predisposed to tubercle was no more likely to produce this disease than tapping an anasarcous limb. He was well aware of the facts dwelt upon by Drs. Musser and Formad, namely, the association of tapping with tuberculosis, and of plastic pleurisy with tuberculosis, but he believed that the frequency of this association had been exaggerated. He thought that in view of the well-grounded belief that in certain classes of animals, as well as in certain families of men, inflammation tends to linger, to produce accumulations which are prone to degeneration, and to *excite* local or general tuberculosis, it is more logical to conclude that in such cases as above mentioned there is at the outset a tainted constitution, — a soil already sowed with the dormant seeds of disease waiting to be awakened to their active processes of destruction by the stimulation of an exciting cause. The more frequent the action of the exciting cause the more certain is this dormant tendency to be aroused. [Dr. Shakespeare then proceeded to combat the views advocated by Dr. Formad in this debate; owing to their non-reception by the recorder Dr. Shakespeare's remarks are also of necessity omitted.]

TWO CASES OF CARCINOMA OF THE STOMACH.

Exhibited by J. H. Musser, M. D.

Case I. Scirrhus of the pylorus; general proliferation of the connective tissue; interstitial nephritis. Malignant disease of the pylorus and of the lesser curvature of the stomach was diagnosticated when the patient applied at the Medical Dispensary of the University Hospital, May 14, 1882, for treatment, on account of the physical signs especially and of some points in the clinical history. Palpation and percussion revealed a firm, non-pulsatile, immovable, slightly painful tumor in the middle of the epigastric region, one inch to the left of the median line, about the size of a turkey egg. When lying down the abdomen was slightly scaphoid; but the left upper quarter was distended. A curved line extending downwards from the umbilicus to the flanks represented the lower limit of this swelling, which was soft and resistant, tympanitic on percussion, and with care could be discerned as starting from the hard tumor in the epigastrium. In short it was due to a distended stomach. Although the tumor was not in the position of the pylorus, and although the patient had never vomited, yet pyloric disease was determined upon because of the gastric distention. On account of the absence of marked obstruction, the position and the occurrence of pain in the *lumbar* region, disease of the lesser curvature and the posterior wall was decided upon. The autopsy revealed that the malignant growth surrounded the stomach at the pyloric end, but was greater in extent in the lesser curvature. An adhesion to the left lobe of the liver explained the position of the tumor. The patient first noticed the localization of the disease in November, 1881, by the occurrence of pain in the epigastrium following a jar. She noticed that her health had failed three months before, and that menstruation had ceased six months previous to the epigastric pain. Note here the failure of health before any local evidences of disease, not even dyspeptic symptoms. She was a widow, aged forty years, with one child; her health had always been very good; her circumstances moderate, and her habits exemplary. In addition to a constant burning pain, increased by food, her appetite was poor, tongue pale, with enlarged papillæ; flatulency was marked, and the bowels constipated. She presented a sallow, cachectic appearance, was somewhat emaciated, extremely anæmic, with cardiac, arterial, and venous blood-murmurs, and accentuated second-sound. She was under observation until her death, October 17, 1882. The pain and constipation were relieved by treatment, but the course was only downwards. In addition I may note the cachexia became more marked, and the classical appearance of the face was wonderfully depicted — transverse and vertical lines on the forehead, and semi-circular lines around the mouth from the alæ of the nose to the chin and vertical lines on the chin and lower lip. The hue of the countenance changed, growing darker and darker. This peculiar hue of the face Dr. Musser considered the most reliable symptom of approaching dissolution. It was noted one month before death. During the last two months of her illness she suffered much from soreness of the mouth and tongue without visible lesions; from burning in the fauces; difficulty of deglutition; acidity; vomiting taking place every third or fourth day, of a clear, acid fluid, coagulated milk, bile-stained, and "coffee-ground material." A painless, watery diarrhœa occurred frequently with tarry masses. Œdema of the feet and ankles took place six weeks before death. The tumor grew in size and changed position, falling downwards. Three days before death it was noted to pulsate, was tender, and was three inches long, extending from the median line to the left on a level with the umbilicus.

Autopsy twelve hours after death. Extreme emaciation; rigor mortis marked; œdema of feet. Heart slightly enlarged, the left ventricle walls eight and three fourths lines in thickness; heart weighed seven ounces. Aorta one inch, one and three fourths lines in diameter, and slightly atheromatous. Deposits of fat along the septum were noted, and the muscular tissue itself was fatty. The stomach was in the position defined a few days before death, was greatly dilated, with the disease at the pyloric end extending along the lesser curvature four, along the greater curvature two, inches, and completely encircling the organ. The stomach walls became thickened with much hypertrophied muscular coat as they approached the diseased area. The internal surface of the tumor was flat, elliptical, and defined by an everted lip of varying thickness about four lines high. The surface was uneven, some nodules being half an inch thick. The most central portion presented distinct evidences of ulceration.

The liver was rather larger than normal, seemed fatty, and was not indurated. The kidneys were small, hard, and the capsule peeled off with difficulty. Microscopic examination of the stomach, liver, and kidneys, Dr. W. E. Hughes assisting, showed abundant irregularly-shaped epithelial cells packed closely in a fibrous stroma, but slightly developed in and containing numerous nuclei. Liver cells fatty and pigmented. Proliferation of the connective tissue around the he-

patic and portal veins was noted, many nuclei proving its recent origin. The kidney was markedly cirrhotic, the connective tissue being *not* of recent formation. Note the general proliferation of connective tissue in the organs. No albumen was detected during life in the urine, nor were any renal symptoms noted; yet there was undoubted interstitial nephritis belonging to the variety described by Gull, Sutton, and Mahomed. The mal-assimilation consequent upon the gastric lesion was the predisposing factor in the production of this general change.

(*To be continued.*)

Recent Literature.

The Pharmacopœia of the United States of America. Sixth Decennial Revision. By Authority of the National Convention for Revising the Pharmacopœia, held at Washington A. D. 1880. New York: William Wood & Co. 1882. Pages xliii., 488, 8vo.

This so long looked for work has at last appeared. Yet even this so much later date than was expected by the Convention is earlier than the publication of the two previous revisions, which involved but a very small fraction of the labor that has been spent upon this, the most thorough of all the revisions; this unusual promptness being principally due to the unremitted toil of the most efficient chairman of the Committee on Revision, Dr. Charles Rice, of New York city, who has been ably assisted by most of the other twenty-four members. To each of these, as well as to some few other volunteer aids, he sent some hundred and seventy circular letters upon the revision.

The time taken for this, the last revision, has thus been but a little over that taken by Drs. James Jackson and John C. Warren, of Boston, for the preparation of the first American Pharmacopœia, that of the Massachusetts Medical Society, which was ordered by a vote of the Counselors on October 3, 1805. Their manuscript copy was presented June 5, 1807, and the published work had the certificate of Drs. Jackson and Warren, dated December 17, 1807, that it was printed therefrom agreeably to the vote of the Counselors; yet the publishers, according to the even at present not uncommon custom, place the date of the new incoming year 1808 upon the title-page, that the work may appear to be as recent as possible. Thus the Massachusetts Medical Society published not only the first American Pharmacopœia, but they also made the first known effort for the preparation of a National Pharmacopœia. For, according to vol. ii., page 266, of the Medical Communications and Dissertations of the Massachusetts Medical Society, published by the Society at Boston, 1813, "after its publication a copy was sent to the different medical societies, with a circular letter requesting them to examine the work, consider in what respects it needed alterations or amendments, and expressing a desire that some means might be devised to establish a standard work for the United States." This last fact, as thus stated in the official publication by the Society of the historical dissertation read by Dr. Josiah Bartlett at the annual meeting of the Society in Boston, June 6, 1810, is of especial interest on account of the usually allowed claim made in the historical introduction to the first edition of the Pharmacopœia, of which Dr. Lyman Spalding, of New York, was himself the chairman of the Committee of Publication, and repeated in the revisions, that the American Pharmacopœia owes its origin to his project submitted to the New York County Medical Society in January, 1817.

Among the very many important changes made in this revision, of which every physician as well as pharmacist should possess a copy, as it is now in this and some of the other States the legal standard of strength, quality, and purity of all drugs and their preparations which are mentioned therein, the following are some of the more important: All the titles are arranged in one continuous alphabetical list, retaining, however, the several class headings. All measures of capacity have been abandoned except in the case of the fluid extracts; all quantities otherwise being expressed in parts by weight. Most of the fluid preparations have been reduced to some more simple uniform decimal percentage of strength. The nomenclature has been revised on the basis of certain general principles. The botanical genus name of a vegetable drug is the official Latin title, and is to denote the part to be used if there be but one; otherwise the part forms a portion of the title. It will also usually form the English title. The Latin titles of the alkaloids are to end in *-ina*, and the English in *-ine*, while the so-called neutral principle will end in *-inum* and *-in*. The Latin nouns in *-as* and *-is* now again are given their proper masculine gender.

This revision, however, still uses the incorrect term officinal where official should be used. All drugs in a pharmacy which are in accordance with the customary usages of the shop (*officina*) are officinal, while those only of them which have been prepared in accordance with the authority of the Pharmacopœia are official. Even all proprietary medicines are officinal but they certainly are not official.

Alum once again denotes the potassium salt. The strength of the fluid extracts have been reduced about five per cent. Yet the most important change in the strength of any of the preparations is that in the tincture of opium, which has been increased in its morphine strength from thirty-three to seventy-seven per cent., or upon an average about fifty per cent. Especial notice of this important change should be taken by all physicians and pharmacists when prescribing or dispensing this preparation.

In this connection the Committee upon the Revision have made a very important omission in neglecting to make any provision or even any mention as to when the new revision was to go into full legal effect. It would have been well, following the example as to the Pharmacopœia in other countries, to have appointed some date, such as January 1, 1883. In the absence of all such mention it cannot be considered otherwise than to have gone into effect immediately upon its first appearance, as there can well be but one Pharmacopœia of the United States.

The new classes of preparations that have been introduced are the abstracts, triturations, tinctures of fresh herbs, and a single elixir.

In this revision 229 of the former titles have been dropped, while 256 have been added, making 997 titles in all. As an example of the thoroughness of this revision, and of the additions made, fourteen of the new preparations are of iron alone. Among these are ferri carbonas saccharatus, an excellent form for administration, especially to children. The tinctura ferri chloridi is now directed to be kept for at least

three months to secure the development of the proper ethereal character. The ferri iodidum saccharatum has been introduced that an unchanged syrup may be readily made when needed by solution in its own weight of water, while the ferri oxidum hydratum cum magnesia has been introduced for the purpose of having on hand an *immediate* antidote in cases of arsenic poisoning. This mixture when made, containing the hydrated ferric oxide and magnesia sulphate, with a trifling excess of the magnesia, is to be administered at once without any washing of the precipitate, as its taste and contents are entirely unobjectionable. The newly introduced tinct. ferri acetatis has long been a favorite upon the Continent. Syrupus ferri quininæ et strychninæ phosphatum is the new official preparation to replace the many formulæ known as "Aitken's" and "Easton's" syrup of the triple phosphates.

Appended to the work is an extended list of test reagents, volumetric solutions, and tables. These are of especial importance now that all drugs are required by law in this State to conform to certain standards of strength, quality, and purity. As all those bearing official titles must correspond to the standards of the Pharmacopœia it is important that the methods of ascertaining this should be contained in that work itself. Some few of the tables, however, to be inserted in the work, according to the instructions of the Convention, could not be prepared in time to appear in this the main body of the work. It is expected that they will be inserted in a subsequent supplement to the Pharmacopœia. As an aid to the subsequent revision all interested persons are requested to report to the chairman of the Committee before January 1, 1884 and 1889, a list of those articles and preparations which have not been prescribed at all, those but very seldom, and also any objections suggested by experience to the practical working or observance of the methods directed in this work.

The book has but very few typographical errors, considering the nature of the work. The printing and paper are excellent, and the binding good.

With such an extended official list from which the physician can draw his arms for fighting disease, with such full and minute directions furnished to the pharmacist for choosing and preparing them of the proper strength, quality, and purity, with a stringent State statute requiring all drugs to conform to their proper standards, with an active officer employed by the State to examine into and see to it that all this last is done, there is now very little excuse upon the part of the physicians of this State at least for prescribing the preparations of any particular proprietary make. They need simply to indicate the drugs of which they wish to make use, leaving it to the educated pharmacist to make their selection. They can thus only hold him as strictly responsible under the law for the strength, quality, and purity of that which he dispenses.

B. F. D.

Diseases of the Ear in Children. By ANTON VON TROLTSCH, M. D. Translated by J. ORNE GREEN, A. M., M. D.

This valuable work is well worthy of the evident care bestowed upon its translation. It presents plainly and with sufficient elaboration the details of a subject of more importance, in one sense, to the general practitioner than to the special student, since in a great majority of cases of ear disease in children it is the family physician and not the aural specialist who has to deal with them at first hand, and to whom comes the responsibility of administering that ounce of prevention which outweighs the pound of cure.

The book treats, in Chapters I., II., and IV., of diseases of the external, middle, and internal ear respectively. Chapter III. is devoted to the consideration of foreign bodies in the ear, and Chapter V. to the subject of deaf-mutism.

Each of the three chapters first mentioned begins with a short enumeration of the malformations, and then proceeds to a description of the diseases of the respective divisions of the ear and their treatment. Of the 165 pages, 102 are devoted to diseases of the middle ear, a justifiably large proportion of the work, since, as the author says, "It may be asserted as a fact that in childhood, aside from a few weeks immediately following birth, an unusually strong predisposition to diseases of the middle ear exists, owing, on the one hand, to the double influence of the peculiar morphological relations of the ear and the pharynx, and, on the other hand, to the diseases and conditions of life to which the child is frequently exposed." The author says further: "It must become the duty of every qualified practitioner, in a large number of general diseases, especially with children, to inform himself of the condition and powers of the ear, and also to direct the attention of the attendants to this organ without waiting for urgent symptoms to proclaim themselves. In all violent inflammations of the nasal and pharyngeal mucous membranes, the frequency of a simultaneous disease of the mucosa of the ear should be borne in mind; especially in scarlet fever and small-pox, in diphtheria and croup, the ear should never be forgotten, as experience shows both that these affections very frequently extend to this organ, and also that the aural inflammations accompanying them often assume an unusually serious and destructive character."

The responsibility thus urged, and by so eminent an authority, is well worthy of consideration, and a means of preparation for meeting it is had in the careful study of such works as that which is the subject of this notice.

For the special student this book fills a gap left by the majority of the text-books, and with its foot-notes and the bibliographical list which precedes each chapter furnishes a means of ready reference.

For the faithful reproduction of the original which marks this translation the translator merits the thanks both of the profession and the author.

The Illustrated Quarterly of Medicine and Surgery has completed its first year in a manner creditable alike to editors and publishers. Its illustrations are far more effective than words alone can possibly be. It is a new departure in medical journalism, and we trust will meet the encouragement its merits deserve.

— The *Medical Record* on two different pages of the same issue puts the number of physicians in the United States at 65,000, and at 83,000. Even at the former figure we have, according to the estimate of the Medical Academy of Paris, considerably more than one third of all the doctors in the world. Many hands make light work.

Medical and Surgical Journal.

THURSDAY, JANUARY 18, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

DR. ROBERT KOCH'S LATEST ESTIMATE OF PASTEUR'S METHODS AND DISCOVERIES, AND OF THE PRESENT POSITION OF THE GENERAL INOCULATION PROBLEM.

THE day appointed for the first general meeting of the last International Congress of Hygiene at Geneva was looked forward to as the great occasion of the Congress. M. Pasteur was announced as prepared not only to expound his previously published investigations concerning the modification and protective inoculation of disease-poisons, but to disclose new examples of modification of such poisons by the oxygen of the air, and to prove that we have really reached a general method for the modification of certain poisons, whose application has only to be varied according to the physiological characteristics of the various microbions. It was also known that Dr. Robert Koch would be present as representing the Imperial German Health Board and the German school of investigators, from which criticisms of Pasteur's work had already emanated, criticisms which Pasteur resented in the course of his remarks before the Congress.

The assembled *savants* were disappointed in their expectations. Pasteur, it is true, did present himself in the *rôle* of the "second Jenner," but he adduced nothing new in support of his previous observations, and the two new instances of inoculation with modified virus, namely, the inoculation of rabbits with culture-liquids containing microbions taken from the nasal discharge of horses dead from the so-called typhoid fever of horses, and of rabbits again with culture-liquids of microbions taken from the saliva of a child supposed to have died from hydrophobia; these instances were, for several sufficient reasons, not very satisfactory. Moreover, Koch refused to discuss Pasteur's statements or to support his previous criticisms on the legitimate ground that as each expressed himself but very imperfectly in the other's language, science could derive little benefit from such a debate. He promised, however, to put in print with as little delay as possible whatever he had to say on the subjects of Pasteur's communication, and Pasteur, recognizing the propriety of Koch's course, promised that his reply to such a publication should not be long in appearing. With this the scientific quidnuncs of the Congress were forced to content themselves; but if they lost a sensation it seems as if scientific medicine will make a more important gain.

Koch's arraignment — for it is hardly less — of Pasteur has been published, and is now in our hands. It is a very able and interesting paper, and we give as brief an abstract as possible of the principal points taken up by the writer. Koch thinks Pasteur goes much too fast and too far in proclaiming the discovery and development of a general method of protective inoculation against infectious disease, and denounces the two latest examples cited by Pasteur in favor of such a position not merely as absolutely valueless in that respect, but as admirably exhibiting Pasteur's false methods of investigation, and the way in which they inevitably lead to false conclusions. Koch states the point of view from which he himself regards the investigation of infectious diseases thus: It is not yet proved that all infectious diseases are caused by parasitic micro-organisms, and proof must therefore be found in each separate case of the parasitic nature of a disease. The careful examination of all parts of the body affected by the disease for the presence of parasites, a knowledge of their relative frequency in the affected organs, and of their relation to the tissues, constitutes the first step toward such proof, and all the aids which the microscopical technique of the present day offer are to be brought to bear upon such an examination. Only then can one expect to prove that such micro-organisms are of a pathological nature, and that they are the specific cause of the disease in question. For this purpose they must be propagated in unmixed cultures, and when in this manner they have been freed from all adherent substances of the affected body they are then to be inoculated, if possible, upon the same species of animal as that originally attacked, or at least upon such animals as are well known by unmistakable symptoms to be subject to the disease in question. Such was the procedure pursued by Fehleisen in regard to erysipelas, and such that of Koch himself in isolating his bacillus of tuberculosis. Koch next states how far he believes Pasteur's methods depart from the rules here laid down, and how both the methods and results are unreliable on account of the absence of proper microscopical research, on account of the inoculation of mixed substances, and on account of the selection of unsuitable animals for the experiments. Pasteur not being a physician, Koch thinks it less justifiable to reproach him with his mistaken interpretation of pathological processes and symptoms of disease.

All these sources and kinds of error Koch finds exhibited in Pasteur's reports of his experiments in inoculating rabbits with the nasal secretion of horses dying from so-called typhoid fever and with the saliva of a child dying from hydrophobia. The rabbits died in both cases, Koch thinks, and supports his opinion pretty strongly, not from typhoid fever or from rabies, but from the well-known septicæmia to which they are especially prone, the symptoms and the microbion of which had been previously thoroughly studied and described by Davaine and others. Moreover, the so-called typhoid fever of horses has nothing in common with the typhoid of men, but belongs, according to Schütz, to the group of erysipelatous processes. No characteristic microbion was found in horses to begin

with, the substances for inoculation were not taken from characteristic organs, the materials used for inoculation were not unmixed, the malady from which the rabbits died did not even present any of the general symptoms of typhoid, and rabbits were not the proper animals for the test. Almost the same remarks are applicable to the inoculation of the other rabbits with the saliva from the hydrophobic child, and in regard to this Sternberg has shown how full even the saliva of a healthy person is of various microbions.

In regard to the claim of Pasteur for the discovery and enunciation of a general law for the modification of their poisons and for the protective inoculation of infectious diseases, Koch considers that splenic fever is the only infectious disease which can as yet be properly accepted in favor of such a claim; that even in this one disease the results are thus far limited to sheep, and both the strength of the virus to be used for the first and second inoculations and the length and degree of protection secured are still very uncertain, much more uncertain than Pasteur has acknowledged; that the danger of the inoculation itself for the subject and for other animals and men is increased in direct proportion to the efficacy of the virus employed. As another objection to Pasteur's claim that he has discovered a general law, Koch recalls the fact that it was Toussaint of the Veterinary School at Alfort who first inoculated the modified virus of splenic fever, the virus being modified by the addition of a one per cent. carbolic solution, or by raising the temperature to 55° C. (150° F.); that although Pasteur's method for modifying the virus is much better than Toussaint's, his interpretation of the process by which the modification is brought about is incorrect, for it is not, as his own experiments show, the direct action of oxygen which produces the modification, but the presence of products evolved by the microbions themselves, — an evolution favored by oxygen, by elevation of temperature, and replaced by the presence of carbolic compounds.

In regard to Pasteur's "chicken-cholera," Koch believes no practical use of the modified virus has been made by poultrymen, and thinks that the existence of a specific pathological microbion of such a disease has yet to be demonstrated.

Koch thinks that the general principle of preventive inoculation with artificially modified virus should not be triumphantly proclaimed as established until we have succeeded in modifying and transforming into protective inoculation-material bacteria belonging to diseases of men, of which he thinks we know the bacilli of tuberculosis, of leprosy, of typhoid fever, the micrococci of erysipelas, and the spirochaete of relapsing fever. In none of these diseases, it will be remarked, is one attack protective against a second. Koch acknowledges the modification of the bacillus of splenic fever as an established fact and as a very important step in the right direction, and desires to give Pasteur proper credit for his contributions toward this result, but thinks Pasteur should not make a secret of his processes, and should have more regard for truth and scientific accuracy in his statements, and that all future workers in this department should proceed with greater "objectiveness," and with a more conscientious self-criticism.

Pasteur's reply to this brochure of Koch's will be awaited with much interest and some impatience.

GOVERNOR BUTLER'S LUNACY COMMISSIONER.

The facts that the nine original members of the State Board of Health, Lunacy, and Charity, undertook their multifarious duties with an earnest desire to make the work of the Board as successful as possible; that six gentlemen have resigned their positions, thoroughly satisfied that the several functions cannot be properly attended to by a single unpaid commission, and that at least three highly accomplished men have refused appointments on the Board, believing it to be a mistake, are sufficient to satisfy most people that Governor Butler is not entirely wrong in his criticisms, and that ex-Governor Talbot is not wholly right in his defense of his Board.

It may be that the management of the charities of the State has in general improved, although there is room for much better things in the out-door poor department. It is quite generally acknowledged that the health department has been crippled, and, until the recent appointment of Dr. Walcott, there was for some time no member of the Board who had special training in sanitary science. The committee on lunacy, however, is the weakest part of the combination, as it does not contain a single person who has any real knowledge of insanity and its treatment, and, unlike the health department, has never had a paid executive officer in its employ who possessed such information in the matter of lunacy as to entitle his opinions to respectful consideration in doubtful or difficult cases. In the management of the hospitals, therefore, and in intelligent criticism of the work of the various boards of trustees and medical staffs, as well as in shaping the policy of the State in the treatment of the insane, the Board is of very little use, except in so far as it reviews financial administration. It is fair to say, also, that it does no special harm, and that its treatment of the insane asylums of the State has been marked by a conservative and careful policy. It has done much good in satisfying a certain limited popular clamor for supervision of the insane on the part of the State, although there are already signs in the National Association for the Protection of the Insane and the Prevention of Insanity that the tub thrown to the whale has not proved wholly satisfying. At the same time the Board now in existence has adopted a fair course towards the hospitals, and has, in the four years of its existence, gained an amount of experience, which is likely to prevent it from taking any unwise or unconsidered steps, or from interfering where it is not likely to do good; and we should be very sorry to see an untrained lunacy commission or commissioner going over the same ground again and learning from the beginning even the amount of knowledge

on the subject which is possessed by the Board of Health, Lunacy, and Charity. The experiment, too, might not fully please "the gallery."

The fact is none the less true that we need very much an expert lunacy commission, composed of at least three persons: one lawyer, one physician skilled in the knowledge of insanity and the treatment of the insane, and one gentleman acquainted with financial matters. After the experience of England, France, Scotland, Ireland, and Canada, a single commissioner is not to be thought of for such responsible duties. But in considering this question we must estimate political probabilities, we regret to say, and they are more uncertain than the weather. It is doubtful whether a sufficiently accomplished medical man can be found to take any place which is likely to be offered to him, and, unless such a man can be found, it is folly to attempt any change. In the mean time, we must get on without the much-desired intelligent criticisms of our insane asylums, the classification and treatment of the insane must go ahead in a scrappy, unsatisfactory way, the commitment of persons to asylums is to be attended with many evils that should be remedied, and the whole question of insanity must wait for that broad discussion and able handling for which we shall, in spite of many difficulties, continue to hope.

SIR JAMES PAGET ON SOME RARE AND NEW DISEASES.

THE first "Bradshawe" lecture was delivered in December last by Sir James Paget before the Royal College of Surgeons of England. It is a notable production, not only as the first of a series established on a liberal foundation, and destined undoubtedly to contribute much to medical science, but as presenting in itself a broad and striking view of what may be called the philosophy of medicine. The title selected by the illustrious speaker was "Some Rare and New Diseases," but any of his hearers who expected merely a description of two or three maladies not heretofore laid down in the books must have been amazed at the breadth of the field covered, and the intellectual power displayed under this modest and unassuming title.

A distinction is first drawn by the author between a rare case and a rare disease, the former being usually a common disease which merely presents one or more unusual features. This class is passed by, and attention is directed to rare diseases, and more especially to those which were lately new and have become more frequent; to those, in fact, which represent variations and combinations of morbid conditions obtained from hereditary transmission. He also leaves out of consideration those diseases which are new merely to knowledge, not in fact; citing, however, parenthetically, the typhoid intestinal ulcers preserved unwittingly by John Hunter, as illustrative of the importance of preserving pathological specimens, however we may fail to appreciate their significance, in hopes that future generations may read their interpretation. But apart from these there are certain affections not hard to be discerned, but so well marked, so distressing, and both during life and after death so large and distinct in all their characters, that it seems impossible that unless they were very much rarer formerly than they are now they could have been overlooked. As illustrative examples he cites the joint disease discovered by Charcot in connection with locomotor ataxia, and Paget's own "osteitis deformans." Moreover, he believes that instances of typical gout have become comparatively rare, and that a large number of less acute diseases, to be regarded as forms of incomplete or suppressed gout, are more frequent; such, for instance, as phlebitis of the femoral and external iliac veins.

Sir James Paget makes an *a priori* argument that such changes of type are to be expected, basing it on the ground that the child does not inherit an exact likeness of either parent, nor an exact composite of both; that while it is difficult to maintain the pure "breed" in any of the domesticated species of animals it is not likely that disease should be transmitted with more fixed conformity to type than are normal compositions. "Hybrids and mongrels must be even more common among diseases than among species and varieties." And, finally, that instances of *reversion* to an antecedent type after an interval of one or more generations are as reasonable in the abnormal as in the normal characteristics.

Some of our chronic cases may be, for instance, gout crossed with scrofula, or syphilis mingled with scrofula, rheumatism, or gout. In the author's own words: "It is best to believe that we rarely have to do with a simple and unmixed morbid constitution. There are few worse habits in practice than that of commonly saying of our case 'it is all gout,' and of another it is all scrofula, or all syphilis. We might as well say of any Englishman that he is all Norman, or all Anglo-Saxon, or all Celt. We may, indeed, sometimes see persons who appear to be as types of races unchanged in many centuries, but in practice we had better study every man as, for better for worse, a composite of many ancestors."

A corollary of great practical importance is deducible from these considerations. And that is with regard to the uncertainty of medicines. We are all disappointed frequently in the action of drugs to which accumulated experience has ascribed a value. Bromide of potassium, useful as it often is in epilepsy, not infrequently fails. Arsenic sometimes does and sometimes does not do good in lymphadenoma. Yet the author suggests that "that which some call the fallacy of therapeutics is often the fallacy of diagnosis." *Analytic diagnosis*, with reference to the component elements of each case, is what is needed. Only in proportion as this is attained can therapeutics become a satisfactory science.

Space forbids our noticing many of the other valuable suggestions of this lecture. It closes with a strong plea for the maintenance and use of pathological museums, and has an especial word to say in behalf of the preservation and study of the "bad specimens," which are usually undervalued. The "good,"

that is, typical, specimens have their place in the instruction of beginners; but it is the incomplete, mixed, and transitional examples from which most will be learned of the essential nature of disease. Attention has been confined too strictly to species; varieties are equally deserving of study.

MEDICAL NOTES.

— Chicago during the past year has had fifty-four homicides, but only one capital sentence. Governor Stephens, of Georgia, has, according to the daily papers, since his accession to office released from imprisonment twelve convicted murderers, and commuted the sentence of two others from death to imprisonment.

— The Medical Purveyor of the United States Army at St. Louis makes the startling statement that the accumulations of worthless medicines disposed of from time to time by the government are bought up by dealers and resold again to the trade in outlying towns.

— On November 1, 1881, the Illinois State Board of Health issued a certificate to practice medicine to Heinrich Andreas Lüders on the strength of a diploma from the University of Göttingen in 1866 and letters purporting to be from reputable practitioners. It has since been learned that the true Lüders, after graduating at Göttingen, returned to his native place, Riffenbrück, in the Duchy of Brunswick, where he practiced medicine until his death in November, 1878. The proper name of the individual who personated Lüders in Illinois was Lambrecht; he has previously been a barber. How he obtained the diploma is unknown. He is charged with various instances of malpractice. This is the thirty-first case of an individual falsely swearing to be a graduate of a foreign university detected through the Illinois "Act to Regulate the Practice of Medicine."

— A case of ruptured membrana tympani is reported from Vienna, caused by an ardent lover kissing his inamorata in the ear.

— During the year 1882 there were twenty-nine suicides in Boston, twenty-three being of men.

— A correspondent of the *American Register* spoke in a recent communication of the *Specula* discovered in Pompeii, and now in the wonderful museum at Naples. In a subsequent communication he speaks of the discovery of a more elaborate one in the new excavations. It is what the Italian surgeons describe as a "speculum quadrivalve." The others, already existing in the museum, are respectively "bivalve" and "trivalve." This last, the "quadrivalve," is exquisitely proportioned, and the whole movement is unsurpassed by the most perfected modern surgical instruments. Dr. Jacobelli, of Naples, has made a study of this latest "speculum" discovery, and is to publish an illustrated article on it in the medical journal, the *Morgagni*.

— General Hazen, Chief Signal Officer, has written a long letter to the New York *Tribune*, in which he shows the absurdity of attempting to predict storms a long time in advance, as in the case of the recent prediction by a Canadian named Wiggins, that there would be a terrific storm in March. He closes by saying: "Such statements fill lunatic asylums, and those who make them are enemies of society. Their publication is a pestilence, and it is the duty of all persons who know and prize the truth to denounce them, and enlighten those who might believe them."

— The French medical profession has been having "*un incident*" in connection with the delivery of an address at the opening of the term of the School of Medicine at Nantes. The gentleman deputed by his colleagues to deliver this address took for his topic the work of Claude Bernard, with whom the speaker had lived on intimate terms. In the address he took occasion to speak depreciatingly of contemporary science, and to make some references of a personal and religious bearing which jarred on the feelings of his hearers. Laennec wrote a friendly letter urging him to modify some of the passages and insisting on the withdrawal of others, but the orator refused, claiming his right to say what he thought best. The Faculty appealed to the Minister of Public Instruction, who sustained their objections to the oration on the ground that the orator did not speak in a personal capacity, but as a representative of the body that had selected him, and was therefore bound to respect the sentiments of that body.

NEW YORK.

— The New Jersey City Charity Hospital was formally opened January 4th. It is a plain frame building, one hundred and twenty-five by twenty-eight feet, with two wings, each twelve by eighteen feet. On the first floor is the male ward, which is divided by sliding doors into two apartments, each forty by twenty-eight feet. The reception and operating rooms are on either side of the main entrance, and at the opposite end of the ward are the nurses' quarters and dining rooms for such patients as are able to go to their meals. On the second floor are the female wards, and here the arrangements are essentially the same. There is an elevator to convey patients to this floor, and a balcony, upon which the female wards open, extends all along the west side of the building. The cost of constructing the hospital, which is at present arranged for eighty beds, but has room for a hundred, was $12,000, while $30,000 was paid for the land occupied by it.

— On December 30th and 31st the annual collections for the hospitals of the city were made under the auspices of the Hospital Saturday and Sunday Association, contributions being made in all the churches and synagogues, through the treasurers of trade auxiliaries, through collection boxes placed in drug stores and places of public resort, and by means of other agencies. It is supposed that the amount collected is larger than in any previous year.

— On Thursday, January 4th, the ladies of St. Elizabeth's Guild visited Blackwell's Island, and distributed fruits, jellies, and other delicacies among the sick in Charity Hospital and in the almshouse.

— Dr. Henry B. Sands has been appointed con-

sulting surgeon to the Emigrant's Hospital on Ward's Island in place of Dr. John M. Carnochan.

PHILADELPHIA.

— The following officers for the ensuing year of the College of Physicians were elected at the stated meeting in January: Dr. Alfred Stillé, President; Dr. J. M. Da Costa, Vice-President; Dr. Richard A. Cleemann, Secretary; Charles S. Wurts, Treasurer; I. Hewson Bache, Curator of Museum; James H. Hutchinson, Honorary Librarian; J. Ewing Mears, Recorder; Publication Committee, Drs. J. M. Da Costa, James H. Hutchinson, and Roberts Bartholow; Committee on Directory for Nurses, Drs. W. W. Keen, S. Weir Mitchell, and Albert H. Smith; Library Committee, Drs. L. Lewis, Walter F. Atlee, I. Minis Hays, S. W. Gross, and Morris Longstreth.

— The American Association for the Protection of the Insane, etc., will meet in this city on the 25th inst., the sessions being held at the College of Physicians.

— A. J. Drexel has contributed $5000 to the University of Pennsylvania for the endowment of a free bed in the new wing for chronic diseases, erected as an adjunct to the University Hospital by Henry C. Gibson. The bed will be known by the name of the donor. This makes the fifteenth free bed endowed in the new structure. The new wing will accommodate about one hundred patients, and the full endowment required for its maintenance will not be less than $400,000.

— A new clinic hall of the Woman's Hospital was opened with appropriate ceremonies on the 4th inst. Addresses were made by Bishop Simpson, Prof. Rachel D. Bodley, Dean of the Faculty, Mrs. Rachel C. Bunting, Treasurer of the Board of Managers, Dr. Benjamin B. Wilson, Dr. Anita E. Tyng, and others. The new hall is of brick, two stories in height, with high steps and an ornamental front. It stands on North College Avenue, between the hospital and the college, and faces Girard College on the south. The interior is finished in modern style, and in hard woods throughout. A large amount of room is devoted to an amphitheatre and two stairways. The lecture-room is well lighted by a large skylight and windows on the north side of the building.

— A polyclinic and post-graduate school will be opened shortly in Philadelphia, application having been made for a charter to the present session of the legislature. The following branches will be taught by prominent specialists: Orthopædic and general surgery, by Dr. T. G. Morton; operative and clinical surgery, Dr. Richard J. Levis; diseases of the throat, Dr. J. Solis-Cohen; diseases of the chest, Dr. J. C. Wilson; diseases of the eye, Dr. William Thomson; surgical anatomy, Dr. John B. Roberts; diseases of the ear, Dr. C. H. Burnett; pathology, Dr. Morris Longstreth; nervous diseases, Dr. Charles K. Mills; chemistry, Dr. Henry Leffmann; diseases of the skin, Dr. A. Van Harlingen; diseases of women and children, Dr. E. L. Duer. The Philadelphia Polyclinic and College for Graduates in Medicine, as it will be called, has not yet settled upon its location, but it will be in the centre of the city, probably not far from the Pennsylvania Hospital, permission having been accorded by the managers of this institution to utilize its clinical advantages for the benefit of the prospective classes. The success of this new college is assured by the character of those who are interested in it; they each individually have a well-earned reputation for ability, activity, and application, and for the most part are experienced clinical teachers.

Correspondence.

THE NEW LENOX MALARIA CASE.

MR. EDITOR, — In the report of the "New Lenox Malaria Case," in the JOURNAL of the 28th ult., I find that the testimony of Dr. S. D. Brooks, called in rebuttal by the State, is given somewhat fully, as contradicting my evidence as to the prevalence of malarial disease in the neighborhood of the Water Shop Pond in Springfield. As the evidence of Dr. Brooks was given at a stage of the trial when it could not be replied to either by me or by other witnesses, I think it due to myself to ask you to print the following statement from some of the leading physicians of Springfield.

Respectfully, WM. G. BRECK, M. D.

From personal observation and information from other sources, we have not learned of the existence of malarial disease within half or three quarters of a mile from "Water Shop Pond" in this city during its late prevalence.

Miscellany.

FEMALE EDUCATION IN RELATION TO ITS MENTAL AND PHYSICAL RESULTS.

DR. T. S. CLOUSTON, whose reputation in Great Britain as one of the experienced authorities upon mental and nervous diseases is well established, recently delivered two lectures upon the above subject before the Edinburgh Philosophical Institution, a brief report of the first of which we append. An abstract of the second lecture will be given in the next issue. Dr. Clouston's views are not new, and for this very reason a certain class in our communities may refuse to read them, but they are forcibly expressed, and derive weight from Dr. Clouston's authority.

There were a good many reasons, the lecturer said, why physicians and physiologists should have opinions about the education of youth rather different from those held by the professional educators; and he proceeded to show that the former viewed the human being as a unit, with the body and mind inseparable, and that the practical aims of modern medicine, founded on this enlarged study of man, were getting more to

be concentrated on measures for the prevention of diseases, rather than on measures merely for their cure after they had arisen. Now, to prevent disease one must control the conditions of life, especially in youth, when the human being is most amenable to influence for good and evil that affect the whole future life. The process and the method of education most undoubtedly influenced health very strongly. Vital energy, which was available for many purposes, should not be appropriated for one; and if in a girl they applied to education the energy which ought to go towards growth, and towards the strengthening of the body, they would produce a small and unhealthy specimen of humanity. At the different periods of life nature used her energy in different ways. In babyhood it was chiefly in body growth; in girlhood, partly growth and partly brain development; while in adolescence nature's effort was to obtain a full development of the various functions. The period of adolescence was not one of production, but of acquisition, and they had to see that it was acquisition all around, and not in one single direction only. If the original constitution derived from ancestry has been good, if the conditions in childhood have been favorable, if education has been right, and the development of the whole being in all her faculties equal and harmonious after nature's plan, then they must have a woman in perfect health, which meant happiness, with the full capacity for work, for resisting evil influences, and for living her allotted time. In pointing out that one might use up by undue pressure at one time of life the power that ought to have been spread over a much longer period, he remarked that the physician must look at the human being from the cradle to the grave, and not one portion only, as, unfortunately, the educationist must necessarily do, having nothing to do with life after the period of education was over. He (Dr. Clouston) would have the educator's reputation partly to depend, not on what he turned out at eighteen, but on the result at forty, fifty, or sixty. If it had helped life to be healthy, successful, happy, and long, then education had been good; if unnecessary disease, unhappiness, unhealth at any period of life had been the result, then it had been bad. One generation, he submitted, might by living at high pressure exhaust its share of energies, and might thus draw a bill on posterity without transmitting to the next generation enough to pay it. He believed many of them were now having the benefit of the calm, unexciting, lazy lives of our forefathers of last generation. Proceeding to speak of some of the bad results which he thought were caused by the present system of the education of young women, he referred to the physical and mental changes which accompanied the transformation from girlhood to womanhood, and strongly urged the importance of the whole brain and the whole body coming to maturity, pointing out that the developing process stopped at adolescence. Whatever was done then, or left undone, was final. Who in his senses, he asked, would deny that it was far better for nineteen women out of twenty to begin life healthy than well educated? Alluding to the danger of developing hereditary nervous diseases, he asked why should they spoil a good mother by making her an ordinary grammarian? It had been said that most great men had had mothers with strong minds, but he believed that few of them had highly educated mothers. There was usually an innate force and good development of mind and body in the mothers of such men, and they had usually led quiet, uneventful, and unexciting lives. One great argument for higher education was that it made woman a fitter companion for highly-educated men; but he held this view to be erroneous; and, in conclusion, illustrated his contention by pointing to the ideal pictures of young women drawn by Tennyson, Shakespeare, George Eliot, and Thackeray.

EUCALYPTUS TREES AT ROME.

A WRITER in the *Journal of Forestry* speaks in some detail of the experiment of planting eucalyptus trees by the Italian government. The discovery of its anti-malarial influence was made about fourteen years ago, when a few Trappist monks — mostly French — established themselves at Trois Fontaines, about one and a half (English) miles outside the Porta di S. Paolo, at Rome. The spot was highly malarious, and the monks were at first compelled to return to the city at night to sleep. In 1870 they made the experiment of sowing seeds of eucalyptus. The seed was dear, the fathers were poor, and had no knowledge of the management required. But the plants came up, and were set out around the building, and by the time the surviving seedlings had attained their fifth year the site was sufficiently improved in its sanitary conditions to enable the monks to sleep in the building unharmed. Previously, although they absented themselves at night, the malaria had carried off twelve of their small community. These results having been pressed on the notice of the Italian government, to whom the mortality among the railway employees in the Campagna has been for some time a matter of grave concern, an arrangement was concluded, about three years ago, for the establishment of an experimental farm at Trois Fontaines, under the management of the Trappists, for the reclamation and sanitation of certain adjacent lands with the aid of convict labor. The results of the experiment appear to have been most satisfactory. The success attending the planting of the young eucalyptus trees is in marked contrast with the failures in other parts of the Campagna and in private gardens within the city. The agreement with the government stipulated that 12,500 eucalypti shall be planted annually, and this number was exceeded in 1880 and 1881. Most of the trees are doing well, and there appears to be no question as to the fact of their anti-malarial influence, whatever may be the true proximate cause. The country round about Trois Fontaines is flat, with low undulations. The soil is pozzuolana, interstratified with clay, and here and there capped with patches of basalt or with a hard, stony crust, called *cappelaccio*, which is shattered into small fragments with dynamite and dug in. Water is found at depths of eighteen inches to three feet. The eucalyptus makes large demands on the soil, and no data exist as to the amount of spacing requisite to ensure successful planting. The plan has therefore been adopted of allowing nine hundred trees to the hectare, or about three hundred and sixty to the acre, which appears to answer well. The seedlings are planted out in two-feet trenches, disposed in lines. The seed is sown in light, open frames, in soil of the kind in which the trees are eventually to grow. When two to four inches high the seedlings are set out at distances of four inches apart each way, in small boxes holding forty plants each. In these they are

housed under glass during the winter. This protection is not indispensable except in unusually severe weather, but the plants are better for being spared. They are set out in trenches when the frosts are over. A remarkable fact is the immense amount of water which these trees absorb from the ground. It is noted that maize and other cereals grow well when planted between the trenches of eucalyptus, whereas the soil previously gave no good results to this or any other crop.

AUTOGENESIS OF CYSTICERCI.

A CASE was recently reported before the Société Médicale des Hôpitaux of Paris[1] of a man having fifteen or twenty cysticerci (of which one, excised for purposes of diagnosis, revealed the characteristic hooklets of the parasite). The peculiarity of the case consisted in the fact that the individual had passed links of tapeworm about a month previous to the appearance of the first cyst, and two months after this had gotten rid of the whole of a tænia solium. The reporter of the case believed that the person had become affected with the cysts from his own tænia without the reception of the ova in another animal, which is ordinarily supposed to be necessary to the complete cycle of development. Authorities are cited to show that antiperistalsis, vomiting, etc., may convey the proglottides of the parasite from the intestine into the stomach, and as the action of gastric juice is alone necessary for the liberation of the ova, the individual thus may ingest accidentally the ova expelled by himself. That the complemental portion of the cycle may occur without the intervention of the swine or any other animal is demonstrated by an enthusiastic student of helminthology, who swallowed four cysts taken from a human cadaver, and in three months and two days first noticed the appearance of proglottides in his stools, which were demonstrated later to belong to the tænia solium.

INTESTINAL OBSTRUCTION; MANUAL EXPLORATION OF ASCENDING COLON.

A CASE in which very active treatment for stoppage of the bowels was applied not only without injury to the patient but with apparently favorable effects on the abnormal condition, is described in the *Practitioner* by Dr. Hunter, of Peru. The patient was a muleteer, and was suffering from the usual symptoms of intestinal stoppage, with hiccough, vomiting, and great tympanites. Pretty active medicinal treatment having been given with no good effect, and only temporary relief to the tympanites having been afforded by puncture of the intestine, manual dilatation of the stricture was resorted to after this manner: —

When the patient was well under the influence of chloroform he was placed on his left side, the nates drawn to the side of the bed, and the knees bent. The tube and catheter were introduced into the rectum, but without result. When the hand (length eight inches) had been fairly introduced, it was found to be comparatively free in a vaulted cavity without any apparent exit. Upon careful examination a slight projection was felt, something like a soft but not prominent os uteri, with a central depression. Into this central depression first one finger and then another were insinuated until all the fingers were introduced in a conical form. Slowly dilating and advancing, the hand found itself free in a large roomy cavity, and in contact with a soft pultaceous substance; no hard lumps of any kind were felt. From the tip of the middle finger to the point where the arm was grasped by the anus measured sixteen inches. The long tube was now passed along the front of the arm and hollow of the hand: immediately there began to escape a dark-green semi-fluid and flatus. The hand being withdrawn, the fluid continued escaping but slowly, until warm water was injected by the tube. The effect of this was most satisfactory — more and more of the always dark-green fluid and gas escaping, partly by the tube, and partly by the side of the tube. Considering the excessive tympanites that had existed it was astonishing to see the very large amount of this dark-green fluid which was ejected. No scybala were expelled. The patient, as he was recovering from the chloroform, made voluntary expulsive efforts, increasing the amount ejected. The abdomen being now soft and flat, and the patient expressing himself as feeling better, the tube was withdrawn. The patient never complained of any pain following this operation, — only of a little soreness about the anus, — and in a fortnight was well.

As a suggestive contrast to this case, we may mention from the *Revue de Chirurgie* an article by M. Quénu detailing six cases of spontaneous rupture of the rectum, most of them in cases of old prolapse and usually accompanying an effort, as defecation, vomiting, and once the patient's straining during surgical reduction of a prolapse.

The symptoms are of course very severe, as the accident is usually accompanied by protrusion of the intestine, forming a large mass between the thighs which quickly becomes congested. To elucidate the pathogeny of this accident, M. Quénu has made experiments to ascertain the resistance which the rectum offers to a bursting force. Having stitched up the anus, he pumped air into the rectum, measuring the pressure. He found that the rectum would bear, without giving way, a pressure equal to that of a column of mercury sixty centimetres high (about twenty-three inches). When the pressure passed that of seventy centimetres, the peritoneal coat began to crack, and the other coats followed. We may add, that Schatz has shown that the ordinary pressure within the rectum is equal to that of a column of mercury from twenty-five to thirty centimetres high, and that it sometimes rises to that of fifty centimetres of mercury.

TREATMENT OF PUERPERAL MASTITIS BY IODIDE OF LEAD OINTMENT.

IN the *American Journal of Obstetrics*, Dr. Thos. T. Gaunt expresses his disappointment at the ill success of belladonna in checking the secretion of milk, but reports good effects from iodide of lead. He says: —

"The breast being thoroughly dried and perfectly cleansed, we smear its surface with the officinal ointment of the iodide of lead, and then gently rub it in until a considerable quantity is absorbed. Soak a piece of sheet-lint, of a size sufficient to cover the breast, in the following solution: Acetate of lead, from ℥ij to ℥ss to the pint, of a one-to-four solution of alcohol.

[1] L'Union Médicale, December 12, 1882.

If we desire a more elegant preparation, eau de cologne may be substituted. If there be much pain it is often well to apply an ice-bladder upon the sheet-lint covering the breast. The lint should be frequently dipped in the lead lotion. The following phenomena will present themselves: First, a cessation of pain, fullness and uneasy feeling of distention, which is so annoying. It is common for the patient, who has been exhausted by pain and consequent loss of sleep, to fall into a refreshing slumber even after the application is made. In the course of three or four hours the breasts may be completely emptied by an experienced hand. The ointment should be used as a lubricant during the manipulation. By applying the iodide freely twice or thrice, daily, the secretion will be gone in less than one week, as a rule. The pivotal point in the treatment is the use of this ointment; the evaporating lotion and cold being only adjuncts. I have proved by repeated trials that, when applied alone, it is capable of exerting an absolute control over the secretion. I believe we here invoke a specific action from the lead iodide. A point of considerable moment is the partial anæsthesia it is capable of inducing, which thus enables us to empty the glands, where before even slight pressure was badly borne. Its action without doubt extends to the epithelial cells and inhibits their secretory activity, as is seen in its action, in cases like the above, in causing the drying up of the secretion."

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 6, 1883.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2820 (no report from St. Louis): under five years of age 970: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 602, consumption 386, lung diseases 379, diphtheria and croup 221, small-pox 98, scarlet fever 90, typhoid fever 50, diarrhœal diseases 32, cerebro-spinal meningitis 27, measles 23, whooping-cough 21, malarial fevers 17, erysipelas 13, puerperal fever 10. From *typhoid fever*, Pittsburg 10, Philadelphia seven, Cincinnati six, New York, Chicago, and Providence four each, Baltimore three, Boston, Buffalo, Charleston, and Fall River two each, Milwaukee, Springfield, Somerville, and Malden one each. From *diarrhœal diseases*, New York and New Orleans seven each, Chicago six, Brooklyn four, Buffalo and Fall River two each, Baltimore, Pittsburg, Providence, and Nashville one each. From *cerebro-spinal meningitis*, New York nine, Chicago six, Buffalo three, Philadelphia and New Orleans two each, Brooklyn, Boston, Pittsburg, Milwaukee, and Fall River one each. From *measles*, New York 16, Philadelphia two, Chicago, Boston, Baltimore, Worcester, and Lynn one each. From *whooping-cough*, New York eight, Pittsburgh three, Cincinnati two, Philadelphia, Brooklyn, Chicago, Boston, Baltimore, Milwaukee, and Nashville one each. From *malarial fevers*, New York six, Brooklyn and New Orleans five each, Cincinnati one. From *erysipelas*, New York and Buffalo three each, Milwaukee two, Philadelphia, Brooklyn, Chicago, Cincinnati, and Charleston one each. From *puerperal fever*, Chicago six, New York, Boston, New Orleans, and Buffalo one each.

Five cases of small-pox were reported in Cincinnati, Pitts-

burg two; diphtheria 57, scarlet fever 33, typhoid fever 11, in Boston; scarlet fever 18, and diphtheria three in Milwaukee.

In 35 cities and towns of Massachusetts, with a population of 1,008,240 (population of the State 1,783,086), the total death-vate for the week was 19.84 against 23.36 and 20.75, for the prerious two weeks.

In the 28 English towns, with an estimated population of 8,469,571, for the week ending December 23d, the death-rate was 27.6. Deaths reported 4480: acute diseases of the respiratory organs (London) 633, measles 110, whooping-cough 106, scarlet fever 100, fever 85, diarrhœa 47, diphtheria 24, small-pox (London three, Newcastle two, Wolverhampton one) six. The death-rates ranged from Derby 20 to Liverpool 40.1; Brighton 21.9; Birmingham 23.1; Nottingham 24; Birkenhead 25.3; Sheffield 27.5; Sunderland 28.5; Leeds 30.7; Newcastle-on-Tyne 32.9; Huddersfield 36.9.

For the week ending December 16th, in 170 German cities and towns, with an estimated population of 8,457,136, the death-rate was 24.2. Deaths reported 3934: under five years of age 1745; consumption 529, acute diseases of the respiratory organs 467, diphtheria and croup 184, scarlet fever 84, measles and rötheln 65, typhoid fever 52, whooping-cough 48, small-pox (Mannheim and Prenzlau two each) four. The death-rates ranged from 34.7 in Posen to 11.1 in Wiesbaden; Königsberg 28; Breslau 26.7; Munich 29.7; Dresden 26.8; Berlin 25.7; Leipzig 21.3; Hamburg 26.7; Cologne 19.8; Frankfort a. M. 16; Strasburg 22.2.

For the week ending December 23d, in the Swiss towns, population 494,390, there were 31 deaths from lung diseases, consumption 24, diphtheria and croup 10, diarrhœal diseases eight, erysipelas one, typhoid fever one. The death-rates were, at Geneva 24.7; Zurich 16.2; Basle 18.7; Berne 19.5.

The meteorological record for the week ending January 6th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date. December, 1882. January, 1883.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

RESOLUTIONS OF THE HARVARD UNIVERSITY MEDICAL SCHOOL ON THE RESIGNATIONS OF PROFESSORS HOLMES AND BIGELOW.

At the meeting of the Medical Faculty, on the 6th inst., the following record was made: —

Resolved, That the resignation of Professor Oliver Wendell Holmes is received by this Faculty with no ordinary feelings of regret; not only on account of the loss of a gifted teacher who for more than a generation has so faithfully and brilliantly filled the chair of anatomy, but because of the severing of those close personal relations in which as colleagues we have been so long and so pleasantly associated.

Resolved, That we recognize the great loss which this Faculty has sustained in the retirement from the chair of surgery of Professor Henry J. Bigelow, whose keen observation, accurate research, and rare genius in devising new and important methods of operative procedure have done so much to render this School conspicuous, and to make American surgery illustrious throughout the world.

INTERNATIONAL MEDICAL CONGRESS.

COPENHAGEN, *December*, 1882.

SIR, — According to the desire expressed by the International Medical Congress at its seventh session, in London, 1881, and in consequence of later discussions on this subject, it has been resolved that the eighth session of the Congress shall be held in Copenhagen.

Especially in order to prevent collisions with other medical congresses we beg to request that you will, even now, in your esteemed journal draw attention to the fact that the eighth session of the International Medical Congress will take place in Copenhagen during the days from the 10th to the 16th of August, 1884.

We are, sir, your faithful servants,

P. L. PANUM, C. LANGE, *Secretary-General.*

President of the Organizing Committee of the Congress.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 5, 1883, TO JANUARY 12, 1883.

SKINNER, JOHN O., captain and assistant surgeon. Granted leave of absence for one month. Paragraph 2, S. O. 5, A. G. O., January 6, 1883.

WOOD, MARSHALL W., captain and assistant surgeon. Granted leave of absence for one month. Paragraph 3, S. O. 4, Department of the East, January 8, 1883.

JOHNSON, R. W., first lieutenant and assistant surgeon. Granted leave of absence for one month. Paragraph 2, S. O. 4, Department of Dakota, January 5, 1883.

MUNDAY, BENJAMIN, first lieutenant and assistant surgeon. Assigned to duty at Fort Klamath, Oregon. Paragraph 3, S. O. 195, Department of the Columbia, December 29, 1882.

MIDDLESEX NORTH DISTRICT MEDICAL SOCIETY. — The quarterly meeting of the Middlesex North District Medical Society will be held at the St. Charles Hotel in Lowell, Wednesday, the 31st inst., at four o'clock P. M. A paper prepared by Dr. William H. Lathrop, of Tewksbury, on Incipient Mental Disease, will be read by the author. A paper on Venesection in the Treatment of Disease will be read by its author, Dr. Harvey Knight, of Lowell. GEORGE C. OSGOOD, *Secretary.*

BOOKS AND PAMPHLETS RECEIVED. — Legal Medicine. Vol. II. By Charles Meymott Tidy, M. B., F. C. S., late Deputy Medical Officer of Health and Public Analyst for the City of London. New York: William Wood & Co. 1882. Wood's Library of Standard Medical Authors.

A CASE OF PARALYTIC DISLOCATION OF THE HIP-JOINT, AND OTHER CASES OF INFANTILE PARALYSIS, WITH REMARKS ON THE SURGICAL TREATMENT OF INFANTILE PARALYSIS.[1]

BY E. H. BRADFORD, M. D.

Case I. M., a girl eighteen months old, referred to me by Dr. Emerson, of Concord, presented the following unusual deformity: The right thigh was flexed and abducted so that it was at right angles with the trunk; though movable at the hip-joint it could not be adducted or brought in a line parallel with the other. The limb was cold to the touch, and there was little or no power of active motion of the thigh, except through the action of the glutei muscles; the child, however, could move its foot slightly. On passive motion the limb could be moved freely outward, but could not be adducted, or but slightly. The adductors of the thigh were flaccid. The glutei muscles, and the tensor vaginæ femoris, were not paralyzed. In the groin, on the ramus of the pubes, half way between the symphysis pubis and the anterior superior spine, a rounded mass was to be felt, which on rotating the thigh was found to be the head of the femur moving in a false socket, to be felt on the ramus. It played in this false acetabulum with some freedom, and could not be displaced by ordinary force.

According to the mother's story this was first noticed at the time the child was three months old, no cause being assigned. The patient was, of course, unable to stand, but was able to hitch about on its buttocks, using its arms as a propelling power. The left leg below the knee was less firm to the touch than is normal.

The child was etherized, and, with the assistance of Dr. T. Dwight, the head of the femur dislocated from its articulation, and the limb brought into a position parallel with the other. Some force was required to effect the luxation. No remains of a true acetabulum could be found, and the limb was therefore placed in as nearly a normal position as could be determined. In order to secure the thigh in the corrected position a plaster-of-Paris bandage was applied around the whole limb and the pelvis. This was worn eight weeks, after which a steel appliance was used designed to prevent the limb from being flexed and abducted; after two weeks the child was removed home.

At the present time, two years later, the patient's condition is as follows: The limbs are parallel and of equal length; the trochanter on the right (the affected) side is in the proper position relatively to the Nélaton line; the head of the femur is in its normal place, and the limb can be rotated freely, adducted, abducted, and flexed. The child is able to flex the thigh, using the glutei and the tensor vaginæ femoris; but the adductors and rectus are absolutely powerless and flaccid; the child can move the foot well and extend the leg from the knee feebly. The tibiales on the left foot are weak, and the foot is in a position of slight valgus. The right thigh is somewhat atrophied, but the limbs are of equal length. When the apparatus is applied the child can walk about the house. When out-of-doors it needs the help of the parent's hand or a stick as a security against falling, but without the apparatus is unable to stand.[2]

Case II. H., a boy five years old, presented himself for treatment, 1877, with the following history: A year before, the child had a slight attack of sore throat, which did not confine him to bed. The boy on the second day fell while standing, his right knee giving way under him. He was obliged to use a crutch, and never regained power in his limb.

His condition, on examination, was as follows: There was complete paralysis of the extensors of the thigh and leg. The knee was contracted, the foot was in the position of an equinus. On the application of apparatus the limb became gradually straighter and the equinus position was partially corrected. The boy became able to walk without crutches and to play ball, run, climb fences, etc. Without the apparatus the limb is entirely helpless. Five years later the condition remained the same, but the left limb is two inches shorter than the other.

Case III. F., a girl five years old, presented herself in 1877 for treatment, with the following history: Four years before the child was sick for two months with "brain fever" and "inflammation of the bowels," and was found after this to have lost all her "strength," and could neither sit nor stand up, or move her hands or legs; three months later she began to use her arms. She was seen by many physicians, and was treated at the Massachusetts General Hospital by Dr. J. J. Putnam, with marked benefit. She was afterwards under the care of an irregular practitioner using a "vacuum cure," and was subsequently treated by many empirics.

Her condition was as follows: The patient could sit upright with difficulty. The arms were strong and they and the trunk were well developed, with the exception of the muscles of the back, which seemed smaller than normal. The legs appeared to be of normal length, but were much atrophied. There was marked contraction of the ham-string tendons of the left leg and of both tendines Achillis. The right foot was in the position of equino varus, and the left of simple valgus. The child leaning its body upon a chair was able to bear a slight amount of weight upon the right limb, but the left doubled up under any weight. There was no power of motion in the left limb except at the hip-joint, and no power over the right foot, and but little of the right knee. The patient could move about only by pushing herself on the floor with her arms and hands. There had been no improvement in the past two years, and all that the parents hoped for was that she might be able to stand at some time with the help of crutches.

Appliances were used, made in such a way that the knee of the left limb could not bend forward, and so that the feet were kept from turning inwards or outwards.

After six months the girl was able to stand, with crutches, when the appliances were used, and in a year to stand without the help of crutches. If the appliances were removed the child was helpless as before. In the course of time the patient improved a great deal in general strength, particularly in the muscles of the back. At the present time, five years after she came under my observation, her condition is as follows:

[1] Read before the Surgical Section of the Suffolk District Med Society, October 22, 1882.

[2] Reclus (Des Luxations Paralytiques du Femur, Revue Mensuelle de Med. and Chir., 1878) describes somewhat similar cases of dorsal dislocation.

Wearing the apparatus, she is able to walk about the house without the aid of a cane or crutch. When out-of-doors she uses a cane; and with this she is able to walk a mile. The patient can stand on the right limb when no apparatus is applied, but still needs a foot support to correct the tendency to talipes equino varus. The left limb is entirely useless without an apparatus, and the child helpless. Both legs have grown in length, but not in circumference to any noticeable degree.

CASE IV. M. A. C., a girl six years old, was seized, September, 1877, with a febrile attack accompanied by pain and stiffness in the lower limbs, with loss of power ending in paralysis of motion of both legs. For a time enemata were necessary to move her bowels, and a catheter was used to empty her bladder. A year later the child presented herself for treatment in a condition of perfect general health, but with absolute uselessness of her lower extremities. She was unable to stand even with crutches, and dragged herself about upon the floor. On examination her limbs were found cold and atrophied, but without loss of sensation. There was pronounced equino valgus of the left foot, and equino varus of the right. The muscles on the anterior surface of the left thigh and leg, and of the anterior surface of the right thigh, were paralyzed. The legs were contracted at the knees to a slight degree. The deformities of the feet and knees were corrected by the use of apparatus, and after wearing appliances designed to prevent the knees from dropping forward, the girl became able to walk, first with the help of crutches, afterwards without them. In the course of time the right limb developed so that no artificial support was necessary except for the foot, and the patient became able to stand upon that limb without help; she could also walk with crutches when not wearing her appliances, but no weight could be borne upon the left limb unless supported. This is her condition at present (1882). There is, however, a tendency of the feet to relapse to a degree to the condition of valgus and varus. In the hope that tenotomy might correct this tendency, in 1880 the tendines Achillis were divided, but the tendency to relapse remains the same unless corrected by the constant use of appliances.

CASE V. W., a girl eleven years old, a companion case to the above, differing in that the paralysis had persisted longer (ten years), and that at the hamstring tendons were contracted, right-angled contraction at both knees being the chief deformities. The girl crawled about upon her hands and knees. The contractions were overcome without tenotomy, and the child became able to walk with crutches and an apparatus, and to a limited extent without crutches. Three years later the patient died of typhoid fever. She had outgrown her apparatus, having been removed from observation during that time, and recontraction at the knees had taken place, so that at the time of death her limbs were as much deformed as before.

CASE VI. G., girl, four years old, with paralysis of the extensors of the left thigh and leg and of the right leg, contraction of the left knee, an equino varus of the left, and equino valgus of the right, foot. The paralysis had appeared when the child was one year old, and the resulting deformity had been corrected by apparatus, but on the neglect of apparatus relapse had occurred.

The correction of the contracted knee in this case was readily effected by bandaging the limb to a straight posterior support. The contraction in one foot was corrected by tenotomy, and the other in comparison by gradual stretching, and the child furnished with apparatus enabling her to walk, which she learned to do without other support than that furnished by the appliance.

CASE VII. M., girl, fifteen years old, referred to me by the kindness of Dr. Douglas Graham. Two years before the patient, without known cause, was attacked suddenly with paralysis of both lower extremities. But little improvement followed, and finally her limbs became contracted at the knee-joint. Massage was employed by Dr. Graham, and some improvement followed. Right-angled contraction, however, at both knees remained, and equinus of both feet. The object of treatment was, if possible, to so far straighten the limbs that the patient should be able to stand with the help of crutches.

In this case paralysis of both quadriceps extensor muscles was present, the flexors of both feet, and the adductors of the thigh; the glutei muscles and the lower spinal muscles were also atrophied.

As the patient was a nervously organized girl, it was decided to attempt to correct the deformity without tenotomy, and under appliances for that purpose the contractions were overcome in four weeks.

The tendines Achillis were contracted and stretched after the contraction at the knees had been overcome. At the present time (six months later) there has been no gain in the power of locomotion, the limbs have remained straight, and the patient, using apparatus and crutches, can stand if leaning against the wall, but cannot walk, being unable to balance herself even with crutches, owing to the weakness of the glutei.

CASE VIII. R., healthy boy, fifteen years old, was paralyzed when a child; recovered to a certain extent, leaving him with a partial paralysis of the quadriceps extensor muscle of the right limb, which was two inches shorter than the left. There is a paralytic talipes calcaneus of the right foot, and slight varus of the left. The patient in walking places his hand upon the right thigh to prevent its dropping forward. No contractions were present.

An apparatus was applied which prevented the knee from dropping forward, and enabled the patient to walk much more readily. With this on, it is not necessary for him to hold his knee with his hand. Wearing the apparatus the patient has walked ten miles, but without it he cannot without fatigue go farther than half a mile.

It will be seen from the above cases that contractions can be overcome readily and limbs made straight, and that sometimes by means of appliances the patients are able to walk without crutches and sometimes they are able to walk with crutches, which before was impossible. In certain cases appliances are of no use and sometimes of slight use.

The amount of benefit obtained by treatment is not, however, to be measured simply by the correction of the deformity or increase in the power of the limb. Children condemned to a life of paralysis and distortion, with the floor as their only playground, dragging themselves about by their arms, dependent for a change from room to room upon the assistance of an attendant, practically life prisoners to a corner of the chamber, with a wheel-chair as the limit of freedom, are among the most pitiable objects the physician meets.

An almost incalculable boon is conferred if we are merely able to put them in a position to move about with crutches. This can be done in a large number of these cases, as can be seen by the foregoing histories.

The natural history of this disease has been well sketched in a recent lecture by Charcot,[1] which deserves quotation: "The attack is sudden, frequently without prodromata; usually, especially in children, a slight fever (sometimes of several days' duration) precedes the paralysis. Pain during the first few days may be present, but this is not an essential part of the disease, and indicates a diffusion of the medullary irritation. . . . This occurs more frequently in adults. The paralysis attains its greatest intensity in a few hours, and rarely progresses beyond the first day. There is a lowering of the temperature and a violet tinge in the paralyzed limb. The paralysis generally retrogrades, but usually certain muscles or certain fibres of certain muscles remain disabled. The large cells (in the anterior cornua) are the points primarily attacked, but the inflammation may extend to the neuroglia and the vicinity, and foci of red softening may develop in infantile paralysis, but not in progressive muscular atrophy. The faradic irritability ceases in all the paralyzed muscles in a few days after the attack, but the galvanic excitability lost in the muscles destined to be permanently destroyed will increase in muscles which regain their power, and subsequently the faradic irritability will reappear."

Sensation is not affected, and although atrophy is always present and the growth of the limb is diminished by the paralysis and the circulation is enfeebled, as manifested by a coldness of the extremities, there appears to be no diminution in the power of repair in the non-paralyzed muscles of limbs, for recovery after tenotomy is as speedy as in a normal limb. Atrophy does not affect the fatty tissue, and the limb may, in patients inclined to flesh, be round and plump, although cold and flabby to the touch.

The gain in power after the original attack begins usually in about two weeks, and continues in a period of from six months to a year, after which no gain in the paralyzed muscles can be expected, although the non-paralyzed muscles enfeebled by disease may become stronger, increasing the usefulness of the affected limb. Sometimes complete recovery after extensive paralysis takes place.[2] The improvement is sometimes gradual to a wearisome degree, as is illustrated by the following: —

Case IX. A. D., a healthy boy, was, when two years old, attacked with complete paralysis of all the extremities, with the exception that the fingers and toes could be moved. The onset was sudden, with, as a prodroma, slight feverishness for a day or two. Pain lasted for a few days. No improvement followed for three weeks, when the left arm gained somewhat. After six months there was no improvement. His condition a year later was that of complete loss of motion in the right arm and both legs, complete loss of power in the muscles of the back and abdomen, so that if an attempt were made to make the patient sit up the thorax would fall forward on to the abdomen, as in a cadaver. The patient could not support the weight of the head, but could move the head when recumbent. Some motion of the fingers of the right hand and slight motion of the toes remained. There were slight contractions of the gastrocnemii. The child's general condition was good.[3]

Case X. It has been said that bed-sores never occur, but in one patient, a child three years old, with paralysis of both lower extremities, having the clinical history and characteristics of infantile paralysis, a large slough formed from pressure over the coccyx. The slough extended until the bones of the coccyx suppurated away. Death subsequently followed from exhaustion. The surroundings of the child were such that cleanliness could not be attended to, and he remained in one position during the whole day.

The muscles of the lower extremity are more frequently affected with a permanent paralysis than those of the upper; and all the muscles of the lower extremity may be involved, but this rarely occurs at the same time, although one such case was seen by Duchenne. The anterior muscles are those usually destroyed (that is, the extensor communis, the tibiales, and the peronei). The gastrocnemius, however, is sometimes paralyzed. Permanent paralysis of both arms has never been seen except in one case. If the upper extremity is affected the deltoid muscle rarely escapes. The muscles of the foot proper commonly retain their power.

The fact that the anterior groups of muscles are the ones which suffer the most has suggested the theory that the destruction is in part due to the constant strain on the muscles when in a weakened condition. Gravity places the paralyzed limb most frequently in a position with the foot dropping downwards and the knees bent. The posterior muscles are thus in a measure protected from stretching, and hence may be regarded as more likely to escape local degenerative changes. The fact that the deltoid of the muscles of the arm is usually involved would support the theory, but paralysis of the gastrocnemius offers an exception, one, however, which is not common, and perhaps induced by accidental causes. Unproved as the theory is it would appear to deserve more consideration in the treatment of the early stage than it usually receives.

In treating this affection, besides whatever methods may be considered as capable of favoring a subsidence of the central irritation or promoting a gain of muscular power, attention should be paid to the prevention and correction of deformities, and in case of permanent paralysis to appliances which will aid locomotion, and in that way prevent farther degeneration from disuse of non-paralyzed muscles.

In regard to the prevention of deformities it seems probable that a great deal more can be done than is usually attempted. Facts as observed seem to justify the opinion that contractions are not an essential feature of the paralysis, but the result of the position of the injured limb.[4]

It should be an axiom of treatment, even in the earlier stages, that a palsied limb should never be allowed to assume the positions of the usual contraction for any length of time, and, if necessary to prevent this, appliances devised for the purpose can be worn.

In the correction of already existing deformities only those of the knee and foot demand attention here, contractions of the arm being rare, and it being impossible to gain much in the hand by any mechanical treatment.

[1] Gaz. des Hop., June 17, 1882, page 555.

[2] For cases of this sort see Meyer's Medical Electricity, American translation. An instance of complete recovery was also related to me by Dr. Chase, of Dedham.

[3] The child a year later died of pneumonia without having improved noticeably in the mean time.

[4] C. F. Taylor, Infantile Paralysis. Volkmann, Klinische Vortrage, No. I., 1.

The choice between strictly operative and non-operative methods is one to be guided more by the circumstances of the case than by any fixed rule. Any one who has had any experience with tenotomy will testify to the safety and the great ease with which deformities are corrected with the aid of tenotomy, and if it were left to a surgeon, aided by good nursing, to decide which method he would prefer, considering his own trouble, he would undoubtedly choose tenotomy, as the annoyance of fitting and watching an apparatus would be in this way avoided. There seems to be no reason to doubt of the repair after tenotomy in these cases. This has certainly been true in all the cases where I have performed tenotomy. This correction of the limb can be immediate, the limb being fixed by plaster of Paris or any mode of absolute fixation; or if that procedure is deemed hazardous, correction may be made to take place more gradually, at the expense, however, of greater trouble to the surgeon.

Tenotomy, however, is in the eyes of the public an operation, and as such is dreaded, disturbs the household, and is to be avoided if possible on that account. In by far the greater part of these cases an equally good result can be obtained by stretching as by dividing the muscles. The contracted muscle can be stretched by an appliance devised to correct the deformity gradually; or in certain cases the muscles relax under the employment of an appliance which checks motion in the direction of contraction but allows motion in the desired direction and enables the patient to stand, enlisting the aid of gravity to extend rather than shorten the muscle.

The choice of apparatus will vary according to the habit and experience of the surgeon; from the plaster of Paris, frequently reapplied, to a more or less complicated apparatus.

Beside correction of the deformity, it is desirable to promote locomotion. Morton, in Philadelphia, to accomplish this, doubled up his patients' atrophied legs without attempting to correct deformity, using them as if they were stumps after a thigh amputation, and placed them in artificial legs. Albert, of Vienna, in cases of paralysis of the quadriceps extensor muscles excised the knee-joints with a result of an anchylosis, enabling the patient to walk on a firm support, it not being possible for the knee to drop forward. In by far the greater number of these cases some power remains in the muscles at the hip-joint; or if that is not the case patients learn to swing at the hips in walking, their trunks remaining erect on the pelvis by action of the back muscles. If the patient with a palsied leg attempts to stand the limb gives way, the knee drops forward (never backward or sideways). If this is prevented the patient can of course stand as well as if the knee were anchylosed.

Apparatus, therefore, should be so devised that the knee cannot drop forward, and for its employment at best advantage there should be no contraction at the knee. As the apparatus is to be worn habitually it is better that it should be hinged at the knee with a catch that can be locked or unlocked.

It is important that the heel be brought fairly to the ground, as otherwise the limb is not placed well under the patient. Lateral deviations (varus, valgus, and calcaneus) do not prevent walking, but of course need correction for other reasons. Of the methods for this correction, which belong to the category of the treatment of club-foot, little will be said here, except that tenotomy is by no means essential, though the treatment is hurried by tenotomy, and not endangered by it.

It need hardly be added, although the fact must always be borne in mind, that the deformity is necessarily liable to relapse. As the paralyzed muscles cannot recover, the primary cause of the deformity must always be present, and will need constant attention. The patients may be considered to be in the condition of persons with artificial limbs, which must never be allowed to become out of repair.

The following facts in regard to infantile paralysis, (essential paralysis of children, myelitis of the anterior cornua,) should be borne in mind in treatment: —

(1.) Recovery complete or partial is the rule after the initial attack.

(2.) After the maximum of recovery has taken place the deformity becomes an important element in the affection.

(3.) Deformities should be prevented if possible and corrected when present.

(4.) The promotion of locomotion by suitable appliances is, in the late stage of the affection, the only means of treatment.

The application of proper appliances is a matter of simplicity in principle, requiring a great deal of attention in detail; as unless such apparatus exactly meet the indications demanded, full benefit cannot be obtained.

The surgeon should himself be familiar both with the principles and the detail of treatment, as he is otherwise unable to judge of the thoroughness of his methods.

NOTES ON A CASE OF ACUTE CHOREA IN AN ADULT, ASSOCIATED WITH PROFOUND MENTAL DISTURBANCE.[1]

BY H. R. STEDMAN, M. D.,
First Assistant Physician, Danvers Lunatic Hospital.

IN this case, which came under my observation at the West Riding Asylum, the absence of many accompaniments usually considered characteristic of chorea, as well as the prominence of the mental phenomena, seem to render it sufficiently instructive to merit some analysis.

W. W., a married man, twenty-three years of age, was admitted to the asylum February 18, 1882. The medical certificate which accompanied his papers of admission represented the patient to be a violent lunatic, the facts indicating his insanity being as follows, namely, (1.) Those observed by the certifying physician: "Talking incoherently, takes no notice of any questions put to him." (2.) Facts communicated by others: "Will sit for hours together without speaking." The patient's family physician stated: "He was by nature eccentric in his habits, and inclined to be self-willed. Just before the attack he became depressed in spirits, irritable in temper, and suspicious of those about him. During the attack he was sometimes violent, sometimes depressed, but had lucid intervals, raved indifferently on various subjects, and would strike with great violence indiscriminately." Chloral, bromide of potash, and belladonna, had been given, with no good effect.

When brought to the asylum the patient was securely bound by a straight-jacket, reënforced by heavy

[1] Read before the Boston Medico-Psychological Society.

leather straps. These had been applied by those intrusted with his removal. As soon as he was freed rom restraint he was seen to be suffering from severe chorea.

The patient was placed in a padded room after being bathed, and became much quieter.

Various members of his family were agreed on the following points in his history: As a child and youth he had been active, intelligent, fairly robust, and not emotional. He had never suffered from convulsions, rheumatism, or in short any illness other than the present, with the exception of "pleurisy, with inflammation of the lungs," several years before. There have been no deaths in the family, and few illnesses. The patient's domestic circumstances had been satisfactory. Just before and ever since his marriage, six months ago, he had worked very hard at his trade, carving and gilding. About four weeks before his admission he was obliged to leave his work on account of severe, continuous, and general cephalalgia, which persisted, and confined him to bed for two weeks. At this time noticeable alteration in his manner and conduct became for the first time evident. He was dull, preoccupied, and reticent, appearing dazed and indifferent to his condition and surroundings. He again went to work and seemed "like himself" in every way. A week later he returned home in a confused state of mind and soon became "delirious." For the next two days he was much excited, refusing to go to bed or to take food, threatening to throw himself out of the window, and crying at trifles. No hallucinations or delusions appear to have been expressed. Just after the excitement became pronounced he began to wriggle about in bed, fling his arms about, contort the face, protrude the tongue, etc. This disturbance subsided in a day or two. He then conversed freely and said that he had fallen in attempting to board a tram-car just before this attack came on, but did not meet with any injury; that he then became confused, and wandered about the town a long time before he could find his home. Three days before admission, when supposed to be rapidly convalescing, his former condition returned with renewed intensity, being ushered in by rapid and disconnected talk. From this time he became very unmanageable, and his movements were so energetic that he was with difficulty prevented from falling out of bed, and his knuckles and elbows were abraded from contact with the wall. He showed no disposition to violence.

Physical Appearance. — Pupils dilated, the right excessively so and only slightly responsive to light. All his voluntary muscles are affected with chorea. He incessantly writhes and plunges about the bed, tosses the arms, clinches the fists, contorts the face, etc. There are abrasions on elbows and knuckles. The skin over the sacrum is reddened, and on the tongue is an ulcer the size of a sixpence, caused by biting. The lungs appear to be in a healthy condition. The heart sounds are apparently normal. Pulse 140, and of fair strength. No swelling or redness of the joints. Appetite fair. He passes his urine and fæces in bed.

Mental Condition. — Though questioned in an interval of comparative calmness the patient can, evidently, make nothing of what is said to him. He is ignorant of where he is, how long he has been here, why he is here, etc. He makes incoherent, nonsensical replies to the simplest questions, but protrudes his tongue when asked. Expression lost and wondering. During sleep there have been slight movements of the upper extremities and head occasionally. He is to be given chloral hyd., twenty grains, morning and night, and the spine is to be sprayed with ether twice daily.

February 23d to 26th. On the whole there has been distinct improvement. The choreic movements are now absent during sleep. By day he is occasionally quite still, and although there is, at present, much movement of the head and facial muscles, he has been quite free from spasm. A small eschar has formed over the sacrum, and the abrasions of the elbows and hands are inflamed. He is fed by the attendant with soft food, but has great difficulty in masticating it properly. He is still irrational and incoherent. He talks in a whisper as if conversing with some one, and most disconnectedly. Says that he is in "Fletcher's Mills."

March 4th. He is not still a minute, although the movements are now confined to the face and upper extremities. He talks in a low tone most of the time. Occasionally he jerks out a sensible reply, after evidently trying to collect his thoughts, but soon wanders off onto a variety of subjects.

March 8th. He is quieter, but still scowls and rolls about somewhat. Touching any part seems to excite muscular contraction. He is still unable to concentrate his thoughts or to keep them in the right channel, just as he fails to direct his muscular movements properly after making a good beginning. He can tell the time and answer simple questions when roused and made to apply his mind. Still passes his evacuations in bed. Bed sore deep. A slough has separated from it under poulticing, etc., Chloral hyd. discontinued and tonic treatment substituted.

March 11th to 19th. There is but little mental improvement, although he has been generally quite free from morbid movements. He often starts up and looks about him, muttering disconnectedly. In answer to a simple question he replies, "They were laughing at me, — either jump over here or over there." Allows the medicine to drool from his mouth without attempting to swallow. Gives an occasional rational answer after much pressing. He is still unclean in his habits.

March 26th. The patient has been for some time entirely free from choreic movements. He now sits up most of the day. He has to-day, for the first time since admission, used the vessel voluntarily, and has walked about. His whole expression is brighter. He answers simple questions correctly, but not readily. He still stares wonderingly when addressed, and makes strenuous but vain attempts to understand and reply.

April 6th. His improvement has steadily progressed since last report, cleanliness being one of its earliest symptoms. The patient has now, in a great measure, recovered his intelligence. He knows where he is, and that he has been much deranged. His memory is nearly restored. He is still confused and wandering in his manner, and his ideas are not perfectly coherent. Expression rather perplexed and vacant. Elevation of the eyebrows and frowning is unduly frequent. He remains pale and thin. He eats and sleeps well. Gait fairly steady. Bed sore entirely healed.

Three weeks later the patient was discharged recovered.

Examinations of the heart made from time to time during the progress of the case, as well as the exploration of the fundi, gave negative results.

There was some elevation of temperature during the

hree weeks following his admission, it being 101.3° F. on February 27th, and during the remainder of the time only rising to 100.5° F. in four instances. The pulse remained rapid for about the same length of time. The patient showed no discomfort from the bed sore, and but little from the application of the faradic current.

Before considering the mental complication, which is the principal feature of this case, there are other particulars which deserve notice, even at the risk of some repetition. First, the absence of any mental defect or nervous troubles in the patient or any of the family, as well as the absence of a previous attack. Second, there were none of the usual exciting causes, such as alarm, mental excitement, or nervous shock, nor did repeated questioning of the relatives or examination of the patient reveal any history of rheumatism in any of its varieties, or of heart defect. These points when considered together, not to speak of the patient's age or sex, make quite an exceptional history for a case of chorea.

In regard to the disposition of such a case a word may be said here. Although many of the ordinary cases of chorea are attended at some stage by mental phenomena the motor symptoms so far predominate as to completely mask them. On the other hand, in the most severe cases the mental disturbance, which is often quite pronounced, being intensified by the energetic character of the movements, is apt to mislead the practitioner, who considers the patient simply insane, and sends him to an asylum. Whereas, if the case had been recognized at the start to be one of chorea he would hesitate to do so. The case just reported is an extreme example of this mistake and more may be found in asylum records.

We look in vain for the mention of the association of chorea with mental disturbance by many prominent writers, even slight mental enfeeblement, an almost universal symptom, being often unnoticed. It is probably considered by them as taken for granted that such a neurosis when at all severe cannot fail to produce indirectly some slight and evanescent mental manifestation at least. With others, however, the preponderance of evidence is in favor of the presence of mental disturbance in varying degrees of intensity in most cases of chorea. Ziemssen believes that psychical disturbances are rarely absent, although in the lighter cases they are but little developed, and consist only of irritability and changeability of temper. Dr. Arndt, a competent German observer, does not believe in the existence of chorea without more or less simultaneous affection of the intellectual faculties.

The consideration of these combined manifestations may best be approached by grouping our facts and conclusions according to the different periods of life, as the disease will be seen to present, in this respect, distinctive features. The liability to mental symptoms also will be found to be governed by the age.

(1.) *Childhood.* — The well-known and commonest form of chorea, characterized by twitchings of various sets of muscles, and more or less unsteadiness, occurs at this period. It is apt to be of long duration, is light in intensity, and not distinctly localized. Although the trouble gives considerable discomfort, mental symptoms are rarely evident enough to attract notice, but are likely to develop when the disease is prolonged. The memory becomes impaired, and there is great difficulty in concentrating the thoughts. This tendency of nervous impressions, to be expressed almost entirely by convulsive movements in early childhood, may be explained by the undeveloped condition of the higher centres, mental disturbances only preponderating with advancing years and consequent cerebral growth.[1] An extreme example of the influence of long continued chorea in lighting up mental trouble in a child predisposed to nervous disease is reported by Putzel. The patient, aged eight years, during and after a season of repeated attacks of chorea, began to show groundless aversion toward his parents, and finally exhibited delusions of sight and hearing, together with violent suicidal and destructive tendencies.

(2.) *Puberty and Early Adult Life.* — At this period (between the ages of thirteen and about twenty-three) the severe, dangerous, and fatal cases have been found to occur, and the mental phenomena to be most marked and peculiar. Our case is a remarkable example of this class both as to severity and mental complication. A comparatively small number of such cases has been recorded, and a few are here cited to show the variety of ways in which the mental symptoms may be manifested, as well as the conditions which influence them. Dr. Barker reported in the *Lancet*, many years ago, a case of chorea associated with hysteria, followed by temporary dementia. The features of interest were the presence of hysterical attacks — a frequent occurrence during chorea in young women — and also the appearance of mental failure succeeding to the cessation of the choreic symptoms. The dementia was manifested by incoherence, indifference to surroundings, fatuous expression, etc. Sturges reports a similar case in a boy of thirteen years, who had had a previous attack. The chorea was of a chronic form, and accompanied by hysterical seizures. After many variations he fell into a half fatuous state where it was extremely difficult to estimate the precise mental condition. Both of these observers, however, are inclined to ascribe the entire mental condition in these cases to the hysterical element.

Of two cases reported by Putzel under the head of maniacal chorea, one occurred in a girl of seventeen, with no hereditary neuropathic tendencies, after sudden arrest of the menstrual discharge. In this case the mental aberration, which was manifested by delusions of persecution and identity, as well as by great violence and destructiveness, was most marked at the height of the affection, and disappeared soon after the subsidence of the other symptoms.

An unusual variety of insanity, termed "rheumatic," which occurs in the course of acute rheumatism, has also been called "choreic" on account of the frequent and singular combination of mental and bodily symptoms. Clouston [2] reports two striking cases, and refers to similar ones reported by Griesinger and Fleming. Wigglesworth [3] contributes two cases with corresponding symptoms. Such attacks are described by Clouston as follows: "A patient laboring under acute or subacute rheumatism ceases to complain of the pain in

[1] Maudsley has given the name "choreic" insanity to a kind of delirium peculiar to children, which is characterized by marked incoherence of an automatic type, but *accompanied by none of the motor symptoms of chorea.* When used in this sense the term "choreic" insanity is misleading, as one might reasonably infer from it the presence, to some extent, of the bodily pathognomonic symptoms of chorea, whereas we find in their place as a basis for such a classification only a fancied similarity between mental and motor incoördination in a few cases of insanity in children.

[2] Journal of Mental Science, July, 1870.

[3] Ibid., July, 1872.

the joints, and simultaneously shows signs of mental excitement of a peculiar delirious type, insomnia, intense excitement, violent, ungrounded fears, utter disregard of danger, etc. . . . Accompanying these symptoms, beginning along with them, varying in their intensity as they vary, and passing off as they disappear, is a series of violent choreic movements. The features are contorted, the head jerks from side to side, the limbs are thrown about, and the body is raised up and down. Along with the choreic movements hallucinations of the senses show themselves." Thus we have maniacal chorea occurring as a symptomatic form of acute rheumatism at this period of life.

Returning to W.'s case we are struck by the persistence of the mental symptoms for a considerable period after the cessation of the chorea, no less than by the antecedent and accompanying derangement. This is all the more remarkable when we call to mind that the acute dementia which occasionally follows a rapid succession of severe *epileptic* fits lasts but a short time even when the patient has been greatly prostrated by the convulsions. It is not sufficient, therefore, to explain such a condition of things by referring it to the irritation of the choreic movements or the anæmia or bodily weakness of our patient, more especially as the mental disturbance not only followed but preceded and accompanied the convulsive movements. Moreover, in the light of analogy and recorded observations something more is necessary to account for such an exceptional occurrence than the obvious supposition that the delicate nerve mechanism would be long in regaining its function. Our knowledge of the pathologico-anatomical changes and the way in which they act on the central nervous system is so meagre that the causes in such a case as this can only be surmised. Nevertheless it is reasonable to assign the associated phenomena to some common cause, the nature of which has yet to be determined, and to consider the psychical and choreic changes independent of each other.

(3.) *Middle Life.* — The rare, incurable cases of this period are frequently found to be associated with some form of chronic mental disorder, and examples of this class may be found in most asylums. The spasmodic twitchings and phenomena of incoördination occurring at this time are generally localized, and not severe, giving, in fact, little inconvenience. They are apt to appear late in the disease, and are subject to remissions. In this period also, and in that of old age, there is a symptomatic type, if we can so designate, as does Ziemssen, those cases which are based upon anatomical lesions of the brain and cord.[1]

(4.) *Old Age.* — Besides the special class mentioned in the preceding division there are many cases in which the chorea of old age is accompanied by mental disorder, which can properly be referred to any gross organic lesion. Professor Charcot in his recent work on senile chorea has, we are told, no pathological anatomy for it. He regards it as merely an emotional disease, and quotes examples to show its origin in distressing events and violent passions, as well as the mental enfeeblement that goes along with it. Between this form of the disease and that occurring in middle life there is no decided difference, except that it is a more common occurrence, if its frequency among the aged insane in asylums is any criterion. Moreover, it has been thought by some to be in many cases a potent *cause* of mental imbecility in old people by its prolonged continuance, extending, as it does, over many years.

If we view as a whole the above facts and observations, we see exemplified in one and the same disease the transition from motor to mental disorder in the natural order of cerebral development. In childhood chorea is very frequent, and takes the form of light but prolonged and chiefly convulsive attacks, with only slightly impaired, because undeveloped, intelligence. At puberty and in early adult life the attacks, though less common, are the most severe as to convulsions, and are frequently attended with mental impairment, such as hysteria, dementia, and even acute mania and delirium. In middle life, the period when insanity predominates, chorea is rare, of a mild type, and when associated with insanity is insignificant in comparison with the amount of mental trouble, which is often due to some organic lesion. In old age the cerebral functions, being often scarcely less limited than in childhood, it appears not infrequently, is associated with insanity of a mild and chronic type, and though localized is persistent and not severe.

By thus classifying cases of chorea according to the character of the accompanying mental phenomena, the attempt has been made to point out the fact of a closer relationship between mental disease and chorea than is usually recognized. The results will also serve at least to swell the evidence in favor of the cerebral nature of this disorder. At the same time these observations are not to be considered as tending to overestimate the importance of a usually harmless affection. They are presented merely to bring into the foreground a peculiar aspect of chorea as a step toward a closer acquaintance with the disease in its clinical relations.

HEART PUNCTURE AND HEART SUTURE AS THERAPEUTIC PROCEDURES.[2]

BY JOHN B. ROBERTS, M. D.

It is more than probable that, in a few years, puncture of the heart wall (cardicentesis), with direct abstraction of blood by aspiration, will be recognized as the best treatment in cases of greatly dilated or much distended right heart, with intense pulmonary engorgement, and that incision of the pericardium with suture of the heart muscle will be accepted as proper in cardiac wounds. Hence these latest novelties in cardiac surgery deserve the attention of the Fellows of the College.

That punctures of the heart are comparatively harmless has been well known to many for some years. In 1872 Roger, while performing pericardicentesis on a child with pericardial effusion, thrust the needle into the right ventricle, and withdrew about six and one fourth troy ounces (two hundred grammes) of pure venous blood. The boy, who was aged five years, became pale, sweated, and had an imperceptible pulse. The withdrawal of the pericardial fluid, accomplished prior to the heart injury, was beneficial, and the cardiac puncture did no permanent mischief, for the patient recovered. Death occurred five months later

[2] Read before the Philadelphia Academy of Medicine, January 3, 1883.

from long existing dilatation and valvular disease of the heart.[1]

In Hulke's case [2] a woman with pleuro-pneumonia was supposed to have large pericardial effusion, and a trocar was introduced through the fourth left intercostal space. Nothing escaped except a drachm of venous blood, after which the patient seemed relieved of dyspnœa. She died four weeks later from a complication of diseases, and the autopsy revealed cardiac dilatation and valvular changes.

I have said elsewhere,[3] in commenting upon this case, "The abstraction of blood seemed to relieve the distended heart much better than phlebotomy would have done, as was evinced by the diminution of threatening symptoms and the decrease of the area of dullness."

Cloquet, Bouchut, Legros, and Onimus have also observed the apparent innocuousness of wounds of the heart made by capillary trocars. Steiner found, ten years or more ago, that electro-puncture needles could be quite safely introduced into either ventricle, provided they were at once withdrawn.[4]

It has been considered less safe to puncture the auricles, but the interesting paper of Dr. Benjamin F. Westbrook, just published in the *Medical Record* for December 23, 1882, seems to show that our fears are as unfounded as were those of our predecessors in regard to ventricular puncture. It is, in truth, to call attention to his case of harmless *intentional* cardicentesis, and to his researches in the surgical anatomy of the operation, that I have been led to refer to the corroborative evidence of the cases mentioned above.

I have with much satisfaction, as have many others, done venesection at the bend of the arm for the temporary relief of the distressing symptoms of dilated heart, and for the dyspnœa due to the pulmonary engorgement of acute pneumonia. If, however, a few *drachms* of blood drawn directly from the heart give the relief that could only be afforded by taking a similar number of *ounces* from the veins of the arm, it seems proper to adopt the former measure. The subsequent circulatory depression from anæmia would undoubtedly be less than after the latter operation.

It is manifestly necessary, however, to determine that cardicentesis is innocuous before it can take the place of venesection. The above-mentioned cases and Dr. Westbrook's experience tend to show that such is the fact.

Dr. Westbrook believes that the proper place to perform the operation is in the third costal interspace close to the *right* edge of the sternum. This situation enables the operator to tap the right auricle without injuring the right internal mammary vessels, and with little danger of striking the tricuspid valve. My own preference would be to perforate the ventricle of the right heart by introducing the needle through the fourth interspace, about one and a half or two inches to the *left* of the median line of the sternum. Dr. Westbrook's opinion, however, is entitled to more deference than mine, because he has studied the subject with special reference to cardicentesis, while my special investigations have been limited to the consideration of pericardicentesis.

Further experimentation in heart-puncture for the relief of cardiac distention and pulmonary engorgement is requisite, but it is probable that it will soon become a well-recognized surgical procedure in selected cases. Pericardicentesis has already taken that position, and there is no reason to believe that cardiac surgery will stop its march with the demonstration that the pericardium can be treated as the pleura.

In October, 1881, I read a paper before the Anatomical and Surgical Society of Brooklyn,[5] in which I advised resection of costal cartilage and incision of the pericardium for removal of foreign bodies in the pericardial sac, and at the same time said: "The time may possibly come when wounds of the heart itself will be treated by pericardial incision, to allow extraction of clots, and perhaps to suture the cardiac muscle."

It seems as if this time had now almost arrived, for Dr. Block has not only expressed a belief that death can be averted in many cases of heart-wounds by simple incision of the pericardium to allow escape or extraction of the clots which cause pressure and death, but has also undertaken to demonstrate by vivisectal experiments that suture of the heart is a simple operation and requires but three or four minutes.[6] He finds that opening of the right and left ventricles, and entire compression of the heart for the application of sutures, can be supported by rabbits for several minutes. During suturing he seizes the apex of the heart and draws the organ forward until the traction prevents the escape of blood from the wound. Sutures are then introduced, or the orifice closed by ligation. Even if cardiac pulsation and the respiration stop during this mechanical interference with the heart's movement, death, he asserts, does not necessarily unsue.

These experiments are even more important than the researches spoken of in regard to heart-puncture. I regret that as yet I have not been able to consult Dr. Block's original memoir, but I hope at a future time to do so, and perhaps to be able to report some investigations of my own which I desire to make in the same direction.

RECENT PROGRESS IN DISEASES OF CHILDREN.

BY T. M. ROTCH, M. D.

CRANIAL FISSURES IN INFANCY.[7]

PROF. J. WEINLECHNER, of Vienna, has published a carefully prepared paper in the *Jahrbucher für Kinderheilkunde*, presenting his investigations on the results following blows on the head during infancy, and entitled Subcutaneous Cranial Fissures, Cranial Openings with adherent Cerebrum, and False Meningocele. His deductions are made from his experience with thirteen cases, and may be summarized as follows, as already published in the *American Journal of Obstetrics:* Intra-uterine cranial fissures and fractures are extremely rare. Those occurring during delivery, and occasioned by forceps or narrow pelvic straits, are more frequent, while in a certain number of cases subcutaneous fissures are caused post partum by various traumatic causes. Here belong the falls upon the head

in rapid or "street" births, and later on blows of all sorts on the cranium. Such accidents may lead to two different forms of disease: (1.) Extension of the fissure to a cranial opening with apposition of the brain, or (2) false meningocele, the fissure here also widening. The cases show clearly that large cranial openings may develop from even slight subcutaneous fissures occurring traumatically in infancy. It is probable that most of the cases reported as congenital are really caused in this way. In twelve of the thirteen cases the trouble could be traced to trauma. Thus there were, —

(1.) Fall on head.
(2.) Fall on a footstool, and loss of consciousness.
(3.) Fall from arm to ground, followed by vomiting.
(4.) No traumatic cause could be demonstrated either by the history of the case or at the autopsy.
(5.) Found at the autopsy: several fissures with the remnants of a hæmorrhage.
(6.) Ditto.
(7.) Fall on the head.
(8.) Forceps delivery; at autopsy extensive pigmented fibrinous deposit.
(9, 10, 11.) Fall on the head.
(12.) Blow on head by a windmill.

Two different clinical conditions were found sometimes combined with one another.

A. An opening in the bone, generally irregular, in the form of a weaver's shuttle or an egg, and usually in the parietal bones. There may be extension from this to the neighboring sutures. The edges and often the whole parietal bone are bulged outward like a crater. The brain presses against the coverings of the opening, pulsates clearly, but does not project much. It cannot therefore be called cerebral hernia Seven of the thirteen cases belonged to this class.

B. There is a soft, fluctuating, sometimes transparent, tumor, which becomes smaller on pressure, pulsates more or less, but never so clearly as in the first class of cases. The edges of the opening are clearly felt only after the fluid, which has the color and chemical nature of the cerebro-spinal, is removed. The opening is only partially closed by the dura, which is closely adherent to the edges, but which has numerous openings communicating with the subdural space. The inner wall of the cyst is not formed of dura, but of connective tissue, hence it is to be considered a secondary cyst or false meningocele, having the contents of a true meningocele, but not the walls. They are larger than those of the first class of cases, sometimes reaching the size of two fists. They have a constant growth, while in the first class of cases there comes, after a time, a pause.

C. A combination of both forms. This was seen in Case 5, which is unique. The professor devotes some space to the manner in which these two forms may arise from a fissure. In both the motive power is the pressure of the cerebrum. In both the dura is probably torn, but in Class A the dura, with the, perhaps, injured brain, is pressed against the fissure, and becomes firmly adherent, and then the whole bone is arched outward, while in the B class some fluid escapes through the torn dura, and the pressure is thus partially exerted on the walls of the cyst. All the cases reported occurred at a very early period of life. The prognosis is different in the two classes. The first class reaches a point where the enlargement ceases. There is, however, always the danger of injury from without to the so slightly protected brain. The meningoceles, on the other hand, continue to grow. What size they might reach cannot be stated because in the cases reported death has occurred from meningitis following puncture. The largest tumor on record reached the size of two fists at the age of two and a half years. If they are not punctured spontaneous rupture is apt to occur. The largest fissure on record (Bardak's case) measured nine by six centimetres in the twenty-eighth year. The principal growth takes place in the early years, but even after the bones are firm the fissure may increase by resorption of the bone. This process is of course slow, but in one case amounted to an increase of two centimetres. In the first class of cases we can do nothing except to protect the brain by a well-fitting plate. Attempts at pressure exercised on the whole cranium have proved failures, and puncture is dangerous. In the second class puncture is not very dangerous even if repeated, but the sac rapidly refills. The best treatment, perhaps, is to puncture, and then, under the same precautions as in spina bifida, to inject iodine. This, however, is much more dangerous than simple puncture.

INTUSSUSCEPTION.[1]

In view of the varied opinions which exist concerning the advisability of abdominal section in cases of infantile intussusception it is well to carefully note all cases that are treated by this method, in order that a more precise knowledge of the dangerous results which may follow may be arrived at. Mr. Rickman Godlee has lately reported three cases before the Clinical Society of London.

Case I., aged nine months, was admitted into University College Hospital with well-marked symptoms of intussusception, from which it had been suffering for four days. The infant was very ill and weak, and it was doubted whether it was justifiable to perform any operation. It was not thought wise to spend much time in inflation, and accordingly abdominal section was performed without delay. Antiseptic precautions were adopted throughout, the child being protected as much as possible from the chilling influence of the spray by using as small a volume of it as possible, and wrapping up the greater part of the trunk and legs in cotton-wool. No great difficulty was experienced in finding the point of involution, nor in reducing the intussuscepted part; the wound was secured as in an ovariotomy, and a dressing of iodoform wool was applied, and secured by a flannel roller. The temperature rose the day after the operation to 105° F., but soon fell to about 100° F. It was necessary to give small quantities of brandy after the operation, and for some few days minim doses of laudanum were given to check restlessness and a slight diarrhœa, which ensued. A little suppuration occurred along the course of the sutures, but the wound healed well, and by the eleventh day it had completely closed, the infant apparently being in perfect health.

Case II. was a somewhat younger infant, who had been seized with sudden pain two days previously. The symptoms of intussusception were clear, and a sausage-shaped tumor was felt to the right of the umbilicus, easily movable, especially from above downward. In the intervals between the spasms the infant was apparently free from pain. Abdominal section was made under the influence of chloroform, and re-

[1] Medical Times and Gazette, December 16, 1882.

duction was effected by grasping the end of the ileum, and drawing it towards the wound. Next morning the infant seemed pretty well, but peritonitis set in rapidly, and death occurred the following night. The spray used in this case was remarkably small. At the autopsy the last two inches of the ileum and the first two of the cæcum were found much congested and thickened, and some slight ulceration had occurred in the ileum; the rest of the intestines were almost empty. There were marked appearances of peritonitis.

Case III. An infant aged fourteen months was admitted into the North Eastern Hospital for Children, with symptoms of intussusception that had lasted several days. The infant was very ill, and the abdomen much distended and tender. The bowel protruded at the anus. Abdominal section was performed. It was very difficult to find the joint of involution, which was seated deeply in the splenic region, and correspondingly difficult to effect the reduction. After about four inches had been drawn out the cæcum and vermiform appendix appeared, and Mr. Godlee, thinking that the reduction was complete, drew the cæcum towards the iliac fossa, and closed the wound in the abdominal wall. The infant never rallied, and died eight hours after the operation. At the autopsy it was found that seven inches of large intestine still remained unreduced. It was clear that the involution had begun, not, as is usual, at the ileo-cæcal valve, but at some point in the course of the transverse or perhaps the ascending colon; some sloughing had already occurred in the cæcum.

Mr. G. Brown related the case of a boy two years and nine months old, in which he had been unable to reduce the intussusception by manipulation after abdominal section. The attempt at the formation of an artificial anus was made as a last resource, and it was then discovered that the volvulus had become adherent, probably throughout its whole extent, to the outer layer of the intussusception, a condition which fully explained the inability to effect reduction. Vomiting set in after the operation, and death ensued in six hours.

Mr. Bryant thought that there was much analogy between the course of hernia and that of intussusception; in the early stage of each temporary measures were more likely to do good. Taxis was of value in reducing a hernia of recent date, but later it did harm, and much the same view might be held of insufflation in the treatment of intussusception.

Mr. Godlee remarked that great exhaustion was more likely to follow inflation in very young infants than in older children.

CONGENITAL INTESTINAL OBSTRUCTION.[1]

In the report of the Clinical Society for April 28, 1882, Mr. A. Pearce Gould reports the following case of congenital obstruction: A female, age three days, was brought to the Westminster Hospital, because in spite of several doses of castor oil it had not passed any meconium or fæces. It had vomited several times. The child was thin, but showed no outward deformity. The anus was normal, and the last joint of the little finger could be passed into the rectum, which seemed to be closed above. No fullness or tumor could be felt in the pelvis per rectum. A catheter and probe were each stopped about one inch from the anus. The abdomen was distended, and its walls œdematous; there was a little ascites. On the following day Mr. Gould opened the abdomen above the left Poupart's ligament. A coil of distended small intestine presented, and no coil of large intestine could be brought into the wound. So the former was carefully stitched to the edges of the incision and then opened, allowing a large quantity of meconium to escape. The child died twenty-one hours afterwards. At the autopsy no trace of peritonitis was found. The cæcum, the lower four inches of the ileum, and four inches of the colon, were filled with a firm, whitish substance, of the consistence of cheese, firmly applied to but not united with the intestinal mucous membrane. In the colon, beyond this plug, were found several masses of milk-white, firm mucus. Below this the colon and rectum were empty and firmly contracted to the size of a pipe-stem. Above it the small intestine was distended with meconium and gas. There seemed to be no fault of development but obstruction from a plug, and from the white color of the plug it was assumed that it was deposited by the third month of fœtal life, as bile appears to pass into the duodenum at the third month. Mr. Gould thought that the plug was inspissated mucus, showing that the glands of the large intestine must be acting some time before birth. Three cases of congenital obstruction referred to by Mr. Holmes, and the case of obstruction from a croupous membrane recorded in the Clinical Society's Transactions, by Dr. Skerritt, were also spoken of.

[1] Practitioner, September, 1882.

IMPERFORATE ANUS.[2]

Dr. J. K. Robertson reports the case of a male infant, in whom on examination when two days old no anal opening was found. In the anal region there was a thinning of the skin, which was a little laxer than that of the surrounding perinæum. The raphe was continued right through its centre, though it was here less marked; an incision an inch deep was made in the median line, but no intestine was found; a trocar was then plunged into the centre of the incision and meconium escaped through the canula. The infant recovered from the operation, and grew well without further trouble, the fæces finding an exit from the urethra as well as from the artificial anal opening. The child died of croup at the age of fourteen months. No autopsy.

THE ACTION OF CALOMEL ON FERMENTATION.[3]

Wassilieff's paper on this subject in the *Zeitschrift für Physiologische Chemie* is of interest from the connection which it has with the great rôle which calomel has played in the treatment of the gastro-intestinal diseases of infancy and childhood. In M. Wassilieff's experiments, calomel was added to the fluid obtained by acting on albumen with gastric juice, and to that obtained by acting on albumen with pancreatic juice; and he satisfied himself that the albumen-digesting ferment of both these fluids was not damaged by calomel, peptones in the one instance and leucin and tyrosin in the other appearing as usual; but the presence of calomel prevented the formation of secondary products such as indol and phenol. Neither hydrogen nor hydrogen sulphide formed in the fluids containing calomel, whilst they were abundantly produced in the others. In like manner the author experimented on the effects of calomel on the fat-digesting and the amylolytic ferments of the pancreas, and found that it had no

[2] Glasgow Medical Journal, November, 1882.
[3] Lancet, March 4, 1882.

modifying influence upon them, but that it arrested the changes which followed their completion, entirely preventing, for example, the butyric acid fermentation and putrefactive processes. He hence arrives at the conclusion that calomel acts differently on the formed or organized and the unformed or unorganized ferments, permitting the action of the former to proceed unchecked, but completely preventing the action of the latter.

CONGENITAL MALARIA.[1]

In the *Rev. de Méd.*, July, 1882, Dr. C. Lerouse derives the following conclusions from a careful study of this subject: (1.) It is as yet impossible to affirm the existence of a congenital form of malaria, or to establish the influence of heredity in infantile malaria. The reported cases are not numerous enough or sufficiently conclusive. (2.) The discovery of certain cases of congenital hypertrophy of the spleen in children born of malarial parents, in which the hypertrophy can be attributed to no other cause, together with the presence, in such cases, of other signs of malarial cachexia, render the existence of a congenital or hereditary form of malaria not altogether improbable. (3.) Certain children appear to be born with an inherited predisposition to malaria, and may even without being directly exposed to external malarial influences suffer from the time of their birth from an intermittent form of fever, of a type similar to that existing in the mother.

MALARIA IN CHILDREN.[2]

Dr. L. E. Holt has written a paper on the peculiar manifestations of malaria in children, and speaks of it as a field of observation which has been much neglected. He says that the organism of the child is peculiarly susceptible to malaria, and that it has been observed in epidemics that young children are the first to be affected, and that the poison acts more rapidly and more profoundly than in adults. The susceptibility also of the nervous, digestive, and respiratory systems produces such variations in the form and type of the disease as to mislead at times even those most careful in diagnosis, the symptoms referable to a particular organ often completely overshadowing the real disease, and giving an entirely new clinical picture. The attacks are at times so incomplete that even death may follow in the masked forms before the diagnosis can be made. Again the symptoms often come on so insidiously that the physician is not summoned until they have made considerable progress, and have obscured the diagnosis.

Dr. Holt's observation confirms that of Schmiedler, who states that there is scarcely any disease which is so changeable, obscure, and indefinite as intermittent fever in children, and that the closest observation on the part of both physician and attendants is often required to establish the fact of periodicity in the symptoms or the existence of a cold or sweating stage.

Dr. Holt confines his attention to the symptomatology and diagnosis of the disease, as he considers that the prognosis and treatment usually present no difficulties, and do not materially differ from the same in the adult. His experience is drawn from a study of one hundred and eighty-four cases, whose dwellings were in the most malarial district in New York. Ninety cases were males, and ninety-four females. One patient was under six months of age; six were under one year old; forty-five were between one and four years of age; fifty-four were between four and seven years of age; thirty-seven were between seven and nine years of age; forty-eight were over nine years old.

The invasion of malaria was found frequently to be more gradual than in adults, and in the abrupt cases the symptoms noted were convulsions, vomiting, drowsiness, prostration, fever, severe pains in head and epigastrium, splenic enlargement and tenderness, and occasionally hepatic tenderness. In the cases with gradual invasion there was anæmia, frontal headache, constipation, sometimes diarrhœa, anorexia, malaise, heavily furred tongue, epigastric pains, and nausea, drowsiness during the day and restlessness at night, slight cough, hot and cold by spells. The spleen in the great majority of cases, but not in all, was enlarged, and in many cases these symptoms occurred rhythmically every day or every other day, but often without any periodicity. The hour of invasion was noted in one hundred and six cases, and found in thirty-five cases to be in the forenoon, and in seventy-one cases in the afternoon or evening, thus differing from the disease in the adult, where this proportion is reversed. In the majority of cases the diagnosis could not be established by depending on a regular succession of chill, fever, and sweating. In one hundred and fifty cases the chill occurred in only nineteen, and in only about one half of these was it pronounced, and in only about one in five cases was there present anything resembling a cold stage. Fever was the most constant of all the symptoms, and varied as it does in adults; in its course it seemed to fall into three groups: —

First, those cases in which the temperature rose quite high at the outset, and remained so with very little variation for twenty-four, forty-eight, or seventy-two hours, when a marked remission occurred, and the fever then became distinctly remittent.

Secondly, those cases in which the fever was at first slight, and only noticed at some particular part of the day, usually towards evening or at night, but gradually increased in intensity, losing its periodic character until it became a continuous fever, with usually slight daily remissions, not rising at any time above 103° F.

Thirdly, those cases in which the fever assumed a distinct type from the outset, remittent or intermittent, and recurred regularly until controlled by quinine. The last was the rarest form. Out of one hundred and fifty cases the quotidian was in the proportion of five to one to the tertian, and there was no instance of the quartan type. In nearly one third of the cases no distinct type could be said to exist. In only one seventh of all the cases was the temperature found to have risen before the use of quinine above 104° F. In only three cases was it above 106° F. The highest recorded was 106¾° F.; this last was in an infant ten months old, and this fell on the following day to 101⅔° F. The average temperature was from 101° F. to 103⅓° F.

Sweating was noted in a little more than one quarter of the cases; it came later, and was much less marked than occurs in adults; it was profuse in seven cases. Cerebral symptoms of some form were the rule, and were carefully noted in ninety-seven out of one hundred and fifty cases; they were entirely absent in only four cases. Out of ninety-seven cases pain in the head occurred in

[1] Practitioner, November, 1882.
[2] American Journal of Obstetrics, January, 1883.

sixty-two, and was almost invariably frontal, and as frequent in the chronic as in the acute cases. Drowsiness or dullness, amounting at times to stupor, was the next most common head symptom. Convulsions were recorded in four cases, and in two cases occurred at the onset of the disease, and were not repeated; the ages were, one, a boy of eleven months, and the other a boy of four years. The third case was a girl twenty-one months old, in whom three convulsions took place on the same day within a few hours of each other. The fourth case was a boy, aged four months, who had five convulsions in three days. All of these cases terminated favorably, and in only one were the convulsions severe.

Vertigo was only noticed in three cases.

(To be continued.)

New Instruments.

A NEW FRAME SPLINT FOR HIP DISEASE.

BY F. S. WATSON, M. D.

It is a well-recognized principle, accepted, I believe, by even the most urgent advocates of the "up and about" treatment of hip disease, that there are periods in its course when enforced quiet to the affected joint offers not only the speediest relief subjectively to the patient, but also gives the joint its best chance for ultimate recovery. This is notably the case in the early stage of the disease, where the synovial lining of the joint is the primary seat of the affection, or where, in virtue of fluid pressure within the joint either from the presence of an increased synovial secretion or of pus which has made its way thither from a neighboring ostitis, pain is a prominent symptom.

Various appliances and apparatuses have been devised to secure partial or entire immobilization of the joint. And we have a number in use, from the weight and pulley extension to Bonnet's wire frame, Sayre's wire breeches, Thomas's fixation and Taylor's extension splints. Two ideas are prominent in these appliances. In one set the attempt is made to secure rest to the joint by, so to speak, incorporating the splint with the body and leg of the patient. And to this class belong the Thomas, etc. In the second class contraction of the thigh muscles is considered an important element in the production or continuance of pain, and this it is sought to overcome by efficient extension. All these appliances are open to criticism, *in so far as they profess to secure* efficient and complete rest to the joint.

The criticism, broadly stated, which is applicable to the first class may be expressed thus: It is impossible so to bind a splint to the leg and body of a patient that the patient and the splint shall not be capable of movements independent of each other, and at the same time permit of the splints being worn by the patient. And if the splint be not so applied, harm rather than good may result to the joint, owing to the varying pressure and friction transmitted to it by the independent movements of the splint and patient. One more important element is wanting in the construction of most of them, namely, extension and perineal counter-extension, which seems the most efficient manner of overcoming muscular contraction.

The weight and pulley supply simple extension, but are defective in securing rest to the joint in that the patient can raise the body on the joint, thus causing friction, can roll from side to side, thus bringing pressure on to the trochanter of the diseased side, and, moreover, lacks perineal counter-extension, without which definiteness of extension is lost. This we get in Taylor's admirable splint, which, however, when joint immobilization is desired, fails, because the patient can move the body on the joint or roll on to the trochanter. Seeing these defects, Dr. E. H. Bradford, of Boston, a few years ago had constructed a rectangular iron frame, between the sides of which stout cotton cloth was stretched, leaving an interval for the nates of the patient. Upon this frame the child could lie, and, wearing an extension splint, could be moved with much ease.

It was in the hope of going one step further toward securing joint immobilization that I have had the frame splint constructed, for a description of which I beg the courtesy of your columns.

FIG. 1.

A B, rectangular iron frame. C B, forming the lower part of the frame, is an adjustable foot-piece, which can be lengthened or shortened, and fixed at any point by a set screw on either side. D, movable iron arm bent to fit the curve of the thigh and placed above the knee to aid in preventing flexion of the thigh. E, adjustable upright, to which is attached a perineal strap, F. G, sliding plate, to which are attached the shoulder straps, H, on either side of the frame. The shoulder straps are connected by a strap running across the chest, which keeps them in place.

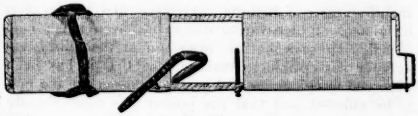

FIG. 2.

The same. The sides of the frame have been wound with cotton bandage, and stout cloth has been stretched across between the sides, leaving only an interval for the patient's nates.

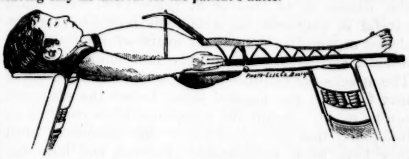

FIG. 3.

Shows the patient upon the frame, which rests upon two chair-backs. The extension straps are here in position.

When it is desired to place a patient upon the frame he is laid upon it, and the space to be left open in the cotton cloth for the nates is noted. The iron arm which crosses the thigh is slid along the frame to its proper position and there fixed. The same is done for the upright bearing the perineal strap and the plates bearing the shoulder straps. The patient is then removed, the frame wound with bandage, the cotton cloth stretched tightly across and sewed in the middle line behind. The patient is then placed upon the frame, as in Fig. 3. Extension is made by carrying the extension straps to a revolving bar with key and ratchet attachment in the foot-piece, upon which they are wound, exercising as much traction on the leg as may be desired. The perineal strap is adjusted before ex-

tension is made. The arms are passed beneath the shoulder straps, and the cross strap buckled.

When thus placed upon the frame the following points are secured: —

Extension and perineal counter-extension.

Impossibility of raising the body on the leg, or of flexing the leg on the body, or of rolling from side to side.

Entire freedom is allowed for movements of the arms and of the unaffected leg.

The patient can be moved from place to place with the greatest facility, undertake car journeys, be carried out-of-doors, etc., with the minimum of disturbance to the joint.

The sphere of action of this frame is limited. When deformity is already present it has to be overcome before the splint can be advantageously used. This is best accomplished by making extension in the line of deformity. This splint does not, of course, replace in any way the appliances which allow of the patient's moving about, which in a later period of the disease is so important a part of the treatment.

The frame has now been worn by three patients, in each case with relief from pain, with the greatest comfort to the children, and with an entire absence of any injury resulting from pressure on any part of the body. When the patient is lying upon the frame on a mattress the sides of the frame sink into the bed just far enough to prevent any injurious pressure from them. It is not necessary to employ very powerful extension, and hence no complaint is made of the perineal strap, so that we may safely say that sloughs will not result from its use. In the first case in which it was employed the patient lay upon it for two months, and constantly derived the greatest comfort from it.

Two measurements are necessary for the construction of this splint, — the patient's length and the width between the acromion processes.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

SURGICAL SECTION.

H. C. HAVEN, M. D., SECRETARY.

October 28, 1882. Dr. R. M. Hodges presiding. Dr. T. S. Watson presented

A NEW SPLINT FOR HIP DISEASE.[1]

Dr. E. H. Bradford said that he had seen the splint in practical operation for the last six or eight months, and it seemed to him to afford the best method of fixation of the joint, better than Bonnét's goultière or Sayre's wire breeches. Dr. Bradford had sometimes found it advisable, in the case of an active child, to restrain the movements of the well leg by another knee piece similar to that described for the affected side. The patient whom Dr. Watson had shown was in a wretched condition when admitted to the hospital, whereas now her condition was excellent, as could easily be seen from her appearance.

Dr. C. D. Homans asked if those using the splint had not been troubled by abrasion caused by the perineal strap. Formerly an apparatus somewhat similar to this was used extensively in fracture of femur; that is, extension by ratchet and counter extension by perineal strap. This apparatus was given up on account of the abrasion caused by the perineal strap, and it seemed to Dr. Homans probable that the same trouble would be met with in using the splint of Dr. Watson.

Dr. Bradford replied that he had not as yet met with any cases either in hospital or private practice where he had been obliged to forego the use of the splint on this account.

Dr. C. P. Putnam thought the amount of pressure practically brought into the perinæum had been overestimated. He had once tested the amount that a child's perinæum could bear, and found that twelve pounds could be borne for a short time, but before long gave great pain. He thought it would be found that the pressure was seldom over six pounds.

The management of the perineal strap was comparatively easy while a patient was in bed, or while using an apparatus that did not bring the weight of the body into the strap, but much more difficult when a patient was walking with a long hip splint.

Dr. Marcy agreed with Dr. Putnam in his view that a small amount of force was all that was necessary to secure the desired result.

In regard to the objection of Dr. Homans, Dr. C. P. Putnam thought the method of applying the perineal strap made a great difference; formerly it was carried upwards on a slant, in front as well as behind, and pressed hard against the edge of the adductors. Now it is usually attached, as in the apparatus just exhibited, at a point somewhat in front of the groin and carried up in front vertically, as had been explained by Dr. Bradford. In this way it was far easier to avoid sores than by the old method.

Dr. Cheever asked if this apparatus had ever been adapted to the treatment of Pott's disease. Dr. Watson replied that a similar splint had been used for that disease, but without the ratchet extension. Dr. Cheever thought that by fixing the body and applying extension to the legs this same splint would be admirably adapted to the treatment of caries of the spine.

Dr. Bradford stated that although extension by the ratchet had never been utilized in treating Pott's disease, extension had been gained by fastening the patient's head to the head of the bed, which was raised, the sag of the body thus giving counter-extension.

Dr. Cheever thought the advantage so great of being able to carry a patient so conveniently as can be done on this splint either out-of-doors or wherever it is desired, as to merit its careful trial in case of spinal caries.

In reply to a question, Dr. Watson answered that the patient exhibited had worn the splint shown for six weeks without changing.

Dr. Hodges said the remarks of the evening showed the general distrust which surgeons have of any new apparatus, some unexpected part turning out to be defective, and provoking the unfortunate effects of pressure, and often in the last place where it would be suspected.

In regard to the objection that the iron sides would be a source of trouble, Dr. Watson said that children had been kept on them for months at a time without the slightest abrasion.

Dr. Bradford mentioned the necessity of the splint being wide enough to take its bearings entirely

[1] Vide page 84, this number of the Journal.

outside of the bony prominences of the tuberosities of the ischii. In using this apparatus for caries of the vertebræ it was often necessary to raise either end of the splint to keep the prominence of the spine from pressing against the bed.

DR. PUTNAM testified to the freedom from any results of pressure in the cases he had seen wearing this form of apparatus. He thought a great deal of the trouble in apparatus arose from their manufacture being left to the instrument maker instead of the surgeon seeing that each apparatus was adapted to the need of each particular case.

DR. E. H. BRADFORD read a paper entitled

THE SURGICAL TREATMENT OF INFANTILE PARALYSIS.[1]

DR. J. J. PUTNAM agreed with Dr. Bradford as to the importance of orthopædic treatment in infantile paralysis, and as to the incompetence of instrument makers to decide upon the nature of the apparatus which is needed, every case requiring special and prolonged attention. He had found that unless the paralyzed limbs can be kept in a good position, and the means secured to the patient of making a practical use of what little muscular power may remain to him, the various methods for increasing the nutrition of the muscles will be of little or no avail.

DR. BRADFORD said that it was difficult to compare the results obtained from tenotomy and stretching, as no two cases were just alike; they had seemed equally good, and it was with him more a question of expediency; in hospital practice he usually tenotomized, as time was saved thereby; in private practice, on account of the inconvenience of an operation, he stretched. The tendons usually requiring to be cut were the hamstring and the tendo-Achillis. Dr. Bradford had never met with any injury to the veins caused by stretching.

DR. H. O. MARCY read a paper entitled The Best Methods of Operative Wound Treatment, reserved for publication.

BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

THE Society held its eighteenth regular meeting at the house of Dr. G. F. Jelly, November 2, 1882, DR. GOLDSMITH occupying the chair.

DR. HENRY R. STEDMAN read the paper of the evening, entitled

A CASE OF ACUTE CHOREA, WITH PROFOUND MENTAL DISTURBANCE.[2]

In the discussion which followed this paper DR. COWLES asked Dr. Stedman about the physical condition of the patient. He replied that he was anæmic and reduced in flesh.

DR. JELLY asked if the paroxysms occurred at a particular time in the day. He asked because he had recently seen a case of mixed chorea and hysteria in a young girl, in which the twitchings generally came on at night and continued until large doses of sedatives had been administered. Reflexes were good in this case, but there was impairment of sensation, and she could not stand, in consequence of lack of muscular power. She improved under massage and tonics.

DR. TUTTLE recalled the case of a young man of about nineteen, who was brought to the city hospital, in which mental disturbance complicated chorea. This disturbance increased, the patient becoming quite violent, and dying of exhaustion.

DR. STEDMAN mentioned a case of violent chorea cured by chloral.

DR. DENNY said that during the last three or four years he had seen quite a number of cases of chorea in school-children. The teachers of these children first noticed irritability and want of self-control, followed by a certain degree of mental impairment, particularly in children who were naturally bright. These children were often easily frightened, sometimes crying without cause; occasionally they were exalted. In some cases there was no mental change. The pathology of these cases is obscure. It would seem to be explained by a want of equilibrium in the posterior cells of the spinal cord, also to lesion of the optic thalamus, or corpus striatum. He had taken particular pains to observe the order of the development of symptoms in upwards of sixty cases of chorea, occurring at the beginning of the attack, and found that they followed the order of the localization of the centres in the motor zone of the cortex. Chorea affects the whole cerebro-spinal system, and usually occurs when the body is undergoing development.

DR. GOLDSMITH said that the case reported was functional in character and of a very unusual type in regard to age, sex, family, individual history, etc. In his experience he had seen eight cases of chorea in adult insane persons, and in all but one of these the disease was limited to a small group of muscles.

DR. CHANNING read a few notes on the

MEDICAL TREATMENT OF INSANITY, WITH SPECIAL REFERENCE TO OPIUM.

DR. COWLES said his experience with morphia had not been satisfactory, and he rarely used it for its sedative effect.

DR. JELLY had found morphia useful in certain cases of melancholia with agitation, but it had otherwise disappointed him.

DR. TUTTLE had not seen a case improve under the use of morphia.

DR. DENNY said he did not now recall cases in summing up his experience from year to year, where opium had been of much benefit.

DR. STEDMAN thought that in some cases of melancholia with excitement, opium in small doses during the day was of benefit.

DR. CLOUSTON used little opium, preferring a mixture of bromide of potash and cannabis indica.

DR. GOLDSMITH said that the English preparation of cannabis indica seemed much stronger than that which we got in this country. He thought that opium was sometimes very beneficial in cases of melancholia with great distress and anxiety.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.[1]

C. B. NANCREDE, RECORDER.

CARCINOMA OF THE STOMACH, *continued.*

Case II. Scirrhus of the pylorus; symptoms simulating idiopathic anæmia.

F. R., aged fifty-four, white, German, resident of a healthy locality, but much exposed as lumberman during the winter. Addicted to constant use of spirits, malt liquors, and tobacco. Had a fever of six weeks' duration at the age of sixteen years, and eight years ago some pulmonary inflammation. Never had malaria or syphilis. Does not know cause of mother's death; seven brothers and sisters healthy; father died of old age; his own three children living and healthy. Admitted to University Hospital, December 20, 1878. During the previous winter had numerous gastric attacks, as shown by pain and loss of appetite. In the spring and summer he lost flesh and strength, and was subject to pain in the bowels and in the hepatic area, flatulence, pyrosis, and constipation, but never vomiting. On account of salivation, in June, he became especially debilitated. At time of admission weight one hundred and eighteen pounds, usual weight one hundred and seventy. Lies on left side perfectly apathetic, with the physical and mental processes slow of action. Extremities cold, very anæmic; conjunctiva and mucous membranes very pale; sclerotics pearly white; complexion of a sallow, dirty hue; palpitation of the heart, dyspnœa, and subjective ear noises were noted; temperature irregular; appetite poor; flatulence and pyrosis; pain and tenderness in epigastrium; no definable tumor, but a sense of induration; hepatic and splenic areas of dullness normal; no venous hum; heart sounds weak. Urine: specific gravity 1018; neutral reaction; albumen one sixth; no casts, bile, or sugar; phosphates not in excess. Blood: white corpuscles in excess, red greatly decreased in number. Ophthalmoscopic examination: slight retinitis; optic disk pallid; central artery dilated; venous blood paler than usual; absorption of choroidal epithelium, allowing choroidal circulation to be seen; macula healthy; no hæmorrhage throughout fundus; both eyes present the same appearances. A low typhoid state soon developed, with diarrhœa and excessive flatulence. For three days prior to death vomiting occurred. He died December 30, 1882.

Autopsy. — Stomach alone examined. It is to be regretted that the full record was lost. Stomach adherent to liver and transverse colon. Lesser curvature from pylorus half way to cardiac orifice, infiltrated with cancer, extending two inches over the anterior wall, and at the pylorus encircling the organ. Pancreatic and biliary ducts pervious; microscopically the growth was found to be scirrhous carcinoma.

Remarks. — On account of the profound anæmia and the absence of tumor and vomiting, idiopathic anæmia was considered. The examination of the blood and the condition of the eye ground, contra-indicated such a diagnosis. The normal size of the liver and spleen and the non-glandular involvement excluded leucocythæmia. It is to be regretted that the exact numerical blood count was not recorded.

In this case the lesser curvatuere was very much involved, and a distinct tumor was absent, quite the opposite of Case I.

[1] Concluded from page 62.

TUMOR OF BRAIN.

Presented by Dr. A. P. Brubaker for Dr. H. Leaman.

J. J., aged fifty-three, laborer. When first seen the patient was lying on his back, with head drawn backwards into the pillow, and complaining of stiffness and soreness in back of the neck. The mouth was widely opened and parched, and the breathing deep and heavy. He was in a semi-unconscious condition, from which, however, he could easily be aroused, but soon relapsed into his former state, which was attended by stertorous breathing. Speech and deglutition were both interfered with, but not abolished. There was involuntary passage of urine, but the bowels were constipated. Venereal ideas were excessive, but accompanied by complete impotence. Voluntary movements of the extremities and also the power of coördination were considerably impaired. Pulse and temperature were normal. Liquid food was taken with difficulty. His condition had been as described four days previous to my first visit on September 4, 1882. The symptoms gradually increased and coma supervened, which ended in death September 17, 1882. Following history was obtained from the family: Twenty-six years ago the patient was confined to bed with "nervousness" for a period of two years, when he passed a calculus about the size of a date seed; again, a month later, another smaller one atop. His bladder continued to give him more or less trouble up to death. He had his clavicle broken nineteen years ago, but there was no injury to the head. About sixteen years ago he was suddenly seized, while at work, with a severe headache, and became totally blind, which lasted for twenty-four hours. This was relieved by wet cups to back of the neck. From that time he was subject to what they called "shaking spells;" when standing there would be a violent trembling of the knees and shaking of the arms. These attacks occurred about once a month, and occasionally three or four times a day. They increased from year to year in frequency and severity, and appeared to be excited by high winds and storms. In February, 1882, he was seized with paralysis, beginning in the left little finger, thence gradually extending to the ring and middle fingers, until the hand became powerless, but was able to move his arm. Then followed a numbness in the outer side of the left side, attended by impairment of the power of coördination, so that on attempting to walk he was compelled to run to keep from falling. He frequently fell in the street, and had to be carried home. Last February loss of speech supervened, which lasted for one month; the patient then began to speak in monosyllables, after which speech gradually returned.

Autopsy. — Congestion of the entire brain. By removing it four or five ounces of serum ran from the cranial cavity. Brain substance seemed to be normal throughout. In the right fissure of Sylvius was embedded a tumor about an inch and a half in diameter, which was almost entirely concealed from view by the convolutions. It rested upon the convolutions of the island of Reil, completely disorganizing them atop. The inferior extremities of the ascending frontal and parietal convolutions were normal. The upper surface of the temporo-sphenoidal lobe was somewhat disorganized. The tumor apparently sprang from the pia mater.

Report of the Committee on Morbid Growths. — A section made from the tumor presented by Dr. Brubaker, and examined microscopically, showed that the growth was tubercular. Its histological structure is

seen to consist of fibrous tissue constituting a reticulum, the meshes of which are filled with lymphoid cells. These appearances are very distinct at the peripheral zone of the tumor, while the centre and inner zone are in a state of retrograde metamorphosis, presenting a very granular appearance, scarcely stained by the carmine. The blood-vessels are mostly obliterated, their lumen being filled with coagulated blood or granular débris.

ENLARGED LYMPHATIC GLANDS.

Exhibited by DR. W. H. PARRISH.

I show five lymphatic glands removed from the axilla of a patient whose breast I amputated about nine months ago. The case was then reported at the Obstetrical Society, and was published in the *Medical News* of July 8, 1882. The specimen was referred to a committee, and Dr. Beates made a microscopical examination and concluded that the growth was an adenoma that had undergone carcinomatous change. Of the enlarged glands presented this evening, three, about the size of an almond, were removed from the axilla, a fourth, of smaller size, from just below the clavicle, and the fifth from the side of the neck about an inch from the clavicle. The patient presents no cachexia. The specimens were referred to the Committee on Morbid Growths.

POLYPI FROM THE UTERINE CERVIX.

Exhibited by DR. W. H. PARRISH.

I also present this evening two small growths each about the size of the last phalanx of the thumb, removed to-day with a wire écraseur. On Christmas Eve I saw for the first time a patient of French birth, a teacher, apparently about thirty-five years old. When I entered her room she was in a state of syncope from hæmorrhage from the genitals. The hæmorrhage had, however, ceased. With the application of hot, wet cloths over the front of the chest, and by hypodermic injections of whiskey and aromatic spirits of ammonia, she in a few minutes revived, so as to be able to tell me that she had not menstruated for three months, when suddenly bleeding began from the womb, and continued during the day with an exacerbation just before sending for me. As the patient's condition was evidently a critical one, I asked the direct question if she had not had or was not having an abortion. She said it was impossible. I then learned that she was single, and forty-two years old. A digital examination showed an intact hymen, and a substance in the vagina that at first touch felt very like an embryo of about three months. But I soon recognized that it was a growth attached to the lower part of the cervical canal, and that there was another distending the cervical canal. The latter felt still more like an embryo or ovum, and in fact in the absence of the one in the vagina might have at first misled me into thinking that the patient was aborting. Slight traction on it soon showed that it was attached. There was no return of the bleeding, and to-day, with the assistance of Dr. M. O'Hara, I removed both the growths with the wire, and without etherization or the use of a speculum.

A remarkable feature of the patient's history is that she had always menstruated scantily, and at intervals of five or six weeks. Never before had she evinced a tendency to uterine hæmorrhage. I am confident that the patient was not pregnant. I presume that being virginal she is approaching the menopause.

NORFOLK, VIRGINIA, MEDICAL SOCIETY.

W. A. THOM, M. D., SECRETARY.

THE regular monthly meeting of the Society was held at the office of Dr. Thom, January 4, 1883, at eight P. M. The President, DR. ALEXANDER TUNSTALL, being absent, DR. SHEPHERD, the Vice-President, occupied the chair. There was quite a full attendance. After the usual business DR. F. B. STEPHENSON, U. S. N., present by invitation, read the following case: —

DEATH IN OLD AGE FROM CARDIAC SYNCOPE, WITH LESION OF BOWELS PRESENTING SYMPTOMS OF INFLAMMATION.

T. R., aged eighty-one years and six months, was a sailor, of robust constitution. He had left indirect inguinal hernia (caused by a fall, for which he had worn a truss since 1868) of considerable size. There was sound of left auriculo-ventricular insufficiency. He had good general health, had been able to walk several squares easily, do slight work about the garden, and go up and down stairs until one year ago. He then noticed a feeling as if "asleep" between the fingers of left hand, with subsequent slight sensory paralysis, which gradually involved the entire arm and shoulder.

December 4, 1882. Without known special exciting cause he this morning felt sensations of fullness, weirdness, heavy headache, in brain, more marked about calvarium. He spoke of occasional transitory pains in chest. The radial pulse was atheromatous. His bowels had been sluggish for years. He lay on couch this day, though able to walk about the room. The night previous he took a mild cathartic to relieve the usual constipation.

December 7th. The stools became frequent and slimy. He complained of general feeling of cold, and especially along the spine.

December 8th. The stools became bloody, with some pain in abdomen. He could retain nothing in digestive tract, a rectal discharge occurring very soon after swallowing liquid; solids he could not take.

December 9th. He became decidedly weak and haggard. Same condition of bowels maintains.

December 11th. Right arm became sensorially paralyzed, as the left. He used milk diet, with powdered ice and small portions of brandy. He complained of external and internal heat, the latter being relieved by the ice somewhat.

December 12th. There was difficulty in swallowing, apparently due to paralysis. Linseed tea, and that from the bark of slippery elm, was retained best by stomach. He took small quantities of corn starch and brandy, and powdered ice. Sense of taste became dulled; water was insipid. He could not sleep. Feeling of warmth in stomach he spoke of, which ice modified. The stools were painless, involuntary, bloody, and slimy. Urine was slight in quantity and highly colored. The radial pulse was more compressible. The system had received very little nourishment during the previous five days. He spoke rationally.

December 13th. At three o'clock A. M. he experienced a sinking. Death seemed very near. The mouth was drawn awry, lower right corner being depressed. At ten o'clock A. M. he was able to swallow small portions of brandy and water. He then had recovered the power of speech, which was lost during previous

hours. At three o'clock P. M. he talked rationally, though slowly, and with difficulty. He complained of internal warmth, and put his hands against those of callers to cool the feverish skin, though he had very little power in his arms. The radial pulse was more rapid and more compressible. He had occasional feeling of fullness and oppression in stomach, which was relieved when something within seemed to pass downward. The stools were involuntary.

December 14th. About eleven o'clock P. M. yesterday he insisted on sitting up. The moment he did so he died. Over the sacrum was a commencing bed sore. The rectum protruded about three inches.

Treatment had been symptomatic. Death was probably due to cardiac syncope. The symptoms of brain involvement, of cardiac disease, and of intestinal inflammation, merit thought when considering the influence of respective lesions in effecting the final result.

In the discussion following Dr. Stephenson's paper DR. SHEPHERD thought that death was due to heart clot; that a small clot in brain may have caused the diminution of nerve force in right arm.

DR. NASH related a case in his experience in which there was repeated coma, consequent on brain tumor, when he kept the patient alive several weeks by use of stomach pump. He spoke of cases of sudden fatal syncope in individuals convalescent from serious illness, instancing a death while at stool of a recovering pneumonitic patient. He had observed copious fluid discharges after large doses of opium. He stated the frequent occurrence of hypostatic congestion in the lungs in the convalescing stage of acute disease.

DR. SHEPHERD suggested that enervation might be aprimal cause of the bowel symptoms.

DR. STEPHENSON desired to know the opinion of those present on the following subject: Is this a case of senectus; are the symptoms of paralysis of muscles of deglutition and the intestinal complication directly consequent on the marasmus of old age and its subsequent weakness of nutritional power?

DR. THOM considered the weakness natural to old age the primal cause of these lesions, and, ultimately, of death.

DR. SUTTON was decidedly of opinion that old age *per se* may be a cause of death, independently of intercurrent or consequent disease; that, *pari passu*, loss of mental power or weakness of memory is as much a sign of senility as failure of muscular power or inability of digestion.

There being no further matter for discussion the Society duly adjourned.

Recent Literature.

A Guide to Therapeutics and Materia Medica. By ROBERT FARQUHARSON, M. D. Enlarged and adapted to the United States Pharmacopœia by FRANK WOODBURY, M. D. Third American edition. Philadelphia: Henry C. Lea's Son & Co. 1882. 526 pages.

The arrangement of the third edition of this well-known compendium is essentially the same as that of previous ones. The rules for prescribing, which form the greater part of the introduction, are excellent, and will be found instructive by every student.

In a work which does not pretend to be exhaustive the authors have been able to omit many botanical and pharmaceutical details, but in view of the space devoted to less important drugs more than two lines could have been spared for the therapeutics of apomorphia. Hydrobromic acid is not mentioned. It would have been well to have specified that the book is adapted to the United States Pharmacopœia of 1870. The additions made by the American editor are especially valuable. The book is one which has been and will continue to be much used by students and younger practitioners, but they should remember that it does not enable them to dispense with a more complete treatise.

A Manual of Medical Jurisprudence, Instructing how to Conduct Inquests and Post Mortems, and how to give Official and Expert Testimony before Courts of Law in Cases of Homicide. By C. H. VON KLEIN, A. M., M. D. Hamilton, Ohio. 1882.

This little pamphlet of thirty-five pages (including title-page and preface) should have been printed upon brown paper, with ragged edge and musty odor. Its author says, with some degree of truth, that "nothing of the kind has ever been published in this country." Of how much value it may prove to the forensic physician may be learned from one or two extracts:—

"Death is always the inseparable effect of a wound absolutely mortal." Page 22.

"*Analysis for arsenic.* A portion of the mass is to be mixed with a quantity of *suet and salt of tartar*, . . . and melted over a fire; if a reguline metallic substance is produced at the bottom it is clear that arsenic is contained in it."

"It may be inquired whether this metallic substance being melted again with *metals of a red color* turn them to a white; this is likewise proof of arsenic." Page 19.

Forensic medicine is a progressive science, and the publication of an old treatise of the eighteenth century under the guise of a modern work, with the plea of usefulness to the medical profession, is a species of literary quackery which deserves just censure.

Eighteenth Annual Catalogue of the Massachusetts Institute of Technology.

This catalogue shows the institute to be in a prosperous condition, and to be doing a useful work under able instructors. Course VII., consisting of three years, the details of which are given on page 40 of the catalogue, offers excellent preliminary training for young men intending subsequently to study medicine.

Transactions of the Thirty-Sixth Annual Meeting of the Ohio State Medical Society, held at Columbus, June 14–16, 1881. Also, for the Thirty-Seventh Annual Meeting, June 13–15, 1882. Columbus: 1882.

This is a volume of 375 pages, and reaches us some eighteen months after one of the meetings which it chronicles occurred. For this reason the portions of the book devoted to reports of progress on special subjects lose a certain amount of the value which they may originally have possessed. Other articles are of varying interest. Throughout the book are interspersed an unusual number of blank leaves, which are not, however, the most valueless pages it contains.

Medical and Surgical Journal.

THURSDAY, JANUARY 25, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

ANNUAL REPORT OF THE PRESIDENT AND TREASURER OF HARVARD UNIVERSITY.
1881–1882.

THE portion of this annual report of Harvard University emanating from President Eliot is of more than usual interest, which is saying not a little, as his presentation of any subject with which he concerns himself is always terse and vigorous.

In regard to the Medical School, we learn from the report of the dean that the whole number of students in attendance during the year was two hundred and fifty; during the first term two hundred and forty-six; during the second two hundred and thirty-five. Of these, one hundred and twenty-eight had a literary or scientific degree. There were ninety-five applicants for the degree of Doctor of Medicine, of whom eighteen were rejected. Seventy-seven passed the examination, and received their degrees.

The fourth class was composed of ten students, of whom nine passed the examination, five of these *cum laude;* three received hospital appointments; one took the ordinary degree of M. D.; one postponed graduation to become a candidate for a hospital.

NUMBER OF TERMS SPENT AT THE SCHOOL BY GRADUATES.

	1873	1874	1875	1876	1877	1878	1879	1880	1881	1882

Total graduated.	41	88	30	36	61	48	70	45	60	86[1]

[1] Includes nine students of the Fourth Class.

The foregoing table is given as showing the increasing recognition of the necessity of studying medicine where it can be taught.

"The remarks made in the last report with regard to the fourth year might be repeated in this. It is still too early to determine the results of this additional effort to improve medical education. We can only say that, if expressed intention of prolonging the term of study be an index of progress, progress has been made. The chief difficulty still remains; we are in competition with the hospitals, which claim an important number of the best students before they have completed a proper course of study."

The Dean of the Dental School reports twenty-one students in attendance. The standard of the school is high, and its training thorough, but it suffers from very pressing impecuniousness, so that its teachers serve absolutely without pay.

In regard to the new Physical Laboratory, the President says that: —

"The subscription of $75,000 for its endowment was made up during the past summer, and $22,000 were paid in by September 1st. The condition of the anonymous gift of $115,000, wherewith to build a suitable laboratory, having been thus fulfilled, the Corporation set about the preparation of the plans for the building, Mr. Alexander Agassiz having general charge of the undertaking as a committee of the Corporation. The professors and instructors in the department of physics have all given careful attention to the plans, and it is confidently expected that spacious, well-arranged, and thoroughly equipped laboratories, ample cabinets, and convenient lecture-rooms will be the product of their studies. The building will probably be begun in the coming spring."

The Museum of Comparative Zoölogy received very important accessions during the year.

The director of the Chemical Laboratory reports great activity there, not only as a place where elementary and advanced chemistry are taught to a large number of students, but also as a place of research, where the knowledge of chemistry is constantly extended by the diligent labors of professors, assistants, and students.

As was previously mentioned in our columns, some months since a professorship of Veterinary Medicine has been established in the university, and Mr. Charles P. Lyman was appointed to the chair. Since the opening of the current academic year a faculty of veterinary medicine has been organized, a course of instruction covering three years has been arranged, and in September, 1883, pupils will be received. The objects which the university had in view in organizing this new department were briefly these: —

To train, year by year, a few competent and trustworthy practitioners, and to contribute to the progress of a branch of science which deals with many questions of public health and with great pecuniary interests.

The following table exhibits in per cents. the occupations, or professional destinations, of twelve hundred and twenty-six recent graduates, the survivors of ten classes (1867–1876), as stated in the class reports issued (with one exception) three years after the year of graduation: —

	Law.	Medicine.	Theology.	Scientific.	Teaching.	Business.	Unknown & Miscellaneous.
Per cent. . . .	36	10	5	6	9	21	13

The President reviews at some length the controversy in the Board of Overseers with reference to the admission of women to the Medical School. It is unnecessary that we should revert to this again.

"Late in the year," President Eliot tells us, "the Faculty appointed a committee to consider and report upon the general subject of out-of-door athletic contests, and particularly upon the regulation of match games of ball. It was the elaborateness of the arrangements for match games of base-ball, and the frequency of those contests in April, May, and June which prompted this action on the part of the Faculty, but the inquiry at once took a wide range, and comprehended all the competitive athletic sports."

Subsequently a standing committee of three was appointed to regulate athletic sports. The investigations, conclusions, and regulations of these committees form, we think, perhaps, the most interesting part of this annual report, and we are forced by the crowded state of our columns to defer any extended notice of them to our next issue.

ANNUAL REPORT OF THE NEW YORK STATE BOARD OF CHARITIES.

THE sixteenth annual report of the New York State Board of Charities has just been presented to the legislature at Albany. The institutions subject to the visitation of the Board are of three classes: Those founded and supervised by the State, those supported and managed by cities and counties, and those under the control of incorporated benevolent associations. A large part of the work of the Board during the past year has been in connection with asylums for the insane. The State institutions have been generally inspected by the Standing Committee on the Insane, and frequent visits have also been made to them by special committees and members of the Board, while most of the city and county institutions have been visited by the commissioners of the respective districts, and by the secretary, who, under the direction of the Board, has made numerous examinations of the inmates and working of these institutions. The report states that the suggestions of the Board in regard to needed improvements or changes in modes of administration have generally been well received and acted upon, and that many improvements in the management and care of the insane, especially in the county institutions, have thus been effected during the year. The following details are given in regard to the institutions: —

The several State hospitals for the acute insane have capacity for 1600 patients. The Hudson River State Hospital and the Buffalo State Asylum are each planned for 600 patients; so that the completion of these institutions, according to their respective designs, would give a total capacity for the custody and treatment of 2200 acute insane, by the State. During the past year these institutions, it appears, had an average of 1302 patients under treatment, and the number in their care October 1, 1882, was 1311. It will thus be observed that they had an average excess of accommodations for 298 patients, during the year, and that they contained at its close spare room for 289. It is believed, therefore, that no further appropriations for the enlargement of the State hospitals for the acute insane are needed for the present. It appears that the State has asylum accommodations for 2150 chronic pauper insane. It is districted between the Willard and Binghamton asylums, and they receive this class only, the patients being transferred from time to time from county poor-houses and the several State insane hospitals. The per capita charge to the counties for the maintenance and care of the insane in these institutions, fixed by statute at the actual cost, was, the last fiscal year, $2.65 per week. The reports of the Willard Asylum show that from its opening in 1869, its accommodations have been taken by the counties as fast as made, and it is now practically full. The Binghamton Asylum has been opened less than fifteen months, and it had 285 patients in its care January 1, 1883; thus leaving room for only 85 more patients. According to the returns of the superintendents, there were 1956 chronic pauper insane in the various county poor-houses and asylums October 1, 1882. Of these, 1212 were in counties exempt from the Willard Asylum Act, and 744 in the other counties; in most of which little or no provision exists for their proper oversight and care. Upon the whole, the buildings in use for the chronic insane of the exempted counties are now in fair condition and comfortable. There is a tendency in the most of the counties, however, to put off making the needed improvements as they arise, and it requires constant watchfulness on the part of the Board to see that these are not neglected, and that a proper standard of care for the insane is maintained.

The condition of the insane of New York City has been carefully examined during the year by the New York commissioners, a committee of the Board appointed for the purpose. It was found that the accommodations for this class, especially in the men's department, were greatly crowded, and that they could not be well extended in the locality upon the islands, owing to the lack of sufficient lands. The committee, therefore, recommended the purchase of a farm outside of the city, and the erection of plain and inexpensive detached cottage buildings upon it, with a view to the removal of a part of the chronic insane to them; and the Board of Estimate and Appointment, as previously mentioned in the JOURNAL, has already made an appropriation for the purpose of carrying out these objects. This will give facilities for the out-door employment of the insane, and at the same time relieve the crowded condition of the present accommodations.

The State asylum for idiots, at Syracuse, had an average of 305 pupils under instruction during the year, and the custodial branch for feeble-minded girls

and young women, an average of 125 inmates. This institution has greatly relieved the poor-houses of this class, and as the rate of maintenance and care is only about the same as in these institutions, it can no longer be regarded as experimental. There are still considerable numbers of idiotic and feeble-minded young girls in the poor-houses, and it is recommended that the institution be extended so as to meet the requirements of all this class.

THE NEW HOME FOR INCURABLES AT BRIGHTON.

THE JOURNAL has on more than one occasion spoken of the desirability of an institution for the care of the incurably sick. They are necessarily numerous in a large city, and of equal necessity is it that a large proportion of such hopeless cases should happen among that portion of the community who are dependent upon their own labor for existence, and, in consequence, when disabled are thrown upon the charity of the world for support.

An ordinary hospital is by no means the proper place for such a class of cases, such an institution is rather intended for acute diseases, in which the event is soon decided; were its beds filled with patients whose malady must last for years it would deprive many times their number of acute cases of the advantages of hospital treatment.

Many of these invalids are equally out of place in an almshouse. They are often among our most worthy poor, whose misfortunes appeal most directly to our sensibilities, as they seem most truly the victims of a mysterious dispensation whose cause and whose object are past finding out. These are certainly a class of cases which every one who has had anything to do with charitable institutions has found it particularly hard to deal with. A savage nation might perhaps solve the problem by a blow on the skull, not entirely with a view to euthanasia, but because the victim had ceased to be productive. To a Christian nation such a course is forbidden, and rightly, for it finds use for those whose physical perfection has been blighted. What lessons of patient endurance, what sweet resignation is often found by the bedside or the arm-chair of the chronic invalid! Who cannot call to mind some white-haired sufferer, whose abode became a centre from which light and happiness was radiated throughout a whole community! To one who can recall but a single example of this sort it suffices to give an interest in the whole class of individuals who drag out weary years which bring no promise of amendment.

The recent establishment of a Home for Incurables will, we are sure, meet the approbation and encouragement of the community. Perhaps we should have been inclined to believe that such an institution would thrive better in connection with an older and well endowed hospital, for we are somewhat skeptical as to the propriety of the multiplication of small unendowed hospitals; but we are informed that the maintenance of the present institution is already assured for a series of years, and we believe that all interested in the establishment of such a charity may well look to the one now putting forth its claims, as the nucleus of what shall some time grow to be the much-needed shelter for this very interesting class of invalids. We understand the management have decided to limit the benefits of the hospital to those entirely dependent upon charity, as in this way they believe they will make the best use of their necessarily limited accommodations, which as yet are only open to those of the female sex.

TRUSTEES OF STATE LUNATIC HOSPITALS.

WHATEVER may be the qualifications of his successor, and we know nothing of them, in not reappointing Dr. C. F. Folsom as a trustee of the Danvers Lunatic Hospital Governor Butler has deprived that institution of very valuable and faithful services. Dr. Folsom has taken great interest in the hospital, visiting it very frequently, and serving it in ways open to any active and zealous trustee, securing to it by personal application the interest of many benevolent people, who have contributed generously to the entertainment of its inmates by furnishing a billiard table, piano, and large numbers of pictures, books, illustrated periodicals, etc. As an expert in matters connected with mental diseases, however, Dr. Folsom has been useful to the hospital in ways not open to non-medical trustees. He was largely instrumental in procuring the appointment of a board of visiting physicians, and his opinion and advice have been at the disposal of both trustees and superintendent on all medical matters.

Now, although it certainly is not desirable that the majority of hospital boards whose chief function is a financial supervision should be medical men, it quite as certainly is desirable that some expert other than the superintendent should have an intimate knowledge of the condition of the hospital, and be able to advise the trustees intelligently and with freedom from any personal bias when they take action on matters more or less professional in character, and therefore that such expert knowledge should be at least represented on these boards. Such connection of an expert with the boards of trustees of our lunatic hospitals is particularly desirable where there are no expert lunacy commissioners, and no intelligent expert opinions are accessible to trustees except those of the resident medical officers.

An honorable and competent expert acting as trustee, really secures to the State, so far as his hospital is concerned, more than the usual advantages of a paid lunacy commissioner, without expense. In such a case as that which furnishes our text it is not the outgoing trustee but the State's hospital which is the loser.

— Medical professor to raw student: "Where is the glottis?" "I don't know, sir. I think you put it on the shelf in the dissecting room with the rest of your surgical instruments."

MEDICAL NOTES.

— A writer in the *British Medical Journal* recommends hyoscyamin subcutaneously as a sedative for maniacal persons, and says that while hyoscyamus is without efficacy in such cases, the alkaloid will usually quiet the violent manifestations without leaving any disagreeable after-effects or arresting the secretions. The beginning hypodermic dose should not be greater than one fifteenth of a grain.

Another hypnotic, recommended as useful and free of injurious effects, is the tannate of cannabin (see *Practitioner*, November, 1882). Of sixty-three cases in which it was used for insomnia attending chronic diseases, good results were obtained in thirty-seven and moderately good ones in fifteen. The average dose is about five grains.

— We notice that a contemporary writer, speaking of the inhabitants of Murray Hill, says that none appear to have so secure a seat as the owners of patent pills. It is but natural. Other patented articles outlive their usefulness; pills never. Petroleum is a slippery vanity, real estate but a shifting sand. For permanence and stability, next to having your treasure laid up in heaven, put it into a proprietary medicine.

— The *Sanitary Engineer*, commenting on the difficulty of providing a proper water-supply for the large cities, says that New York, for instance, requires for the needs of its population the entire available rainfall over two hundred square miles of territory. The intrinsic difficulties of the subject are enhanced by the fact that the supervision of these gigantic works depends more or less directly upon municipal boards which are made up on no basis of scientific or business qualification but merely from political availability. For general inefficiency the *Engineer* awards the palm to Philadelphia, with New York a close second, and give to Boston the third place.

— It is claimed by a writer in the *Répertoire de Pharmacie* that linseed meal which has been deprived of its oil is superior to the ordinary ground seed for the making of poultices for the reason that the oil if present is so imprisoned by mucilaginous matter on the addition of warm water to the meal that it does not have any unctuous action on the skin, not even greasing the cloth; but that, on the contrary, by becoming rancid, it interferes with the proper soothing action of the poultice. So that when the oil has been removed the meal makes a lighter poultice and one less liable to cause unpleasant results than one made of the oily meal.

NEW YORK.

— There having occurred some unpleasant dissensions in the Medico-Legal Society, a new association, having for its object "the advancement and study of medical jurisprudence, and the attainment of a higher standard of expert testimony," was formed last month of a number of prominent members of the old Society not "in harmony" with its present management, as well as others of the medical and legal professions. The first meeting of the new body, which is called the New York Society of Medical Jurisprudence, was held at the Academy of Medicine on Thursday evening, January 11th, when the following officers were installed: President, George P. Avery, Esq.; Vice-President, J. S. Wight, M. D.; Secretary, N. E. Brill, M. D.; Financial Secretary, S. B. Livingstone, Esq.; Corresponding Secretary, J. F. Chauveau, M. D.; Treasurer, E. C. Harwood, M. D.; Trustees, Drs. T. C. Finnell, A. M. Jacobus, and C. S. Wood, and Messrs. George P. Avery, A. J. Delaney, and Max F. Eller. Prof. J. S. Wight, M. D., of Brooklyn, read a paper on the bearing of illusions and hallucinations on testimony, in which he gave a number of instances in which witnesses had testified in regard to things which they believed had actually occurred, but which had not done so in fact. The paper was discussed by Drs. Hammond, Spitzka, and others. The second paper of the evening consisted of a report of the case of Margaret Keppel, the Brooklyn child abductor, by Dr. Landon Carter Gray. In May last the writer was called to examine a woman, charged with stealing a small towel from her employer, as to her soundness of mind. He became convinced of her insanity, and she was acquitted on this ground. This was the same woman who, in August, startled the community by her abduction of a little girl in Brooklyn, and Dr. Gray gave many interesting details of her case, which he had had an opportunity of studying in jail since that event, and which had become considerably aggravated since his first examination in the spring. The new Society has a membership of over one hundred, and among the more prominent medical men interested in it are Drs. Meredith Clymer, J. S. Wight, Clinton Wagner, T. A. McBride, T. E. Satterthwaite, W. A. Hammond, Nathan Bozeman, T. C. Finnell, and C. S. Wood.

— Dr. John T. Nagle, registrar of vital statistics, has completed his statistical tables for the year 1882. During the year the actual mortality was 37,924, or 29.64 per 1000, in an estimated population of 1,279,560. Of deaths at the age of one hundred and upwards there were 13, between ninety-five and one hundred, 34, and between ninety and ninety-five, 61. The largest mortality in adult life was between the ages of thirty-five and forty years, namely, 1916. Under the age of five years there were 17,520 deaths, and of these 9867 were of children under one year. In 1881 the deaths of children under five years of age numbered 17,737. The total mortality in public institutions was 7449 against 7146 in 1881. The deaths from diarrhœal diseases were 4050; from scarlatina, 2066; from diphtheria, 1525; from measles, 913; from croup, 729; from whooping-cough, 658; from malarial fever, 540; from typhoid fever, 326; from smallpox, 259; from cerebro-spinal fever, 238; from typhus fever, 65; and from puerperal fever, 59.

— Although the mayor, in his message of January 1st, stated that there were no cases of typhus at that time in New York, so far as known, it seems that there were two or three cases of the disease in a tenement house in the eastern district of the city, which were mistaken by the physician in attendance for typhoid. Since then one of the patients has died, when

the autopsy, ordered by the health authorities, showed distinct evidences of typhus, and several new cases have developed. All the patients, with the exception of one, who was too ill to be moved, have now been taken to the hospital, and the premises have been thoroughly disinfected and fumigated. As strict a quarantine as possible is maintained in regard to the case still remaining at the house, which will also be removed to the Riverside Hospital at as early a date as practicable.

Miscellany.

A CASE OF MULTIPLE MALFORMATIONS.

THE *Glasgow Medical Journal*, January, 1883, reports an unusual case of complicated malformations in a child of healthy parents, who had had two well formed children. The infant in question, however, presented a large tumor connected with spina bifida, extreme talipes varus of both feet, absence of anus, scrotum, and of skin from the penis. In spite of these deformities the child lived several days. During this time the fæces were voided through the penis, and were not unusual in appearance. The penis was exposed to its root, where the skin was reflected on to the scrotum. The parts uncovered by skin were red, and exuded blood. There was no glans penis, and of course no prepuce, and the pendulous tip of the organ was curved around so that the urethral orifice looked backward. At birth the tip was black, suggesting a gangrenous process, but the blackness wore off, so that it was attributed merely to the action of meconium.

The child urinated, and though at first it was difficult to say whence the urine issued, and impossible to define exactly the urinary tract, the water was afterward observed to trickle down from a furrow or fold of the perineal skin, below, or posterior to, the root of the penis. It came from some opening or aperture so diminutive as to escape observation, about half an inch above, or anterior to, the normal situation of the anus. It trickled downwards perplexingly, totally deficient of that force which could cause a stream, and indicate the aperture. The urinary tract seemed quite disconnected with the penis, from which latter no urine was at any time observed to escape.

The urinary and fæcal apertures of exit were thus reversed as to position and organ, the structure which develops into the anal aperture in ordinary cases being solely the urinary aperture in this case, and that which is normally the urinary exit canal being here the only anal aperture, or at least the only channel whence the fæces escaped.

Above the pubes was an irregularly triangular space devoid of skin, terminated above by a crescentic border. This undoubtedly represented the bladder, which was covered with a thin abdominal wall, to be sure, but evidently showed an approach to the condition known as exstrophy. The navel, however, was present, and no urine exuded above the pubes.

The child died with symptoms which indicated that the immediate cause of death was connected with the cerebro-spinal tumor, though of course the imperfect exit for the fæces would have soon become a peril to life.

PAGET'S DISEASE OF THE NIPPLE.

DR. T. MCCALL ANDERSON, in the *Glasgow Medical Journal*, takes the ground (in opposition to Sir James Paget) that this disease is essentially of malignant nature from the first, and not a mere eczema which by constant irritation has developed a cancerous growth. He does not deny that such a connection may occasionally occur, just as syphilitic disease of the tongue may in time lead to cancer of that organ; but believes, with Dr. Thin, that Paget's disease is from the first demonstrable microscopically as "a slowly advancing cancerous change near the mouths of the lactiferous ducts, which at a very early stage leads to irritative effects in the superficial tissues of the nipple and surrounding skin, and eventually penetrates into the substance of the mammary gland." If this be true it is of course of great importance to discriminate from the beginning this disease from an eczema. The diagnostic points on which he relies are as follows:—

PAGET'S DISEASE OF THE NIPPLE.	ECZEMA OF THE NIPPLE AND AREOLA.
(1.) Occurs especially in women who have passed the grand climacteric.	(1.) Occurs especially in women earlier in life, and particularly during lactation, or in persons laboring under scabies.
(2.) Affected surface, in typical cases, of brilliant red color, raw and granular looking after the removal of crusts.	(2.) Surface not so red and raw looking, and not granular, but often punctated.
(3.) When grasped between the thumb and forefinger, superficial induration often felt, as if a penny were laid on a soft elastic surface and grasped through a piece of cloth. (Thin.)	(3.) Soft, and no induration.
(4.) Edge of eruption abrupt and sharply cut, and often elevated.	(4.) Edge not so abrupt, and not elevated.
(5.) Very obstinate, and only yields to extirpation or other treatment applicable to epithelioma generally.	(5.) Although sometimes obstinate, yields to treatment applicable to eczema.

SYPHILITIC INOCULATION AT ALGIERS.

THE *London Times*, November 9, 1882, gives an account of the deplorable results of vaccination with contaminated humanized virus among the military garrison at Algiers. The vaccination was ordered in accordance with the sanitary regulations. Two army surgeons operated. The vaccine matter was extracted from a couple of children under two months old, apparently in excellent health, and in whom the lymph appeared to be equally genuine and normal. Those vaccinated from one of the children presented no special incident, but the fifty-eight soldiers vaccinated from the Spanish infant developed in a few weeks the characteristics of an infection which could not be mistaken, — all were attacked with syphilis. The marks on the arm were troublesome, and the ulcerations were so threatening that the soldiers were, some ten weeks after the operation, sent to hospital. In a month all except six were dismissed, but they were soon compelled to return. The usual train of constitutional symptoms followed, as appears from the article, in every case where the individual had been vaccinated from the infected child.

THE SUBCUTANEOUS USE OF ETHER IN HÆMORRHAGE.

To see if injections of ether have any utility in exhausting hæmorrhages, M. Hayem[1] has been making experiments. He finds that when the hæmorrhage

[1] Journal de Médicine de Paris, 23 Decembre, 1882.

becomes grave there follow transient clonic movements, with some stiffness of the legs. The withdrawal of an amount of blood equal to one nineteenth of the body weight of dogs was always fatal, the only difference being in the number of minutes or hours elapsing before death.

A bleeding to the extent of one twentieth of the body weight was, however, recovered from in the case of most of the animals. Injections of ether had no noticeable effect in the dogs which had been bled to one nineteenth, with the exception of causing an excitation in the beat of the heart, but injection of defibrinated blood or serum prevented a fatal result in several cases.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 13, 1883.

[1] Twenty-two deaths by hotel fire not included.

Deaths reported 2721 (no reports from St. Louis and Buffalo): under five years of age 863: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 579, consumption 386, lung diseases 368, diphtheria and croup 188, small-pox 113, scarlet fever 79, typhoid fever 56, diarrhœal diseases 39, whooping-cough 30, measles 29, malarial fevers 22, erysipelas 12, puerperal fever seven, cerebro-spinal meningitis four. From *typhoid fever*, Philadelphia 15, Pittsburg nine, Chicago five, Baltimore and Cincinnati four each, New York and Boston three each, New Orleans two, Brooklyn, District of Columbia, Providence, New Haven, Charleston, Nashville, Cambridge, Lawrence, Holyoke, and Gloucester one each. From *diarrhœal diseases*, New York 12, New Orleans seven, New Haven five, Brooklyn four, Boston and Baltimore three each, Chicago two, Cincinnati, Pittsburg, and Providence one each. From *whooping-cough*, New York nine, Cincinnati five, Chicago four, Pittsburg three, Brooklyn, Baltimore, and New Haven two each, Philadelphia, District of Columbia, and Milwaukee one each. From *measles*, New York 16, Philadelphia and Cincinnati three each, Lynn two, Boston, Baltimore, New Haven, Salem, and Holyoke one each. From *malarial fevers*, Brooklyn seven, New York six, Baltimore four, District of Columbia three, New Orleans two. From *erysipelas*, Baltimore four, New York three, Somerville two, Brooklyn, Boston, and Milwaukee one each. From *puerperal fever*, New York, Boston, Baltimore, Cincinnati, New Orleans, Pittsburg, and Somerville one each. From *cerebro-spinal meningitis*, New York, Philadelphia, Worcester, and Lawrence one each.

Two hundred and fifty-six cases of small-pox were reported in Baltimore; diphtheria 43, scarlet fever 22, typhoid fever eight, in Boston.

In 31 cities and towns of Massachusetts, with a population of 903,441 (population of the State 1,783,086), the total death-rate for the week was 21.58 against 19.84 and 23.36, for the previous two weeks.

The meteorological record for the week ending January 6th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

OBITUARY. WALTER BURNHAM, M. D.

WALTER BURNHAM, M. D., died in Lowell, January 16, 1883, after an illness of five weeks, the exciting cause of death being gastritis.

He was born in Brookfield, Vt., January 12, 1808, being the son of Dr. Walter Burnham. He studied medicine with his father and with his brother, Dr. Z. P. Burnham, a pupil of Dr. Nathan Smith. He graduated from the Medical Department of the University of Vermont in 1829, and, after practicing in several places, settled, in 1833, in Barre, Vt., where he lived until his removal to Lowell, Mass., in 1846. For several years previous to this change he was treasurer of the Vermont State Medical Society. While living in Vermont he made many difficult surgical operations, laying the foundation of a reputation as a surgeon which extended throughout the United States and into Europe. But it was after his removal to Massachusetts that the work to which he devoted so much time and in which he so excelled was begun, — that of gynæcological surgery.

As an ovariotomist he was among the early advocates of the operation. His first case of removal of an ovarian tumor was in August, 1851, his last in March, 1882. During this period of thirty-one years he operated on about three hundred cases. The number is believed to exceed this, but the exact figures are not at present attainable. The per cent. of success is above seventy-five.

His first case of ablation of the uterus and its appendages, for fibroma of the uterus, was operated upon in June, 1853, and was the first successful case on record. The woman is still alive. He made this operation fifteen times, having three successes. His experience with these led him to doubt the propriety of the operation, save in selected cases.

As a general surgeon he was well known. Among his successful cases were two of ligation of the common carotid artery, and one single case in which, having a short time before ligated the right external carotid he ligated the left external carotid for a malignant tumor of the jaw, the growth being much retarded.

Among the services for which the profession in Massachusetts are indebted to him was the passage of the Anatomy Act, the bill of which he as a member presented to the House in 1855, and was influential in having passed. By it medical men were authorized to obtain the bodies of dead paupers for dissecting purposes. He was a member of the American and State Medical Associations and honorary member of various State Societies. He was also surgeon of the Sixth Massachusetts Regiment from 1862 until his resignation about 1870.

As a man, honorable and outspoken in his opinions; as a practitioner, of extensive research and careful observation, and of boundless charity to the poor seeking his aid, from whom it was never withheld; he was kindness itself to students and to men young in the profession, to many of whom, his former pupils, now distinguished men, knowing his great heart, the news of his death will come with a sense of personal loss.

MEDICUS.

APPOINTMENTS. — Dr. George H. Bixby has been appointed one of the physicians to the Out-Patient Department for Diseases of Women at the Boston City Hospital, in place of Dr. Chadwick, resigned.

William A. Dunn, M. D., has been appointed surgeon to Out-Patients at the Carney Hospital.

COMMITTEES ON PUBLIC HEALTH, WATER SUPPLY, AND DRAINAGE, OF THE MASSACHUSETTS LEGISLATURE.

THINKING it may prove of interest to our Massachusetts readers, we print the names of the members of the Legislature appointed on the above committees: —

Committee on Public Health.

SENATE.

Water R. Mason, of Middlesex.
James O. Parker, of Essex.
Dexter B. Hitchcock, of Hampden.

HOUSE.

Horace L. Bowker, of Boston.
David L. Ambrose, of West Newbury.
Frank W. Adams of Royalston.
I. Dwight Stowe, of Fall River.
Charles L. Randall, of Boston.
Henry B. Martin, of Milton.
Charles W. Donahoe, of Boston.
Alonzo J. Stetson, of Danvers.

Committee on Water Supply and Drainage.

SENATE.

James S. Allen, of Plymouth.
Henry J. Wells, of Middlesex.
James A. McGeough, of Suffolk.

HOUSE.

Benjamin F. Campbell, of Boston.
Charles Smith, of Andover.
Warren A. Bird, of Natick.
Arthur F. Whitin, of Northbridge.
William H. Sayward, of Boston.
John McLaughlin, of Boston.
Joshua T. Foster, of Medford.
Chester W. Kingsley, of Cambridge.

MIDDLESEX NORTH DISTRICT MEDICAL SOCIETY. — The quarterly meeting of the Middlesex North District Medical Society will be held at the St. Charles Hotel in Lowell, Wednesday, the 31st inst., at four o'clock P. M. A paper prepared by Dr. William H. Lathrop, of Tewksbury, on Incipient Mental Disease, will be read by the author. A paper on Typhoid Fever, its Causes and Treatment (not on Venesection, as previously announced) will be read by its author, Dr. Harvey Knight, of Lowell.

GEORGE C. OSGOOD, *Secretary.*

APPOINTMENTS OF TRUSTEES IN THE MASSACHUSETTS LUNATIC HOSPITALS. — Governor Butler has made the following nominations to the position of trustee in the State Lunatic Hospitals: Simeon Borden, of Fall River, reappointed, at Taunton; William Dickinson, of Worcester, in place of Rev. Mr. Moors, whose term has expired, at Worcester; John Bancroft, of Reading, in place of Dr. C. F. Folsom, whose term has expired, at Danvers.

Original Articles.

CASES OF INTESTINAL OBSTRUCTION TREATED BY MEANS OF THE RECTAL TUBE.[1]

BY J. FOSTER BUSH, M. D. (HARV.)

Case I. G. W., a detective policeman, was first seen by me February 21, 1882. He was suffering from abdominal pains, irregular in character, but severe. The abdomen was hard and tender to touch. Upon questioning, I found that he was habitually constipated and had not had a dejection for two days, and that on the night before he had indulged in a lunch of beer and cheese before retiring, and that a few hours after he was awakened by abdominal pain.

He applied hot poultices, took two large doses of tinct. rhei comp., followed by pulv. glycyrrhizæ comp. The pains increasing, he took, upon the recommendation of an apothecary's clerk, pulv. ipecac. comp. grs. x., following it up with Rochelle salts and Tarrant's seltzer aperient.

When I saw him he had experienced some nausea, but had not vomited, and he complained of feeling cold in his bowels.

I ordered a large rectal injection, turpentine stupes to the abdomen, a tablespoonful of "Warburg's tincture" in warm water, to be followed by liq. morphiæ sulphatis, one drachm every half hour till he obtained relief. Four hours later I again saw him. He was experiencing excruciating pains, abdomen tympanitic and generally tender, and a particularly sensitive indurated mass was found in the region of the transverse colon on the left side. Another large rectal injection was given without obtaining relief, therefore I administered morphia, giving within an hour and a half three subcutaneous injections of half a grain each, after which he was free from pain, but did not obtain sleep.

On February 22d I found him with a high pulse and temperature, tender and tympanitic abdomen, and a recurrence of the pain. Vomiting was a constant symptom, and the tongue was brown and dry. There was mild delirium. A dose of castor oil combined with opium was given, to be followed by a large rectal injection of molasses, olive oil, turpentine, and soapsuds; the hips to be raised on an inclined plane while the injection was being given. The pain and vomiting increased, and the injection came away clear.

The only sustenance given was cracked ice and clear coffee in small quantities often, which was well borne.

There was retention of urine, which required the use of the catheter. Hot flax-seed poultices were applied to the abdomen, and three quarters of a grain of sulphate of morphia was given subcutaneously.

On February 23d he felt comfortable, and there was reduction in both pulse and temperature. There were constant eructations, but no vomiting. The abdomen was less tympanitic, and on deep pressure gurgling could be felt. The only tenderness was in the neighborhood of the induration previously spoken of. Only one subcutaneous injection of a quarter of a grain of morphia was necessary.

The next day, February 24th, Dr. H. H. A. Beach saw the patient in consultation, and coincided in the opinion that continuation of the rectal injections was the best course to pursue, large quantities to be given, and in order to have it reach as near the spot as possible he recommended that a rectal tube should be used, that morphia enough to quiet pain was to be given.

I obtained one of the Davidson Manufacturing Company's red-rubber stomach tubes twenty inches long, the exterior of which is as smooth as glass. This I introduced its full length, the patient lying upon his left side, and threw into the colon a large injection, which, when it came out, was found to contain fæcal matter with a highly disagreeable odor.

On the 25th there was less constitutional disturbance. Two injections were given through the tube, each of which brought away fæcal matter, but only in small quantities. His nourishment consisted of Valentine's beef juice in small quantities, often, homemade beef tea, and clear coffee. He experienced no pain except over the colon, the stomach doing its duty well, and there being little tympanites. Half an ounce of sulphate of magnesia, with half a grain of socotrine aloes, was given in equal parts of syrup of ginger and peppermint water.

On the 26th Dr. Beach again saw the patient in consultation, and advised a continuance of the injections, and a repetition of the salts combined with aloes. The only objection to the tube used was that the holes being on the side the flow of the injected water was obstructed; therefore we tried a piece of the common white tubing open at both ends. This was introduced twenty-four inches, and an injection given, but the exterior of the tube was rough in comparison to the red, and caused so much pain that we had to discontinue its use. Two injections were given on this day with the same results as on the day before.

The 27th found him in the same condition, save that he voided his urine voluntarily, the use of the catheter having been necessary till this time.

Early on the morning of the 28th I had given him another dose of the salts and aloes, to be followed in two hours by an injection given as usual. Upon the return of the injected water white particles resembling cheese were noticed, and also a substance which I did not see, but which, according to the statement of the patient's wife, must have been mucus, as it "looked like jelly." As the patient thought he felt wind pass through the bowels, ol. ricini, in teaspoonful doses, was ordered to be given every three hours unless nausea or pain was produced; only one dose was given, however, as the patient felt distressed from it.

On March 1st Dr. Beach again saw him. The constitutional symptoms were good. He had no pain. In the sediment from the injections fæcal matter and mucus were found, and floating on top of the water were fat globules, and as no oil had been given per rectum for a number of days it was thought that the particles seen might have come from the oil administered the day before. It was decided to continue the injections, using glycerine and water, and to give per ora

℞	Ol. ricini	ʒi.
	Glycerinæ	ʒij.
	Tinct. opii comp.	ʒi. M.

every three hours, unless gastric disturbance or abdominal pain was created. The injection of the glycerine was followed by tenesmus. Four doses of the mixture were given before inducing any action, but the fifth was followed by expulsion of flatus, followed by a dejection, which was shortly followed by a second, of watery character, with mucus and pus, and small hard masses, in one of which was the presence of a sub-

[1] Read before the Boston Society for Medical Observation, November 20, 1882.

stance resembling potato, very smooth on one side and rough and irregular on the other, as if it had been detached from the outside of a mass. This fæcal matter was the first of any distinct form passed.

On March 2d more fæcal lumps passed. There was no pain, but there was local tenderness at times. From this time onward recovery was rapid.

The highest pulse was 120, and the highest temperature shown by the thermometer was 103.4° F.

CASE II. J. R., an American, aged thirty, had always enjoyed good health, but was habitually constipated. On September 14, 1882, he ate heartily of corned beef and cabbage. That night he was taken with abdominal pain, which was referred to the region of the ascending colon. He took a dose of castor oil, followed it up with rhubarb, and later on took laudanum, without experiencing any benefit.

On September 16th I saw him. The pain was intense, the abdomen was tympanitic and tender, and there was vomiting whenever any food was taken. The temperature was 102° F., the pulse 120, and the tongue dry. I gave half a grain of the sulphate of morphia subcutaneously, ordered fomentations to the abdomen, and directed that a large rectal injection of warm water should be given, and morphia enough, in the form of suppositories, to relieve pain.

On September 17th there was delirium, the abdomen was greatly distended, the temperature 104.2° F., the pulse 140, and the tongue brown and dry. Vomiting was frequent and eructation was constant. Retention of urine required the use of the catheter.

The injection of the day before having come away clear, I introduced the long Davidson tube, as mentioned in the previous case, and injected about three quarts of hot soap-soads. Hard, dry fæcal masses came away with a return of the injection, but the pain and tympanites were not relieved. Vomiting still continued. I gave a subcutaneous injection of half a grain of the sulphate of morphia, and ordered the suppositories to be continued *p. r. n.*, and gave cracked ice and clear coffee for nourishment. The pulse and temperature still remained high.

On September 18th I gave through the tube another large rectal injection of soap-suds, sweet oil, and molasses. The fluid upon its return contained fæcal masses similar to those of the day before. Flatus escaped soon after, and the intense pain subsided, though general tenderness continued. I gave a mixture containing

R Magnesiæ sulphat	℥ ss.
Syr. zingerberis	℥ i.
Aq. ment. pip.	℥ ss.
Aq.	āā ℥ iv.

to insure complete evacuation of the bowels, and directed that a teaspoonful of the compound licorice powder be taken every night.

A week later the patient had a sharp attack of pleuritis, which confined him to the house for a time, but there had been no return of the abdominal pain or constipation, the powder producing a good effect.

CASE III. J. R., on Sunday, September 24, 1882, went out into the country for a day's pleasure, and while there ate largely of "choke cherries."

On September 26th he was unable to perform his work, that of a mason, on account of abdominal pain, for which he took fluid extract of senna and castor oil. When I saw him he located the pain as being on the right side of the abdomen and extending along the line of the colon. Local pressure produced pain, but no induration was found. There was no elevation of the temperature and no vomiting. I gave a saline cathartic combined with twenty drops of laudanum. Four hours later I found him in great pain, the extremities were cold, and the abdomen was tympanitic and exquisitely tender, the slightest pressure producing pain. There was vomiting. A half a grain of the sulphate of morphia, given subcutaneously, relieved the pain; fomentations to the abdomen were employed, and a rectal injection of laudanum and starch was to be given every three hours if there was a recurrence of the pain. Coffee and ice, as in the other cases, was the only food given.

On September 27th I gave through the tube a large rectal injection, which came away without fæcal matter. There was less tympanites and pain, but there was stercoraceous vomiting, and retention of urine, though the pulse and temperature were not much above normal. A second rectal injection was given, with a like negative result.

On September 28th his condition was unchanged; the pain and tympanites were not great, but the vomiting was still fæcal in character and quite fetid. The patient felt flatus descend to a certain point and then stop; he declared that it was at the entrance of the rectum, but such was not the case. A large rectal injection was given, the tube being used, but the fluid did not return for some time, and when it did it was very offensive.

On September 29th a large rectal injection was again given, and this time dark, hard, fæcal balls were expelled. They were covered with bloody mucus. Flatus escaped, at first in small quantities, the patient saying it seemed as if it came through a pin-hole. The patient having had a strong craving all day for beer, a glass of it was given, and it acted as a mild purge.

On September 30th a saline cathartic was administered. Since then there has been no trouble.

It will be noticed that in the first and third cases the exhibition of cathartics was followed by an exacerbation of pain and discomfort, yet none of this class of drugs were administered till the inflammatory symptoms had apparently subsided.

Remarks. — These cases are reported to show the use of the rectal tube, by which means the fluids injected can be carried well up the bowels and brought near the disease; and one who has not tried this means can form no idea of the ease with which the tube is introduced, the patient often not feeling its introduction.

In two of these cases the patients asked me, after the tube was introduced, not to hurt them, they not having felt its passage beyond the sphincter ani.

Exactly how far an injection may be made to penetrate has for a long time been under discussion. From some experiments performed on the cadaver it was shown that water could be made to pass beyond the ileo-cœcal valve. Others claim that though in death the fluid may be made to penetrate beyond this point, yet in the living subject under normal conditions the tonicity of the valves prevents the passage beyond to the small intestine. Upon this subject Leichtenstein, in Ziemssen, says: "If we wish to act directly with enemata upon incarcerations or invaginations in the lower part of the ilium it is advisable to relax the ileo-cœcal sphincter by chloroform narcosis or by large doses of opium, so as to open the way for the injected

water to reach the point of occlusion. But not only under these circumstances, but also when we wish to reduce a twist, knot, or invagination of the colon by enemata, it is advisable, for more than one reason, to aid the operation by previously bringing the patient under the influence of opium." Concerning the penetration of fluids beyond the cœcum a recent writer on rectal alimentation mentioned the case of a patient who had taken no nourishment by the mouth for some time, who lived on rectal injections of beef tea, and in whose vomitus particles of beef tea were found.

These cases tend to show to what extent the intestinal canal can be distended without injury either to the structure or functions.

In order that the injection may do the most good possible the patient must bear patiently with a little discomfort, for it is as much the hyperdistention of the parts as the solvent action of the water that causes relief.

In the cases reported numerous injections were given, but one was never repeated till the patient had recovered from the unpleasant effects of its predecessor.

In the first case mentioned the only time the injections were suspended for any length of time was when pain and intestinal spasm had been created, and whenever this is done, or whenever we have fear that the intestinal structures have been weakened by inflammation or ulceration, of course the injections would be contraindicated.

Distention from below is not a new method, and other means than fluids have been employed. Air, for instance, has been forced in by means of a pump or bellows, or by chemical action, as by the injection of an alkaline followed by an acid solution. These last have only to be mentioned to be discarded, for they have not the soothing or relaxing properties of the water, which also exerts a force directly proportionate to the bulk employed, by reason of its compressibility and by its being regulated at will.

OBSERVATIONS ON THE MANAGEMENT OF ENTERIC FEVER ACCORDING TO A PLAN BASED UPON THE SO-CALLED SPECIFIC TREATMENT.[1]

BY JAMES C. WILSON, M. D.,

Physician to the Jefferson Medical College Hospital, and to the Philadelphia Hospital.

I DESIRE to lay before the college a plan of managing enteric fever, which I have employed during the past year, and which, tested by such uncertain but not necessarily fallacious means as are available for a limited series of cases, has yielded satisfactory results.

The object of this communication will, I believe, be best attained by first sketching in outline the plan of treatment itself, next by reviewing the considerations which led to its adoption, and finally by a brief study of the cases. This arrangement of the topics will enable us to economize time.

The Plan of Treatment. — The scope of this paper and the necessity to be brief debar me from the consideration of the general management of the patient, dietetics, the treatment of complications and sequels, and of the prophylaxis, and restrict me, in the main, to the subject of the management by medicinal means. It is, in fact, this part of the treatment that, superadded to the so-called rational and expectant method in general use in this community, differs from the common practice, and constitutes the plan in question.

So soon as the patient is found to have enteric fever, or, in many instances, so soon as his symptoms warrant a reasonable suspicion that he is about to develop it, he is put to bed, ordered a diet consisting of milk, animal broths, jelly, and simple custards, in small amounts, and at intervals of two or three hours. At night he is given a dose of calomel. This dose varies in amount from seven and one half to ten grains (0.5 to 0.66 gramme), and is repeated every second evening until three, or, rarely, four doses have been administered in the course of the first six or eight days. It is given alone or in connection with sodium bicarbonate. There is commonly a slight increase of diarrhœa, if it be present, without aggravation of the other symptoms, and in some instances the tendency of the temperature at this time to steadily rise appears to be controlled. If, as is frequently the case, spontaneous diarrhœa has not recurred in the first week, the calomel usually brings about two or three large evacuations on the day following its administration, not more. In either case the tendency to frequent passages in the later stages of the attack is favorably influenced by the repeated administration of this drug during the first week. If the case does not come under observation until after the tenth day, one only or at most two doses of calomel are given. No further doses of it are, however, given during the course of the attack unless constipation occur. In this event, if the evidences of extensive or deep implication of the intestinal wall, such as abdominal pain, tenderness, or marked tympany, are absent, calomel in seven and one half grain (0.5 gramme) doses is given at intervals of three or four days. If there is reason to suspect serious intestinal lesions the lower bowel may be more safely emptied of its contents every third or fourth day by enemata of moderate size (eight to ten fluid ounces). It is necessary to bear in mind that the gravest lesion of the gut, leading even to hæmorrhage and perforation, have occasionally been observed in cases characterized not only by constipation but also by an entire absence of pain or tenderness, and very moderate tympany. The danger of salivation from calomel in these doses in enteric fever appears to be slight. In only one case in sixteen were the mercurial fetor and slight swelling of the gums observed.

Excessive diarrhœa has been controlled by the use of opium, either in suppositories containing one grain (0.06 gramme) or by the mouth in quarter grain (0.016 gramme) doses, often associated with bismuth and given *pro re nata*. It is an invariable rule that the patient be kept in the horizontal position, and to the use of the bed-pan and urinal from the time of the recognition of the disease until defervescence is completed. He is, however, turned upon his side from time to time, and made to maintain that position for twenty or thirty minutes, if necessary, being supported by the nurse.

From the beginning of the attack the following mixture is regularly administered in doses of one, two, or even three drops in a sherry glassful of ice-water, after food, every two or three hours during the day and night: —

℞ Tinct. iodinii . . . . . f℥ij. 8.00 cc.
Acid. carbolici liq. . . . . f℥ss. 4.00 cc. M.

[1] Read January 3, 1883.

Unless some unusual circumstance occur to render a change necessary, this medicine is not suspended until the attack draws to a close. It is well borne by the stomach, and excites no repugnance on the part of patients. In one case only has it been necessary to omit the carbolic acid on account of the disgust occasioned by its odor.

Partly for the sake of its favorable influence upon the skin, and for the sake of cleanliness, partly because of its favorable though slight influence upon the temperature, the patient is to be sponged twice a day with equal parts of aromatic vinegar or alcohol and cold water. If it is more grateful to him this sponging may be done with tepid water, the evaporation of an extensive film of water, not below the temperature of his body, probably being not wholly without a refrigerating tendency.

When the evening axillary temperature reaches 104° F. (40° C.) quinine in massive doses, twenty-four to thirty grains (1.66 to 2.00 grammes) is given upon a falling temperature. I usually direct eight to ten grains to be given in solution at five, at half past five, and at SIX A. M. the following morning. Administered thus at the decline of the temperature in its diurnal revolution, these large doses of quinine depress it from 2.5° F. to 3.5° F. (1.4° C. to 1.8° C). After the lapse of forty-eight to seventy-two hours, if necessary, the dose may be repeated. If these doses be rejected by the stomach, — an unusual circumstance, — half the quantity of quinine may be administered hypodermically. For this purpose a citric acid solution is to be preferred. Since the adoption of the plan of treatment under consideration I have not encountered cases attended with such hyperpyrexia as has rendered attempts to control it by cold baths necessary or even advisable.

The minor nervous symptoms are best held in check by skillful nursing. For the relief of the headache of the first ten days absolute quietude, a dim light, etc., are often sufficient; occasionally the bromides alone or in combination with chloral are required. Later in the course of the disease chloral is unsafe. From the end of the first week the patient cannot be left unattended even for a few minutes without risk. Persons in whom delirium was only occasional and transient have, in many instances, destroyed themselves during the momentary absence of the nurse.

Alcohol is not often indicated prior to the beginning of the third week. It may, however, by reason of the habits of certain patients, be necessary throughout the attack. Although forming no essential part of the treatment, it is commonly administered in varying though usually small amounts towards the close of the sickness. Some patients do well without taking it at all. It is of course administered in accordance with well-understood indications upon the supervention of delirium, ataxic symptoms, and the evidences of failure of the forces of the circulation. The patients are carefully watched well into convalescence, and cautioned against too soon regarding themselves as restored to health. The dangers of the establishment of a focus of contagion are guarded against by the systematic, thorough disinfection of the stools immediately after they are voided.

The considerations which led me to adopt the plan of treatment indicated in the foregoing sketch are: —

(1.) A feeling of dissatisfaction regarding the expectant method of treating enteric fever. This feeling, vague at first, grew more definite and stronger with increasing clinical opportunities, and a fuller knowledge of the natural history of the disease, until it became a motive, impelling me to cast about for some different and more satisfactory plan. This feeling has been during the past decade a very general one in the profession in all parts of the world, as is attested by an almost endless succession of journal articles setting forth new plans of treatment, and the use of new drugs in the management of this, the most common and most important of the acute infectious diseases of the present epoch in medical history. Most of the plans thus suggested have lead to disappointment when tested by the fuller observations of the profession; many of them have failed to attract general attention, and some few are still *sub judice*. Their number and diversity bear witness to a wide-spread distrust of the once well-established expectant treatment. This distrust is, however, based upon something more tangible than a mere feeling of dissatisfaction. The statistics of all observers whose cases have been sufficiently numerous to be trustworthy show enteric fever to be, when treated by the expectant plan, a disease of high death-rate.

The percentage of fatal cases rarely falls below 15 per cent., and often exceeds 25 per cent., according to the hospital records of this country, Great Britain, and Continental Europe. Jaccoud, with a collection of 60,000 cases, observed a mortality of 20 per cent.; Murchison, in 27,051 cases, 17.45 per cent.; Liebermeister, in 1718 cases, at Basle, under an expectant plan, records 27.3 per cent. of deaths. But turning from broad generalizations to personal experience, who is there here that, many times elated by the happy issue of mild or average cases treated by the expectant plan, has not realized the sense of utter powerlessness attending it when he has stood face to face with cases in which *to do* rather than *to wait* has been necessary to save life.

(2.) Enteric fever is the very type of the general diseases, of affections *totius substantiæ*. The tissues are universally implicated in the morbid processes; no function of the body wholly escapes perturbation. For this reason plans of treatment suggested by the prominence of certain groups of symptoms, or by the known lesions of particular organs, even though of undoubted benefit as far as they go, are in theory unsatisfactory because they are directed in effect against conspicuous manifestations of the cause of the sickness rather than against the cause itself.

Whilst in actual practice the treatment by turpentine, by alcohol, by opium with lead, or the silver nitrate, or by agents capable of controlling the febrile movement, as quinine, digitalis, salicin, and the salicylates, even the cold-water treatment itself, although at times and in the hands of certain clinicians showing favorable results — all these have failed of general acceptance on the part of the profession.

(3.) The general character of the disease, the specific nature of its cause, the unsatisfactory results alike of an expectant and of a symptomatic plan of treatment, or rather of the two combined, have united to render the idea of a specific treatment, a true cure for enteric fever, a most attractive one, to stimulate thoughtful observers to renew again and again the disappointing search for it. To this idea may be traced the treatment by the mineral acids, by chlorine-water, by carbolic acid, by quinine alone, by quinine and digitalis, by iodine, by the potassium iodide, by calomel.

(4.) Not only is the conception of a specific treatment for specific diseases a most attractive one, and the attainment of such a treatment for enteric fever brought within the bounds of a reasonable hope by the analogy of syphilis and the malarial diseases, but the search after it with due caution and judgment has also the warrant of the very highest medical authority.

Passing by some earlier names, I refer to DaCosta, who has said: "It would be as illogical as absurd to suppose that we shall never possess the coveted means really to cure the continued fevers. Doubtless to the physicians of the time of Charles V. the radical and specific treatment of the malarial fevers appeared as hopeless and remote as the radical and specific treatment of the continued fevers appears to the scientific inquirer of our day."

I refer also to Liebermeister, who treating about eight hundred cases, part with calomel, part with iodine, had with the former drug a mortality of only 11.7 per cent., with the latter of 14.6 per cent. against 18.3 per cent. for cases treated without those remedies, but in other respects upon a similar plan.

Bartholow has also spoken in favorable terms of the treatment by iodine in combination with carbolic acid.

The treatment adopted is thus seen to consist of the use of the two remedies that are proved to exert a favorable influence upon the disease, iodine and calomel, with the addition of carbolic acid in minute amounts. I am aware that no positive conclusions as to the efficacy of particular plans of treatment can be deduced from a limited series of cases. I am also aware that few acute diseases show greater variations in intensity and in the percentage of mortality at different periods, and under different circumstances, than enteric fever. Nevertheless I have ventured to occupy your attention with this subject to-night because the results of the treatment encourage me to hope that its discussion in this way will lead to its trial on a more extended scale. That it amounts to a specific treatment in the narrow sense is not affirmed. It is tentative, provisional, but it is nevertheless to be regarded as a contribution to the subject of the specific treatment of enteric fever.

The *total number of cases treated* by this plan is sixteen; all recovered, one being now in the second week of convalescence.

Of these, eight were severe, the temperature reaching or exceeding 104° F. (40° C.).

Of these eight severe cases, one was characterized by uncontrollable vomiting in the third week. The patient retained no food taken by the mouth for five consecutive days.

One case was very irregular in its course, and was complicated by an obscure abdominal abscess which discharged by the bowel. The temperature in this case on two occasions attained 105° F. (40.5° C.). This case presented the characteristic eruption of enteric fever.

A third case was prolonged by a severe relapse.

Of the eight cases in which the observed temperature did not at any time attain 104° F. (40° C.), and which were therefore looked upon as medium or mild cases, one was complicated by crural phlebitis, and another by the occurrence of intestinal hæmorrhage.

The average duration of the eight severe cases was about thirty-one days; that of the eight mild and medium cases was about twenty-five days.

Of the whole number ten were treated in hospital, six in private practice. All from the time of their coming under observation were under my personal care.

In two cases the special plan of treatment was abandoned about the beginning of the third week on account of the supervention of unusual symptoms of great gravity. These related respectively to gastric irritability and an obscure abdominal abscess.

These sixteen cases are unfortunately not a consecutive series. During the year in which I have had the opportunity of observing them, two other cases of enteric fever have occurred in my hospital practice in which this plan of treatment was not employed. One was that of a man suffering from rheumatism, who, after a stay of several weeks in the wards, and in a bed near that occupied by a patient very ill of enteric fever, was observed to be febrile, and to have the typhoid eruption. This person, previously greatly reduced, was not regarded as a suitable subject for a special treatment, the efficacy of which was not yet established in my mind. The other was a man who, with an obscure history of a sickness of many weeks, and a very irregular temperature, developed the typhoid eruption, and within forty-eight hours had general peritonitis. These two fatal cases have, however, no bearing upon the result of the treatment.

In private practice several cases of mild, continued fever, of long duration were treated upon this plan during the past winter. I believe them to have been anomalous cases of enteric fever, but as the rose spots of that disease were absent, and their departure from the typical disease was wide, I have not included them in the above collection of cases treated. They all recovered.

The result of this plan of treatment has not only been satisfactory in respect of the recovery of all the cases treated, an accidental circumstance not liable to mislead persons familiar with the disease, but it has also been satisfactory in respect of the general course of the attack, and the appearance of the patient. These were in the main, despite the severe type of the disease in several of the cases and despite the occurrence of grave complications, favorable. I make this statement with due regard to the personal equation, and with no willingness to permit the observed fact to differ from the actual fact, for I desire any who may make trial of this plan to be more favorably impressed with the results of it than they have been impressed with my account of it.

After the reading of the preceding paper: —

Dr. George Hamilton spoke of the great importance of preventing hypostatic congestion by changing the position of the patient from time to time. This was one feature of the plan of treatment recommended some time ago by Dr. William Pepper, in typhoid fever, by which he obtained the unequaled result of ninety-eight per cent. of recoveries. He was not, however, at this time able to recall in detail the method of treatment.

Dr. J. T. Eskridge stated that the treatment to which Dr. Hamilton referred consisted in the administration of nitrate of silver, and was that which had been introduced by the late Dr. J. K. Mitchell some years ago.

Dr. Roberts Bartholow said that the plan of treatment of typhoid, advocated in the very interesting and able paper just read, is, as all present probably know, in part, the so-called "specific" method. The administration of calomel in full purgative doses dur-

ing the first week serves a double purpose: it has an effect on the range of temperature, and it acts on the typhoid germs present and multiplying in the intestinal canal. The use of iodine, — usually Lugol's solution, — throughout the disease, is also one mode of the specific treatment. By the use of this medicine it is attempted to prevent the multiplication of germs in the intestine, to check fermentation, and to maintain an antiseptic action in the blood.

Although the existence of typhoid germs has not been proved, it must be regarded as possible. Klein, a few years ago, announced the discovery of the specific organism of typhoid in the affected intestinal glands, but Creighton, of Cambridge, showed that the supposed germs were produced by the mode of preparation. This *fiasco* threw great discredit on the whole question of germs. Nevertheless, the course of treatment directed against supposed germs — the antiseptic method — has had a most favorable influence on the progress and mortality from typhoid. Whilst the specific plan has been advocated in Germany, the Montpellier school have brought forward carbolic acid as the remedy, and the success which has attended the use of this remedy has been really remarkable. Quite a different complexion has been put on the statistics of mortality since they began the use of carbolic acid. It is probable that the combination of carbolic acid and iodine gives better results than the use of either singly. According to my observation, this method of treatment diminishes the diarrhœa, lowers the fever, and renders the disease much less violent, consequently lessening the mortality. Dr. Wilson has, therefore, rendered us a real service by drawing attention anew to this plan of medication, and especially by supporting his position with valuable cases and statistics. Besides this use of medicines, Dr. Wilson's treatment contains many valuable suggestions and practical methods, which, no doubt, contribute materially to his success.

DR. J. M. DACOSTA spoke of the purgative treatment in enteric fever as that which had been tried in the French hospitals and for a time sanctioned by Louis. As regards calomel it was partly by its purgative action that it was supposed to be beneficial. In his hands the calomel treatment had not yielded favorable results. He had found carbolic acid useful in controlling diarrhœa and in lowering the temperature. He had also employed thymol in one half to one grain doses. He suggested the use of this remedy in the place of carbolic acid as more acceptable to the stomach.

DR. WILSON, in reply to the question of Dr. Hamilton, said that he considered it necessary to frequently change the position of the patient to prevent pulmonary hypostasis. He had intended to emphasize this point in his paper. He called attention to the fact that carbolic acid and like drugs probably exert a favorable influence upon the course of enteric fever by their power to stay the rapid decomposition of the intestinal contents, which, for lack of the antiseptic influence of the intestinal juices, the bile, etc., all of which are changed, is a secondary cause of irritation, diarrhœa, and tympany. Calomel also, he thought, probably exerted an indirect beneficial influence in the same direction.

— It is said that in Wisconsin any druggist, apothecary, or vender of medicine is liable to a fine of ten dollars and costs for every time he is convicted of refilling a prescription marked "No Duplicate."

A CASE OF ABSCESS DISCHARGING AT THE UMBILICUS IN AN INFANT.

BY C. W. STICKNEY, M. D., HOLDEN, MASS.

THE cases described by Dr. Nichols in the JOURNAL of October 26, 1882, of abscess discharging at the navel in puerperal women reminds me of a somewhat similar case occurring in a female child six months old, and which may be of interest in connection with those cited. When first called to the case, in April last, I found the child suffering evidently from gastro-intestinal derangement, manifested by vomiting of everything taken into the stomach, slight febrile disturbance, thirst, sleeplessness, and constipation. There was some tympanites, but at first no tenderness of the abdomen. The tongue was covered for the most part with a thick, soft, white fur. The child had been troubled more or less with constipation from birth, otherwise had been healthy. Suspecting intestinal obstruction, I administered castor oil, which, however, affected the bowels naturally, thus relieving anxiety in this direction. After two or three days I found on palpation a circular area of induration about three inches in diameter, having the umbilicus as its centre. The umbilicus seemed to rest in a cup-shaped depression in the surface of the tumor; the swelling and induration were accurately defined by an abrupt though somewhat rounded circumference. Very light percussion revealed dullness over the affected region; deep percussion was tympanitic like the rest of the abdomen. Hop-bags and cloths wrung out of hot water were applied to relieve discomfort. Soon, however, the umbilicus began to push forward as a rounded red tumor which soon showed distinct fluctuation. Suppuration being now certain, light poultices were applied, and on the sixth day the umbilical tumor ruptured and discharged a small quantity of healthy pus. Some relief of symptoms followed, but the circular tumor remained in the same condition. Poultices were continued in the hope of keeping up the discharge, so that eventually the abscess might thoroughly evacuate itself through the external opening, thus lessening the risk of rupture into the peritoneal cavity. Matters now progressed well; there was a constant, free discharge of pus, and the indurated mass was perceptibly softening. But on the morning of the ninth day, while straining to evacuate the bowels, the patient passed suddenly into a state of collapse, and never rallied. An autopsy was not permitted.

When asked for a diagnosis, I gave: Either abscess of the abdominal wall external to the peritonæum or localized suppurative peritonitis circumscribed by adhesions, death in either case being caused by rupture into the peritoneal cavity.

— A very serious epidemic of measles has visited Iceland during the past summer, of special interest because the island, owing to its isolated position, had for thirty-five years enjoyed immunity from the disease, so that few of the inhabitants had ever had it. The disease was introduced May 2, and by the end of June 1100 out of the 2700 inhabitants of Reykjavik were ill, and six to eight deaths occurred daily. The total number of deaths in that town was one hundred and fifty. The commonest causes of death were the complications, capillary bronchitis and catarrhal pneumonia.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

C. M. JONES, SECRETARY.

NOVEMBER 20, 1882. DR. MORRILL presided.

DR. J. F. BUSH read the regular paper on

CASES OF INTESTINAL OBSTRUCTION TREATED BY MEANS OF THE RECTAL TUBE.[1]

DR. BLAKE remarked that perhaps no subject coming under the physician's care presented so many perplexing conditions as intestinal obstruction. Those of the large intestine belonged to the more easily recognized variety, in which treatment was oftener followed by successful results. In obstruction of the small intestine the symptoms are more obscure, diagnosis difficult, and treatment unsatisfactory. In the cases of the latter variety coming under my care the most distressing symptom after the first few days was flatulent distention. This, however, can now be relieved as often as necessary by the use of the smallest-sized needle of an aspirator, pumping out the gas until the distention is completely relieved. Life can be prolonged for weeks and months in many cases by this procedure, and time gained for other treatment. I have but little faith in the efficacy of medical treatment, however, in obstructions of the small intestine. Formerly, and, indeed, until quite recently, there seems to have been a morbid dread of the peritonæum, and nothing was done surgically to attempt to relieve these cases after medical treatment fails. Now, however, when one of our own surgeons, Dr. John Homans, shows eighty-nine per cent. of recoveries in ovariotomy, and without selecting cases favorable for operation, a record which is an honor to American surgery, and to which we can justly point with pride, it would be a grave omission of duty on the part of the medical attendant to omit recommending and strongly urging that at least an exploratory operation should be done. We all know that peritoneal bands, twists, and adhesions do not soften, break down, or come to any favorable change, and we can readily see how little benefit can be hoped in such cases for successful treatment with causes like the above in existence. A good deal is said about the difficulty of finding the seat of the obstruction, but when we remember that the intestine is always distended *above* and always empty *below* the site of the obstruction, this difficulty, in skillful hands, cannot be very great. Certain it is that success not infrequently attends such operations, as the reported recoveries in the journals show, and even the standard works on surgery are beginning to urge early operations. We should remember that the *time* chosen should be as soon after a fair trial of medical treatment has failed as possible. We all realize the importance of early operation in other cases, and the same reasons exist to perhaps a greater degree in this grave lesion.

The rectal bougie in its present exceedingly flexible condition is a valuable aid in allowing us to distend the large intestine with fluid. I have seldom been able to introduce more than two quarts. In relation to pumping air into the rectum, I am inclined to believe that although it may prove of benefit occasionally it should be done very carefully. Forcible distention of an intestine which may have been the seat of old ulcerations or otherwise weakened by disease cannot be free from danger.

I should, perhaps, have alluded to a class of obstructions of a spasmodic character, but there are so many varieties that it would take too much time to particularize.

DR. GERRY said: My feeling in regard to surgical interference in cases of intestinal obstruction is that this is the last resort after a physician finds that he has one of the more dangerous forms, and after other well-known remedies have been used in vain. Mr. Allingham, of London, although an expert in operations of this nature, is extremely cautious before inflicting an artificial anus upon a patient, and he related to me a case in which it seemed imperative for him to operate, but he hesitated and bethought himself of electricity, which proved successful, although the case seemed an extreme one, before the contents of the fæcal tumor started to come away, the diagnosis pointing to a loop or band. I am personally very much in favor of aspirating the intestines, as described by Dr. Blake, where that distressing and dangerous symptom, *distention*, is present. In cases of obstruction very active cathartics should be used with great care, a view which Dr. Bowditch impressed on my mind some years ago. Injections properly administered are a safe remedy, and usually give relief. As regards operation, it seems to me that with our knowledge of abdominal surgery we can be reasonably sure of a good per cent. of success. The operation does not appear even to friends so dangerous as formerly. But if undertaken at all it should be performed early in the history of the case, before serious inflammatory conditions can arise.

DR. WEBBER said: I have no experience in obstruction high up in the intestine, but in cases of fæcal accumulation in the colon, where injections of soapsuds have been of little value, an injection of half or three fourths of a pint of sweet oil, followed some hours later by a watery injection, has been successful. Obstipation is often caused by the undue absorption of the intestinal fluids, making the fæces dry and hard. While at the outset an injection of water is quickly absorbed, one of oil remains to soften the fæcal masses, and thus renders the subsequent watery injection effectual in starting downwards the contents of the bowel. The absorbents of the colon above the rectum are not so numerous as in the rectum itself. Hence, if by the aid of the tube the fluids are carried higher up the bowel they will be absorbed to a less extent than if merely introduced into the rectum, and thereby become more effective.

DR. BUCKINGHAM said he had had the same results as Dr. Webber, obstinate constipation, not obstruction, yielding readily to an injection of oil after repeated injections of salt and water had completely failed.

Dr. Buckingham inquired further what proportion of cases are relieved by continued narcotism without other treatment. He had seen a case in which a large injection had not broken down the obstruction, but in which, after the patient was made comfortable with opium, the obstruction had gradually moved along the colon, old fæces being discharged, and tenderness remaining at the original site.

DR. BUSH said his patients had been kept comfortable with opium. The pain was relieved, and if the trouble in any case depended on pain or spasms he

[1] See page 97 of this number of the JOURNAL.

would expect continued narcotism to afford relief without resort to other measures.

DR. F. C. SHATTUCK said that Dr. Buckingham's question reminded him of a colored man who came to the hospital a few years ago complaining of frequent attacks of colicky pain attended by constipation and flatulence. When the bowels were free he was pretty comfortable and could do his work. After a course of iodide of potassium the urine was examined for lead with a negative result. He was then treated by laxatives, and under careful management his attacks were for a time somewhat mitigated in severity and frequency. Still the attacks recurred from time to time, and Dr. Shattuck saw him in several of them outside of the hospital. The attacks were now clearly due to obstruction of the bowels, and the relief afforded by the subcutaneous injection of morphia was most striking. Freedom from pain was followed after a longer or shorter interval by copious discharges from the bowel, followed by convalescence and another period of comparative health. The man came later under the care of a homœopathic physician, who, after a fatal attack of obstruction, secured an autopsy, and was kind enough to show Dr. Shattuck the specimen, — a stricture of the intestine. Death occurred nearly two years after his first appearance at the hospital.

DR. FITZ remarked that the recent investigations of Nothnagel threw light on the favorable influence of morphine in certain cases of intestinal obstruction with stercoraceous vomiting. This observer found that small doses of morphia checked the ascending contractions of the intestine induced by the application of soda, and it was not unlikely that a similar effect might result where a temporary internal cause of intestinal obstruction was the occasion of ascending contractions. With the cessation of the latter the possibility of an evacuation of the retained intestinal contents was favored.

With regard to Dr. Blake's advocacy of operative interference in cases of intestinal obstruction, attention was called to certain serious objections. Although the recent advances in abdominal surgery were unquestionably such as greatly diminished the risk of an incision through its walls, under ordinary circumstances the condition of the abdominal cavity in intestinal obstruction was extraordinary.

The difficulties of diagnosis during life are such that time is often an important element in an eliminative diagnosis. With the occurrence of the more severe forms of obstruction such serious complications are likely to occur in this time that the operation is rendered inefficient. In this connection reference is made to the rapid occurrence of gangrenous inflammation of the intestine in cases of intussusception or of strangulation of the intestine, however occasioned.

With the frequent impossibility of a correct diagnosis previous to the operation there is often great difficulty in ascertaining the cause of the obstruction after the abdominal cavity is opened. With all the opportunities offered at a post-mortem examination it is usually a matter of difficult and protracted manipulation and dissection to discover the cause of obstruction. This is largely due to the enormous distention of the intestines above the place of obstruction, the abdominal cavity being crowded with bulging and elastic coils of intestine tied down by the mesentery. The examination of the deeper parts is thus obscured, and the relation of the intestine to its surroundings is confused.

DR. BOLLES spoke of the difficulty of finding intestinal obstructions at a post mortem. Generally they are such that it would have been impossible to have discovered them by any ante-mortem operation. In one case which he had examined, after finding a fibrous band, a careful dissection was requisite in order to release the bowel, and in a second case where there was a twist of the small intestine it had to be picked out with the uttermost care before passage through could be secured. In either case operative interference would have been a failure for the difficulties involved. Surgeons are deterred from operating, not by dread of opening the abdomen, but by the obscurity of diagnosis.

THE NEW PHARMACOPŒIA.

DR. B. F. DAVENPORT brought up the subject of the new Pharmacopœia, and spoke as follows: —

I wish to call the attention of the Society to the appearance of the new revision of a work which I fear that we as physicians are not nearly as interested in as we ought to be. The new United States Pharmacopœia has now, after the continuous labors of the committee in its revision, ever since the meeting of the convention at Washington, D. C., in May, 1880, at last been published. It is now a far more important work than it has ever been before, both on account of its own scientific merits and because it has now been made by State statute the legal standard to which all official medicines are required to conform in regard to their strength, quality, or purity.

Among the more important changes that have been made in this upon the last revision are the following: —

The substitution in the formulas of parts by weight for specific weights and measures, in most cases without making a material change in the strength of the preparations, in the fluid extracts, however, the exception being made of having the finished product made up to a certain metric measure instead of weight, whereby they are decreased about five per cent. in their strength. The vinegar, wine, and tincture of opium are now all of a uniform ten per cent. opium strength. The first two being thus considerably decreased while the last is increased about ten per cent. in its strength.

Two hundred and fifty-six new titles have been added to the list, which, after the reduction made by the 229 omissions, left still 997 titles in the official list.

As we have now the best Pharmacopœia of any nation, we physicians have no excuse for the prescribing of proprietary medical preparations. As Prof. C. A. Lindsley, of Yale College, so justly argues in his able essay read before the Connecticut Medical Society, at its last annual meeting, the use of ready-made formulæ is demoralizing to the profession, because they are sure to lower the standard of professional intelligence, to diminish the accurate knowledge of materia medica and the capacity of making wise therapeutic adaptations of remedies.

What encouragement is there to pharmacists to become skillful and expert if the physicians make no demand upon them, but oblige them to send to a distance for preparations which they could make as well or better themselves. Any apprentice could pass over the counter and take the pay for ready-made preparations. The pharmacist thus defrauded of the exercise of his proper functions, the option of either making or of selection, according to his own best judg-

ment from the market, of all the pharmaceutical preparations which he is called upon to dispense, is degraded to the vocation of a mere shopkeeper, and is compelled to pay to the manufacturing pharmacist the profits which are justly his own. Then, too, he cannot be so justly held answerable for the quality of other men's preparations which are not of his own selection as he could if he was given his choice of himself preparing or of taking the preparations of others whom he felt willing to guarantee. In regard to the very serious evil to him of having to keep a full line of all the different makes of coated pills, fluid extracts, and elixirs, just ask your nearest apothecary and get a most feeling expression thereof, if you are in any doubt. Further than this indirect injury to ourselves done through the pharmacist there is the direct evil of providing at all the drug stores the very medicines we are ourselves accustomed to prescribe already done up in convenient packages, with wrappers with full printed instructions as to the diseases they will cure, and with all the requisite directions as to dose and administration. The druggist is of course just as familiar with them as is the physician, for both get all their information from the same source, that is, from the wrappers themselves. Why should the patient go to his physician when the druggist can show to him his own physician's published certificate upon the wrapper of his bottle that its contents is the best cure for the disease from which he now suffers?

GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FIELD, M. D., SECRETARY.

Stated Meeting, first Thursday in April, 1882.

President Wheeler in the chair.

THE OBLITERATION OF THE UTERINE CAVITY IN PREGNANCY.

Dr. H. R. Storer remarked he had been struck, during the reading of the records of the last meeting, with Dr. Norris's position in respect of the obliteration of the uterine cavity in pregnancy, procured by the turgescence of the glands, — a condition, it was commonly assumed, which might not be complete under three months. Would ask how complete placenta prævia can be explained consistently with this statement; would also remark the frequency with which, as it is claimed, the uterine sound can be passed up and swept about in the early months of pregnancy without occasioning abortion.

Dr. Marcy suggested discussion of these points should be delayed until his paper was read, as closely cognate matters were therein discussed.

Call was hereupon made for Dr. Marcy's paper, —

SOME FORMS OF DISEASE OF THE PLACENTA.

The reader remarked in a prefatory way that his subject was of necessity complex and concisely presented, but he had done the best he could to make himself clear. The paper was frequently illustrated by various diagrams.

He began by giving a careful review of the histogenesis of the placenta, showing the great value of comparative anatomy, and the light shed upon this important subject by its teachings, especially as developed by the studies of Owen, Huxley, Turner, and Ercolani. All the vertebrates, during the period of embryonic life, in order to complete the marvelous phases of their development, require special nourishment, which is always furnished them by the mother. This is conveyed to and converted into its own substance by the embryo, and however many and considerable may be the differences in these two fundamental factors, the unity running through them readily appears under two different forms, represented by the yolk of the egg in the oviparous animals, and by the placenta in vertebrate mammals. In the first the maternal aliment is stored up in a mass by the mother, surrounding the ovum in such quantity as is needed by the embryo to complete its development; in the second this nutrition is furnished by the mother through the placenta, which elaborates it as is needful for the developing embryo. These materials in every case are absorbed and conveyed to the fœtus by means of its own vascular appendages. This nutrition is carried on during the developing period in all vertebrates through a single law of physiological modality. The typical anatomical form in the two fundamental parts of the placenta, however wide the variation, is always identical: a villus of new formation both in the maternal and fœtal part, composed of an internal vascular loop, surrounded by protoplasmic cells, and covered by an outer epithelium. The office of the villi only is different, the fœtal being *absorptive*, the maternal villi *secretive*.

These villi always come in contact more or less intimately, but the walls of the vascular loops never in any instance touch. This is the more to be emphasized since it invalidates the idea hitherto held, and still almost universally taught, of the mode of the nutrition of the fœtus: interchange between the two bloods by endosmosis and exosmosis.

The different ways of interblending between the fœtal and maternal villi give the complex and confusing picture of placental formation. In the development of the single placenta the epithelial covering of the vascular loop of the fœtal villus is wanting, because of the intimate relation which has been established between it and the secretory villus, which *never* loses its own epithelial covering. The form of the vascular loop of the maternal villus is very greatly varied, and in the quadrumana and the human species the dilatations become lacunose and are actually enormous.

During the early period of pregnancy in woman the decidual cells form a complete layer, richly vascular, into which the villi of the chorion penetrate and ramify. For a time the relationship between these two parts is not so close that they cannot be separated. In this stage, before the maternal vessels become ectasic, we have a form of development not unlike that of the diffused or disseminated placenta. The belief that the lacunæ were really large cavities, as they had the microscopic appearance of being, and not the maternal vessels greatly dilated, was held as a truth, proved and indisputable. It was through this belief that two other deceptive appearances were received as truth; that the villi floated in the maternal blood, and that the epithelium covering them appertained to the fœtus instead of the mother. It has seemed thus necessary to review the anatomical and physiological modality of placental formation in order *now*, and not earlier, to investigate some of the more common forms of placental disease.

The paper being before the Society for discussion, Dr. Clarke inquired if Ercolani's system had been still further illustrated by observations from disease.

DR. MARCY replied that it had. He would further remark that, only a few days after the separation of the fœtus, careful searching would enable us to find the line of demarkation between the maternal and fœtal villi.

DR. FIELD observed he had special reason to be interested in the question asked by Dr. Storer before the reading of the paper; he had himself previously detailed to the Society the difficulty he had in procuring abortion under three months. At other times the sound could hardly be once introduced without response. In certain difficult cases, and he could call to mind three such where he had been forced to procure abortion, it seemed as if it were impossible to do sufficient injury with the sound to disturb the relations of the fœtus and the uterus. Dr, Field proceeded in some detail to describe the difficulties he had encountered.

DR. NORRIS asked if air had been introduced. He had been called in the night to a case of abortion where the forcing in of air appeared to be the determining cause; this at the hands of an irregular practitioner. Separation of membranes and abortion speedily followed.

DR. FIELD was well aware of the efficiency of this method, but was afraid of it. Believed it had been known to cause almost instantaneous death.

DR. WHEELER recalled a fatal case, which had come to his knowledge, where air had been forced into the uterus through the imperfect working of a Davidson syringe which had been charged with water.

DR. MARTIN had knowledge of a number of cases where abortion had been, purposely and with but little difficulty, induced by a skilled use of Simpson's sound. Had known abortion to follow within twenty-four hours after recourse to this instrument. Ergot was of little help or use unless abortion or parturition had been already inaugurated by other means.

DR. MARCY showed a specimen from a recent abortion. The ovum will bear considerable disturbance so long as the placental site is not interfered with; but rupture of the membranes will ordinarily lead to a speedy casting off of the fœtus.

DR. WEEKS raised the question as to the *modus operandi* of air driven into the uterus in effecting abortion; had seen two cases lately, both the work of irregulars. In one, the air was introduced through a catheter, in the other the ordinary bulb syringe was used, the rectal tube having been inserted within the uterine os. In both instances abortion followed within forty-eight to sixty hours, with but little pain or hæmorrhage or disturbance of any kind, and apparently without danger to the patient.

DR. WHEELER remembered a case in which he had largely relied upon a flexible catheter, introduced and left *in utero*.

DR. MARTIN believed a frequent cause of abortion, if not, indeed, the prevailing condition, to be a partial separation at the edge of the placental site, which, with the consequent and subsequent hæmorrhage, acts as a source of still further excitation. The resulting clot serves the purpose of a wedge; and if this state of things be permitted to continue and extend, abortion must ensue.

DR. STORER believed in the correctness of Dr. Martin's position, but superadded, and of necessity present, is a degree of nervous irritability. If this can be controlled, abortion may be at times prevented, although the mischief described by Dr. Martin has been already accomplished. Dr. Chapman's suggestion of heat applied to the sacral region is of especial value under these circumstances: on the other hand, cold so applied will encourage the abortion. An abortion which has been threatened and escaped will leave a permanent impression of injury upon the placenta, as an investigation at time of birth, months after, will prove. Dr. Storer hoped Dr. Marcy would continue his researches, and especially that he would instruct the Society upon the pathology and other phenomena of membranous dysmenorrhœa.

DR. WEEKS' question as to the mechanism of abortion, obtained by the introduction of air into the uterus, was again raised.

DR. MARTIN believed that whatever tends to increase or diminish the size of the cavity of the womb tends to produce muscular contraction, which, if the organ be gravid, may result in the expulsion of its contents. He called attention to the large number and variety of electrical instruments which were being exposed for sale, to be applied by the subject and worn in various ways for the purpose of procuring miscarriage.

DR. WHEELER reprehended resort to sponge-tent in the effort to cause abortion. In one instance, where abortion had already taken place, the woman died of septicæmia, for which the sponge-tent was believed to be responsible. This stricture was meant to apply to the puerperal state only; in the non-puerperal other conditions obtained, and the danger was less.

DR. M. L. THORN recalled the fact that Dixi Crosby was accustomed to propose for the procurement of abortion a saturated solution of alum introduced between the membranes and uterus and without rupturing membranes. The speaker asked the mode of action of this expedient.

DR. STORER suggested that such a solution left in the uterus must cause extreme exosmosis, and so, as Dr. W. S. Brown rejoined, empty the uterus through the contractions its distention would be likely to bring about.

DR. MARCY asked for experiences in mole pregnancy and hydatids.

DR. MARTIN responded with a recent experience in which patient had a fall and expected to abort early in pregnancy, but escaped. As gestation proceeded she became immensely anasarcous, the labia being so distended as to be almost diaphanous. Finally he was called in haste to find the woman floating in a pool of fluid which had run through the bed and upon the floor; she had given birth to a great mass of hydatids. The blood she discharged looked like currant juice, so impoverished was it. Gave ergot, used ice, resorted to compression. Then examined and brought away a pitcher, and perhaps a pail, full of hydatids. Placenta gave evidence of hardly more than four or five months' development: on further examination it proved to be separated at one point, and here, as a place of origin, had sprung the hydatids, — a growth still hanging from its attachment like a bunch of grapes. Fœtus when brought away showed that its growth had been arrested at, apparently, five months. An interesting fact remains for mention: the placenta was perfectly healthy, and fœtus not in the least putrid. The latter had probably continued to live, in a state of arrested development, until a short time before birth.

DR. CLARKE cited a case in which he attended a woman at full term and the whole placenta came away.

She got on very well for three days, when she was suddenly seized with violent pain and a placental-looking mass was extruded from the vagina. Dr. Holt, of Cambridge, examined it and pronounced it to be placenta. The woman said she had been conscious, for two years past, of a swelling at one side of the womb; but now it was gone. Specimen had no odor, and was not decomposed.

DR. STORER suggested, in explanation, twin pregnancy, with early blighting of a twin, which had afterwards been destroyed.

DR. MARCY regarded Dr. Martin's case one of great importance. It would seem as if a single cotyledon had developed in this extraordinary manner. Mole pregnancy is commonly limited to a development which takes place prior to the formation of the placenta, before the circumferential villi of the chorion at other points have atrophied. This is more frequently observed than the abnormity due to placental modification.

DR. STORER believed that the passage of what was intrinsically nothing more than coagula often gave rise to a belief in the extrusion of a mole. Again, in the unmarried, whatever may be the character of the product of conception, the question being raised if it is not a false conception, and nature having apparently made some effort to spare the woman, the doctor respects the feelings of the patient and patient's friends, and leaves them in their ignorance. Then there is a residuum of cases when the doctor makes a mistake. He had met upon the train not long since a gentleman whose wife, as was supposed, had long been the subject of uterine disease; frequently on the occasion of menstruation she would pass, with great pain, what appeared to be the exuviæ of membranous dysmenorrhœa. Another physician called in, who proved to be more sharp sighted, closely investigated the case, and found in the supposed product of menstrual decidua an impregnated ovum. The woman was one of those exceptional subjects who are constantly conceiving upon the slightest exposure, and the uterus had formed the habit of speedily casting off the embryo.

DR. M. L. THORN quoted the opinion of Dr. Tait, who declares that true membranous dysmenorrhœa always implies conception.

This both DR. STORER and DR. MARTIN doubted; honest women and unmarried have dysmenorrhœa every month, and pass their period in great agony.

DR. MARTIN had often been surprised to find to what extent an organized clot may simulate the placenta. Doctors often err in this direction. Old women and nurses make this mistake, with disastrous consequences, it may be, for the patient. The doctor recalled a case in which a woman was said to have miscarried ten weeks before. She was suddenly seized with renewed hæmorrhage, and a mass fell from her as large as a cocoa-nut; it was nothing less than the placenta, which had been all this time retained.

DR. MARCY remarked, in respect of the *false membrane*, that its histological character is very simple; and this he briefly described. All over its interior can be seen the casts of the utricular glands. It takes its origin in a hyperplastic condition of the epithelium lining the interior of the uterus.

DR. MARTIN detailed the history of a remarkable case of general or constitutional vaccinia in an infant, which contracted the disease from a secondary vaccination done upon the mother, from whose breasts it drew its support.

DR. STORER informed the Society that its Fellow, Dr. Campbell, of East Boston, who held a position in the present Legislature, had already shown his loyalty to those interests with the culture of which the Society was intrusted, by bringing forward a bill for the relief of shop-girls.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

STATED MEETING, JANUARY 22, 1883.

THE NEW YORK CODE OF ETHICS.

DR. LEWIS A. SAYRE presented a resolution to the effect that the delegates of the County Medical Society to the approaching meeting of the State Society at Albany should be instructed to vote in favor of the repeal of the Code of Ethics adopted at the meeting last year, and that they should be requested to use their best efforts to secure the passage of the same. On this resolution Dr. Sayre called for the ayes and nays, so that the position in regard to the matter of all present might be permanently recorded. There were at the meeting, unfortunately, a number of those officious members who were most active in carrying out the measure which disgraced the New York State Society in February last, and which has since been so universally and severely criticised both in this country and in Europe, and who, with their usual effrontery, had evidently turned out in force for the express purpose of choking off discussion on the subject. Through their efforts Dr. Sayre's motion was laid on the table. Dr. T. Gaillard Thomas, who was prevented from being present by being suddenly called out of town on professional business, wrote to say that he regretted this absence very much, as he should have liked to speak in favor of the resolution. "I believe," he continued, "that I represent the feeling of the majority of our best conservative men in saying that I consider the breaking down of the barriers, as was done last year, as disastrous in its effects, and very much to be regretted."

THE NATIONAL BOARD OF HEALTH.

A resolution by Dr. John C. Peters, to the effect that the Society should petition Congress to restore to the National Board of Health the powers of which it had been deprived, having been referred to the Comitia Minora (the executive committee of the Society), the Comitia, through the secretary, asked for more information on the subject before taking final action in regard to it. This information was given to some extent by Dr. Abraham Jacobi, who, at the request of Dr. Peters, offered a series of resolutions, declaring that by the reduction of the appropriation for the maintenance and work of the National Board of Health by Congress, last year, the usefulness of that body had been seriously impaired; that the profession looked with no little pleasure upon the labors and successes already achieved by the Board; that its work had compared favorably with the national health boards in Europe; that the investigations conducted by it, especially on the subjects of diphtheria, yellow fever, and disinfectants, had been of permanent scientific value; that most of these labors and researches had now been stopped, which was the more to be regretted because in most of the large cities the appropriations for local boards of health had been increased on account of the

increasing importance of their work; that it was felt that no money could be spent with greater advantage to the nation than that which was devoted to the maintenance of the public health, and that therefore the Medical Society of the County respectfully urged upon Congress the importance of increasing the funds appropriated to the National Board of Health to at least the former amount. In presenting these resolutions Dr. Jacobi said that personally he had missed very seriously the bulletins of the Board, and the supplements to these, which he regarded as one of the most important features of its work. On motion of Dr. Sturgis the matter was again referred to the Comitia Minora with power.

THE DIFFERENTIAL INDICATIONS FOR THE USE OF DYNAMIC AND FRANKLINIC OR STATIC ELECTRICITY.

DR. A. D. ROCKWELL then read a paper on the above subject. In commencing he said that since a distinguished college professor had recently announced in one of his lectures that a simple faradic apparatus was all that was ever practically required in medical electricity, he thought it was still in order to offer contributions on this subject. It was not to be supposed that any one form of electricity was applicable in all affections or in all stages of the same disease in which the use of this agent was called for. For instance, in hemiplegia with small impairment of electro-muscular contractility, if electricity were employed at all, faradization, and with a very mild current, would be the only form applicable, while in paraplegia accompanied with very marked diminution of electro-muscular contractility the galvanic current was unquestionably called for, and the galvanic current alone. The difference in the character of the two currents was well shown in facial paralysis due to cold, and doubtless of rheumatic origin, in which the muscles did not respond at all to faradization, but acted promptly under the influence of galvanism. Again, there were well-founded physical and physiological reasons why in certain pathological conditions the constant current should be employed in the special manner known as central galvanization. In the majority of diseases in which electricity was called for at all, however, it might be stated that the application of each one of the three forms now in use was appropriate at different periods. In neuralgia the galvanic current was, as a rule, of the most utility, but at the same time there were certain forms of pain in which faradization was not only invaluable but the only mode of applying electricity which was of any service whatever in relieving the suffering. The law could now be laid down, he thought, that in the great majority of cases of neuralgia in which firm pressure over the nerves affected elicited tenderness galvanism was called for, while in those cases in which pressure produced no effect the faradic current was the appropriate form. The measure of benefit to be derived from one or the other depended, therefore, on the special features of each individual case.

In the class of cases in which there was general debility of the system faradization was undoubtedly indicated on account of its special constitutional tonic effects. That electricity was not merely a stimulant, but also a tonic agent, had been pointed out by the writer a number of years ago. The enunciation of this view had attracted a good deal of attention both at home and abroad at the time, but while it had been acted upon practically to a considerable extent in Germany, the matter was still almost entirely ignored in this country. Asthenopia, in which the muscles of accommodation were affected, demanded the use of the faradic current alone. This was also true of the paralysis following diphtheria, in which galvanism had but little effect. Dr. Rockwell said that he had had an exceptionally large experience in the latter class of cases, in many of which the affection was so obstinate that nature had been unable to effect a cure, and he related one or two instances by way of illustration. One was the case of a lady, twenty-five years of age, living in New Jersey, whom he was called to see in consultation. All four of her extremities had been paralyzed for three months, and there was in addition ptosis of the left eye and double vision, so that it was altogether one of the most severe cases that he had ever met with. Under the use of faradization she was able to leave her bed in three weeks.

Among the affections in which galvanism was especially called for, on the other hand, was spinal irritation or neuralgia. It was also particularly indicated in certain sequelæ of cerebro-spinal meningitis, such as excruciating pains in the eyes, head, and back of neck, and stiffening of the muscles, either with or without convulsive seizures. In exophthalmic goitre he was able to report some cases improved, and some cases actually cured, by the use of galvanism, which was also called for in cases of the loss of sense of taste or smell. In diseases of the skin galvanism was of the most service, and it was of the most remarkable efficacy in herpes zoster. In electro-surgery galvanism was, of course, used exclusively. In extra-uterine pregnancy it was perhaps not generally known how very efficient galvanism was in causing the speedy death of the fœtus. In chorea the character of the affection and the condition of the patient would determine which form of dynamic electricity was to be selected. If the general health were good, central galvanization would be of the most service; but if there were anæmia and debility present, general faradization was called for instead. In amenorrhœa and dysmenorrhœa also the form of electricity to be employed would depend upon the special features of each individual case.

Franklinism, applied by means of insulation, sparks, or the use of a roller, was called for as an adjunct or supplement to dynamic electricity, and was an invaluable agent in its appropriate place. All physicians were familiar with cases in which a remedy which acted well at first seemed after a time to lose its effect. The same was found to be true of galvanism and faradism in certain cases, and in some of these very excellent results were secured by resorting to franklinism.

In the treatment of neuralgia, franklinism, as a rule, was not comparable to dynamic electricity; but in certain chronic cases of synovitis and contractured muscles it proved a very effective agent. In electro-diagnosis, again, it was of but small value as compared with the other forms. It could be seen, therefore, that franklinism was of much more limited application than dynamic electricity. The beginner in electro-therapeutics should by all means commence with the study of the latter, and not till after he had thoroughly mastered the subject need he take up that of franklinism.

DR. A. JACOBI thought the paper a very complete one, to which little could be added, and that the conclusions of the author were correct. He quite agreed

with Dr. Rockwell in his opinions in regard to the application of electricity in paralysis following diphtheria, a subject in which he had had a very considerable personal experience. There were certain cases of this character which were very dangerous, and which would prove rapidly fatal unless they were treated with great promptness and with great success, namely, those in which paralysis of the respiratory muscles occurred. All the cases of diphtheritic paralysis which he had seen prove fatal were of this kind, with the exception of a few in which the muscles of deglutition having become paralyzed, food got into the lungs and set up pneumonia. Sometimes the paralysis of the respiratory muscles came on very suddenly in the course of ordinary diphtheritic paralysis, and unless relief were very promptly afforded, the patient would die of apnœa. There was then no time to employ medicines by the mouth, and strychnia, if it were administered at all, was to be given by hypodermic injection.

Dr. Lewis A. Sayre remarked that his experience in the use of electricity during the past fifteen or twenty years was entirely in accord with the results stated by Dr. Rockwell in his paper.

Dr. John P. Garrish thought that the mistake was often made in practice of employing electricity at too early a period. While it was of great efficacy, no doubt, in many chronic affections, he did not believe that it was of any value whatever in acute disease.

Dr. Jacobi said he would enunciate a general rule for guidance in selecting the form of dynamic electricity to be used in any given case, which he believed to be a sound one, but in regard to which he would like to have an expression of Dr. Rockwell's opinion. It was this: In all affections of the vaso-motor system and of the trophic nerves galvanism was to be employed mainly and perhaps exclusively. So far as he could recall the various conditions mentioned in the paper, he thought the treatment recommended was in accordance with this rule.

In reply, Dr. Rockwell stated that he believed that as a general law it held good, although there were some exceptions to be noted. For instance, facial paralysis of rheumatic origin and excited by cold, in which galvanism was called for, could hardly be placed in the class of affections mentioned. In this trouble faradization produced no contractions whatever. At first a very weak galvanic current was to be employed, and as the patient improved the strength of the current was gradually to be increased. Finally, the faradic current might be used.

Dr. Jacobi thought that this was perhaps not an exception to the rule after all. He had been under the impression that the faradic current was the proper one to use in this affection, but since galvanism was the more efficient agent, might it not be true that the paralysis was in reality due to a disturbance of the vaso-motor system? When the nerve-substance itself was affected, galvanism was of no benefit, and it seemed to him, therefore, that this was probably a disorder of the circulation, although there might be a rheumatic element in the case as well.

Dr. Mittendorf said that he had used faradism in cases of paralysis of accommodation with good effect, as well as for the relief of the pain which ensued after the use of the internal recti muscles when weak. In amblyopia due to alcoholism, tobacco, or loss of blood, he had employed galvanism with success.

The President, Dr. David Webster, had had very little experience in the treatment of amblyopia by electricity, and what he had had was not very favorable. In paralysis of the ocular muscles he had had good results from the use of faradization, though he believed its employment in this condition was contrary to the teachings of the books. His results with electricity in the treatment of amblyopia, asthenopia, and atrophy of the optic nerve had been so unsatisfactory, however, that he had about abandoned its use in these affections.

Dr. Chamberlain stated that, contrary to the experience of Dr. Rockwell, he had met with good results in the treatment of facial paralysis with the faradic current.

A member having asked Dr. Rockwell what his opinion was of the value of electricity in stricture of the urethra, he replied that he certainly had not met with the success which some others had claimed for it in this affection.

Another member also mentioned that he had employed it in severe cases of stricture, and had been altogether disappointed in its effect.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. Nancrede, Recorder.

Thursday Evening, January 11, 1883. The President, Dr. Tyson, in the chair.

Condylomatous Tumor of the Labium.

Exhibited by Dr. Nancrede for Dr. C. M. Seltzer.

Mrs. —— contracted syphilis nine years ago from her first husband. Has had specific treatment at intervals, but never prolonged beyond a few weeks each time. Condylomata and ulcerations around the vulva, anus, and perineal region were first noticed about three years ago. She first came under my observation and treatment June 1, 1882, at which time symptoms of her disease were very pronounced, such as cachexia, nervousness, nocturnal headache, ulcers on various portions of the body, numerous condylomata, of which the specimen exhibited was the largest, being a cauliflower-like excrescence springing from the left labium majus, having a pedicle about two and one half inches broad. The clitoris was hypertrophied, forming a knob one inch in diameter. There was urinary incontinence, and consequently severe excoriations of the external genitals. Potass. iod. and hydrarg. bichlorid. were given, upon which there was pronounced systemic improvement. Local treatment failed to remove the condylomata, hence on the 13th November two double ligatures were passed through the pedicle of the largest so as to divide it into three parts; they were then tied tightly, and the mass removed, and the stump cauterized with nitric acid. The clitoris was so sensitive even under profound anæsthesia that it was thought best not to remove it. The patient made a good recovery in ten days, including the cure of the urinary incontinence. Her second husband, to whom she has been married about six years, has no evidence of having syphilis. Her only child by her first husband has stricture of the rectum, and obstinate fissure of the anus, improvement of which only began upon the recognition of their specific origin, and the consequent line of treatment.

Dr. Nancrede suggested the reference of this specimen to the Committee on Morbid Growths, since two somewhat similar specimens had been presented by Drs. Formad and Baer which were myxomatous fibromata.

Although not due, as in the present instance, to the irritation of some sore or abrasion by the discharges, etc., in a syphilitic, yet probably their histological structure was identical.

SMALL TUMOR OF THE HEAD OF THE PANCREAS.

Presented by DR. E. T. BRUEN.

The mass herewith exhibited occupies the head of the pancreas, and is about two and one half inches in diameter. When removed from the cadaver it was closely adherent to the common bile duct. The growth is of a colloid nature, but its histological character is as yet unsettled by microscopic examination. There were no secondary deposits in any other viscera, as is the rule in colloid growths. The patient was a male, aged about sixty-five years. For two years prior to date of his death there had been intermittent attacks of jaundice. This had been attributed to catarrh of the biliary duct, which had developed itself during an attack of malaria. The case was under my care for two months. At first the symptoms of chills and fever led to treatment for malaria, but as the jaundice gradually deepened, treatment for the supposed catarrhal state of the bile duct was instituted. The futility of a well directed and usually successful treatment was the special indication of some more substantial cause. Hepatic trouble or biliary calculi were readily excluded in this case, but there was nothing to fasten suspicion on the pancreas. There was constipation with clay-colored stools. There was a febrile movement of a hectic type — the so-called hepatic fever, accompanied by irregular chills. The intestinal indigestion, so valuable a symptom in many cases of pancreatic disease, was not marked.

Indeed, without exception, the negative results of the clinical record are of the most discouraging character. The case is presented because each case of pancreatic disease ought to be recorded, so that many cases viewed collectively may contribute to the clearness of a future distinct picture of pancreatic disease.

DR. FORMAD said that he had now on record the notes of five or six cases of cancer of the pancreas with marked jaundice where he had made the autopsy. It seemed to him that the jaundice was most persistent in primary pancreatic carcinoma from pressure on the bile duct. He was present at the autopsy of this case, and did not think that the tumor was carcinomatous, as there would then probably have been secondary growths in the liver. The growth was probably a cystic colloid.

DR. BRUEN would like to call the attention of the Society to the fact that he had about a month ago presented a specimen of carcinoma of the pancreas, and had then referred at length to some forty cases of jaundice due to primary carcinoma of the head of the pancreas lately reported by another observer. From these records it was demonstrable that jaundice was an invariable symptom of primary hard carcinoma of the head of the pancreas, while it was uncommon when the disease was secondary or affected other parts of the organ.

DIAPHRAGMATIC HERNIA.

Exhibited by DR. JAS. TYSON.

The patient from whom these specimens were removed was a German between twenty-seven and twenty-eight years of age at his death. He first consulted me on June 21, 1880. He had then been ailing since February, 1878, and had been unable to work in that time. At the date referred to he was stretching when his wife suddenly pretended to tickle him. He quickly threw down his arms, and at that moment felt a sensation of "pain on the left side in the neighborhood of the heart." At the same time he felt faint and cold. In five or ten minutes these sensations passed away, but he remained very much frightened. When he first visited me he complained of shortness of breath and beating of his heart, although the latter was better when he was quiet. He could not even walk across the floor without becoming completely out of breath, but he said he was not short of breath when the accident first occurred. He had also a peculiar puffing expiration, which did not occur, however, with every act of expiration, but once in four or five. This was so characteristic that one of my friends to whom I sent him spoke of him as my "puffing German." There was no cough. Physical examination revealed on inspection almost total absence of movement of the chest wall in the upper half, the respiration being almost purely abdominal. The upper percussion border of the heart corresponded with the junction of the third rib with the sternum, and the right border with the middle of the sternum. The apex beat was in its normal position, but was more diffuse than in a strictly normal state. Pulmonary percussion appeared normal except below the left scapula where resonance was less than in the corresponding situation on the right side. Vocal fremitus was, however, impaired over the whole of the left lung. There were no abnormal cardiac murmurs. His pulse was 72 after the examination was over. He was treated at various times with digitalis, bromide of potassium, chloral, tonics, etc., and even a blister was put over his heart, with the view that there was some cardiac or pericardial affection, although the physical signs were wanting. There was no improvement, although at times the dyspnœa, which was the most distressing symptom, seemed sometimes less; but it always interfered with any exercise whatever. He would walk sometimes half a mile with great difficulty. Notwithstanding this he was encouraged to take exercise. His sleep was unsatisfactory, he would dream and wake up in a great fright. He could always lie upon his left side with more comfort than upon his right. He continued under my observation for a year. I saw him in the latter part of August, 1881, when he seemed a little better. After that I heard nothing of him until I learned of his death, which occurred December 15, 1882, from obstruction.

At the autopsy it was ascertained that about twenty inches of the large intestine with its corresponding mesentery and almost the whole omentum had ascended through the œsophageal opening of the diaphragm into the left pleural sac, encroaching upon the space occupied by the left lung until the latter was compressed into the apex of the left pleural sac and was reduced to a cylindroid mass about fifteen centimetres in length and half as many in diameter. There was no hernial sac, the opening being that for the œsophagus. The case would therefore be technically called one of hernia diaphragmatica spuria. The heart was displaced to the right, but was otherwise normal; the liver was slightly fatty, but the other viscera were normal. It is not unlikely at the moment referred to in the history when the patient threw down his arms that a small portion of the omentum or mesentery slipped through the œsophageal opening, and that subsequently and more or less gradually the vacuum tendency of the pleural sac in each act

of respiration caused the remainder of the mass to be drawn in until the entire cavity was occupied. This accounts for the fact that there was no dyspnœa at the beginning, but that it gradually increased as the thoracic space was intruded upon. In vol. lxxxi, 1882, of Virchow's Archives will be found an exhaustive article on Diaphragmatic Hernia, in which two hundred and ninety-one cases are collated. In a somewhat hasty examination of this paper I have been unable to discover a single case so long under observation as this — nearly four years. Many cases were discovered at the autopsy which had been unsuspected, others were congenital, and others were traumatic.

DR. FORMAD related some facts confirmatory of the history given by Dr. Tyson.

DR. BRUEN asked if there had been any hiccough? If so was there any dysphagia with solid food? Finally, did the physical signs suggest pneumothorax?

DR. ROBERTS made some remarks with reference to the diagnosis and to the possibility of laparotomy in similar cases. He also asked whether the symptoms just preceding death were those of strangulation.

DR. DAVIS referred to thirst as a prominent symptom according to Lawrence.

DR. TYSON replied that Dr. Formad had told him that there was decided hiccough. There was no true tympany with the absence of the vocal fremitus. Nothing gave rise to any suspicion of its true nature. Thirst was marked. There was no dysphagia.

ULCER OF THE STOMACH IN THE ANTERIOR WALL; ADHESIONS TO THE ABDOMINAL WALL; HÆMORRHAGES AND PAIN; DEATH FROM MORPHIA HABIT.

Exhibited by J. H. MUSSER, M. D.

I am indebted to Dr. J. Henry Musser, of Lancaster County, for the privilege of presenting this specimen. I abstract from his notes the following history: I. I., aged seventy-one years, mill-wright. Fourteen years before his death he was attended by the doctor for hæmatemesis occurring after three days of nausea. Over a pint of blood was vomited, and considerable was discharged by stool the next day. In ten days he returned to work and enjoyed good health for two years, with the exception of occasional attacks of indigestion. Then a recurrence of nausea followed by a profuse discharge of blood, per anum, occurred. He made a full recovery, but pain after eating was now noticed. Two years subsequently he bled very much from a wound of the foot, was much prostrated thereby. This was succeeded by severe pain after eating with marked epigastric tenderness. The constant use of narcotics alone gave him relief. In November, 1873, he was again under Dr. J. Henry Musser's care, and was treated for gastric ulcer without any avail, save when he exhibited narcotics. He resorted to the use of morphia, and continued its use during the remainder of his life. Change of diet did not influence the pain, and he partook of a laborer's fare. In 1877 a small tumor to the left of and several inches above the umbilicus, hard, tender, and apparently involving the abdominal wall, was discovered. For several years he worked in a country saw mill, using one drachm of morphia a month. Heavy lifting aggravated his pain. August, 1882, the doctor was again called in to find the patient confined to bed, much emaciated, and with complete anorexia. Death took place three weeks later, during which time he had taken no nourishment, but had used morphia freely. The habit had been acquired, as his friends thought he suffered but little pain. The only anatomical alteration noted at the autopsy was the change in the stomach. The organ was enlarged and contracted (hour-glass) towards its fundus. The anterior wall, one third of the distance from the fundus, and at the point of constriction, was adherent to the abdominal parieties to the left of the median line, three inches above the umbilicus. Opposite to the point of adhesion in the mucous membrane there was a small ulcer two lines deep and six in diameter with clean-cut edges, a healthy floor, and surrounded by cicatricial tissue for a radius of one inch. Indoubtedly the ulcer would have healed entirely had not the morphia habit cut off the patient.

Remarks by DR. J. H. MUSSER. It is plausible to theorize that the first hæmorrhage, taken with the profuse hæmorrhage from the foot, was due to the patient having been of a hæmorrhagic diathesis, and that the second gastric hæmorrhage was from the same cause, and was attended by a hæmorrhagic infarct with subsequent development of the ulcer. Especially is this possible as it was only after the second hæmorrhage that pain occurred, and this symptom is never absent, "except in cases which run a rapid course." (DaCosta.)

DR. NANCREDE related the case of a "bleeder" then under his care, a *female* infant only thirteen months old where death was imminent from epistaxis.

DR. DUNN made some remarks on the general subject of hæmophilia and its treatment.

NEW YORK ACADEMY OF MEDICINE.

SECONDARY PUERPERAL HÆMORRHAGE.

AT a stated meeting of the Academy, held January 18th, DR. PAUL F. MUNDÉ, editor of the *American Journal of Obstetrics*, read a paper on the above subject. After speaking of the prominence which had been given to the subject of primary post-partum hæmorrhage, he said that that of metrorrhagia occurring later in the puerperal period had received comparatively little attention. The older writers, if mentioning it at all, simply alluded to the fact of its possibility; but some of the more recent authorities, among whom were mentioned Barker and Playfair, devoted more or less space to its consideration. All the latter acknowledged their indebtedness to the important paper of McClintock, which was published in 1851, and was really the first contribution of any value to the subject, as well as to the later communication of Bassett, of Birmingham, which appeared in 1872. At the meeting of the American Gynecological Society in 1880 Prof. Theophilus Parvin, of Indianapolis, read an exhaustive paper on secondary puerperal hæmorrhage, which was afterwards published in volume v. of the Transactions of the Society; but as he was not present at the meeting the matter had escaped his notice until after he had prepared the present paper, when his attention was called to it by a friend. As the case which formed its basis presented certain features, however, which were not alluded to by Dr. Parvin, and especially as secondary hæmorrhage, though more rare, was scarcely a less serious danger than primary, he did not consider that any apology was needed for his presenting the subject to the Academy.

The case to which he alluded was the following: On the 1st day of August, 1882, he was hastily sum-

moned in consultation to see Mrs. S. G., twenty-five years of age, the mother of three children, who had been confined with her fourth child on the 16th of July. Labor having lasted twenty-one hours efforts were made to apply the forceps, but they twice slipped off the head. One hour later the cranium was perforated and the forceps again applied, but again they slipped. The head was then crushed with the cephalotribe and the delivery effected, when it was found that the child was the subject of hydrocephalus. The placenta was adherent, and there was quite a profuse hæmorrhage. This was readily controlled by ergot and the other agencies employed, but it was found that the cervix had been quite badly torn during the labor. The day following the temperature was 102° F. and the pulse 120, while the lochial discharge was very fetid. This condition was corrected, however, and the patient did well until the eleventh day, when the lochia again became fetid. The temperature went up once more, and ranged between 101° and 103° F. All appetite for solid food was absent, but she was able to take a considerable quantity of fluid nourishment and stimulus. On the fourteenth day a profuse hæmorrhage set in, but as it was so long after the delivery it was not considered of any importance, and the medical attendant was not summoned until after the patient had become very much exhausted in consequence of the loss of blood. Ergot was administered, and the hæmorrhage also controlled by injections of hot water, after which the vagina was tamponed. When Dr. Mundé reached the bedside he found the fundus on a level with the umbilicus, and that the right cornua reached to a considerably higher point than the left. The hæmorrhage had then entirely ceased; but, fearing that this cessation was only temporary, and that its return would certainly prove fatal, he removed the tampon in order to secure a contracted condition of the uterus. As he did so quite an offensive odor was perceptible. On introducing his hand into the uterus he found it filled with coagula, and while removing these he found that at the fundus the endometrium was in a soft and pulpy condition, apparently similar to that found after death in cases of septic puerperal endometritis. No portion of the placenta could be anywhere detected. The uterine mucous membrane seemed to be much thickened, and each horn of the uterus to be separated by a circular band. Having taken out all the coagula, of which there were several handfuls, he introduced a long tube and thoroughly washed out the cavity with hot carbolized water. Then, placing a large cylindrical speculum in the vagina, he injected half an ounce of pure tincture of iodine into the uterus, and finally put a cotton tampon in the vagina as a safeguard against further hæmorrhage, at the same time requesting that the uterus should be very strictly watched, so that if there should be any return of the hæmorrhage it might be detected at once. The patient was now in a state of extreme exhaustion, but experienced no pain, nor did any shock follow the measures adopted. The pulse became so weak that brandy and ammonia were administered by hypodermic injection. Notwithstanding the exhausted condition it was thought advisable to give ergot hypodermically also, so as to leave no precaution against a return of the hæmorrhage untaken. Bottles of hot water were placed at the feet, and upon leaving Dr. Mundé suggested that after the tampon was removed from the vagina injections of tepid water should be made from time to time in order to prevent any accumulation of coagula.

After he had gone the patient sank into a state of such profound collapse that the attendants despaired of her recovery from it, but she afterwards rallied, and when he called the next day he found her feverish, and with a hectic flush, which, with a sweetish odor which there was about her breath, made him fear the presence of septic endometritis. He washed out the uterus with a solution of permanganate of potassium of the strength of one sixth, and ordered ten grains of salicylate of soda to be given every three hours. He could not but regard the prognosis as very unfavorable. As he was at the time in attendance on another case of confinement, Dr. Mundé now withdrew from the case, and its subsequent history was learned from the attending physician. The temperature varied from 101° F. to 103° F., and the stomach became very unmanageable. After a few days injections of sulphate of quinine, one drachm to the quart of water, were resorted to, and seemed to be followed by good results. The patient, however, recovered very slowly. Altogether Dr. Mundé thought it was the most desperate case which he had ever met with in which recovery followed.

He then proceeded to speak of secondary puerperal hæmorrhage in general, and first enumerated the causes of this accident as given by Bennett and Barker. To these he thought distended urinary bladder should be added, as suggested by Winkel. Playfair, quoting a Brazilian author, had spoken of malarial congestive chill as a cause. Barker mentioned five cases due to malaria in his paper on malarial puerperal fever, and Dr. H. T. Hanks had also reported one similar case. Winkel laid special stress on too early getting up as a cause, and diseases of the inner surface of the uterus (and chiefly endometritis) were spoken of by Winkel alone. In the case described in the paper, although, fortunately, there was no opportunity to verify the matter by an autopsy, Dr. Mundé believed that there was endometritis with a hyperplasia resulting in a fungoid proliferation of the mucous membrane, and finally a superficial slough of the hyperplastic material. At the time that he saw it, however, he was not aware that puerperal septic endometritis had ever been assigned as a cause of secondary hæmorrhage.

(2.) The date of secondary hæmorrhage varied very greatly according to circumstances. As a rule, it might be stated, that the greater the attention that was paid to securing contraction of the uterus immediately after labor, and to its subsequent watching, the less would be the probability of the accidents occurring. Hence in well regulated lying-in hospitals it was found to be very rare. Friction should ordinarily be made over the uterus for half an hour after delivery, by which time the organ was usually permanently contracted. In addition ergot should always be given after labor. Secondary hæmorrhage occurred, perhaps, most frequently about the tenth day, and was then generally attributable, in part, at least, to the exertions made in getting up. Hæmorrhage coming on after the patient had gotten up was due, as a rule, he thought, either to the retention of a portion of the placenta or to endometritis. Barker referred to cases occurring as late as the fifth and sixth weeks after confinement. Sometimes there was prolonged oozing, and this was not unfrequently due to laceration of the cervix. It was a mistake, however, he believed, to put sutures in the cervix at an early period after labor.

(3.) *Diagnosis.* In cases of hæmorrhage occurring late it might sometimes be necessary to dilate the uterus with a sponge-tent in order to make an examination of the cavity with the finger.

(4.) The significance of secondary hæmorrhage depended partly on the amount of blood lost, and partly on the origin of the flow. In the case related there could be no doubt that a very slight additional loss of blood would have destroyed life.

(5.) *The means of checking the hæmorrhage.* Pure tincture of iodine, as recommended by Lente and others in puerperal hæmorrhage, and by Emmet in non-puerperal hæmorrhage, he believed to be very efficient as a hæmostatic, and also an excellent disinfectant. It did not form hard coagula, like the persulphate of iron, although Dr. H. P. C. Wilson, of Baltimore, had found that when iron and glycerine were used together in equal parts, these hard coagula could be avoided. The use of a cylindrical speculum was to be recommended in making such injections, on account of the protection which it afforded to the vulva and vagina. The tampon was more applicable in secondary than in primary puerperal hæmorrhage; but it was never to be employed unless the uterus was so contracted, and it was possible to have the fundus so carefully watched that no internal hæmorrhage could take place. In the case related, it would be remembered, the hæmorrhage did not come on until more than two weeks after delivery, and the tampon was used simply to guard against external hæmorrhage. Ergot was, of course, a valuable agent. In the case mentioned it might, perhaps, have been omitted on account of the exhausted condition of the patient, for fear of its producing further collapse; but it seemed to do no harm, and its use was justified on the ground that any return of the hæmorrhage whatever would probably have proved fatal. Very likely the hot-water injections alone might have been sufficient; but it was thought best to take no chances in the critical condition of the patient. As a rule, then, the same measures were applicable in secondary as in primary hæmorrhage. When pelvic congestion was present saline purgatives were called for. In the earlier periods after labor it was often necessary to clear out the coagula from the uterine cavity. When laceration of the cervix was the cause of hæmorrhage appropriate astringents were to be applied by means of cotton. In this paper, Dr. Mundé said, no attempt was made to go over the whole ground of secondary puerperal hæmorrhage. He aimed merely to add another case to those already on record, and to discuss a few points that had arisen in connection with it.

In conclusion he presented a number of simple rules, the observation of which, he said, would greatly diminish the chances of both secondary and primary hæmorrhage, the principal of which were the following: Always keep a compressing and supporting hand over the fundus from the time the head appears at the vulva until the uterus is permanently contracted after the delivery of the placenta. Use no haste in removing the placenta. Give ergot immediately after the birth of the child. If chloroform has been used during labor, or there is much exhaustion present, administer the ergot hypodermically; and the needle should be inserted to the depth of an inch in the abdominal walls in the vicinity of the umbilicus. It is always well, under any circumstances, to be prepared to give a hypodermic injection of ergot at a moment's notice. Always have ice ready at hand. It is more agreeable to the patient than hot water, and there is often more or less difficulty in procuring hot water at the right temperature; as it is apt to be either so hot as to be scalding, or else not sufficiently hot to do any good. Be sure that no coagula are left in the uterine cavity. Put the child to the breast at an early period. Apply an equally tight abdominal bandage after the delivery of the placenta, and if there is any tendency to hæmorrhage, place a compress under it in the position of the uterus. Examine the conditions of the perinæum and cervix carefully. See that the bladder is not allowed to become distended. Keep the patiently perfectly quiet for at least ten days.

A second paper, the subject of which was Eczema: Its Pathology, and the Principles of its Treatment, was read on this occasion by Dr. E. B. Bronson.

Recent Literature.

Dr. Norris's Third Corpuscle of the Blood. A Criticism and a Refutation. By Mrs. Ernest Hart. Reprinted from the *London Medical Record*, October 15, 1882. London: 12 pages.

Dr. Richard Norris, of Birmingham, England, claims to have discovered that the white corpuscles of the blood shed the body of the cell by peeling off, setting the nucleus free; the latter then enters the circulation as a colorless disk, which is ordinarily invisible because it has the same refractile index as the *liquor sanguinis*; the disks gradually become colored by the endogenous secretion of hæmaglobin. He then applies this history to set aside many established views concerning the physiology and pathology of the blood. He has presented his own opinions in an octavo volume illustrated by numerous plates. It would be a revolution to accept Dr. Norris's views, to which, however, we could give little credence *a priori*. His conclusions have been subjected to telling criticisms by Mrs. Ernest Hart. Norris's principal observation was that by certain methods of treatment colorless disks could be found in the blood and photographed. Mrs. Hart has repeated many of his numerous and varied experiments, and shows that the methods employed create the colorless corpuscles out of the red corpuscles by removing in one manner or another the hæmaglobin. The basis of Norris's theories is thus taken away, and with the base fall all his far-reaching deductions built on it. We think Mrs. Hart has made, in a very suitable and impersonal manner, a severe arraignment of theories that can hardly be deemed well established.

Variola. A Series of Twenty-One Heliotype Plates Illustrating the Progressive Stages of the Eruption. Boston: Samuel A. Powers. 1882.

These plates, twenty-one in number, represent the appearance of variola at different stages of the eruption. The first sixteen pictures show its appearance on the same patient from the third to the fourteenth day. The other plates are also of patients in the Boston Small-Pox Hospital, who were under the care of the City Physician. One of these plates appeared in the last annual report of the Boston City Physician.

The heliotypes are published and copyrighted by Samuel A. Powers, superintendent of the hospital, who, we understand, took the photographs.

Medical and Surgical Journal

THURSDAY, FEBRUARY 1, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

REGULATION OF PLUMBING IN BOSTON.

THE proposed ordinance for the regulation of plumbing in Boston, now under consideration by a conjoint committee of the city government, contains certain curious and noteworthy conditions. It provides for an inspection of the plumbing of all new buildings, enumerates the requirements, and provides that no water shall be admitted to the building until these requirements are met. The objects of such a regulation are supposed to be the maintenance of the public health, but in the bill no mention is made of the Board of Health.

Such regulation of a system of piping so easily adapted to the ventilation of the public sewers into sleeping-rooms and public work-rooms, and so intimately connected with the health of so many individuals who can have nothing whatever to do with its proper construction, is a most worthy subject for the attention of a city government. The evils which may follow careless plumbing in tenement houses, hotels, and work-shops, are sufficiently evident to make it a matter of vital interest as regards the public health. According to existing regulations any evil which may arise comes directly under the supervision of the Health Board, and to them is committed such powers as the public good demands. They have at present the right of interference in all existing plumbing whenever a nuisance can be shown to exist, and to them the public look for instruction and advice upon the subject. They possess already knowledge and experience upon this intricate subject, and to them naturally the preliminary inspection should be referred. Should the proposed regulation become a city ordinance Boston would be the only city, we believe, where plumbing is regulated at all, where it is not under the supervision of the local health board. Undoubtedly it is better that the matter should be under the control of the Inspector of Buildings than entirely without regulation, but the present draft of a bill has no clause looking to present or future amendment in any evil, however great, which may be present in plumbing as it now exists.

— The coldest inhabited town in the world is, according to *L'Union Médicale*, not Irkoutsk, as has been formerly believed, but Verchojansk, in Siberia. In this place the mean temperature during the month of January, was —43° F., in February, —56° F., in March, —37° F. Once the thermometer recorded —81.4° F.

REGULATION OF ATHLETIC SPORTS AT HARVARD UNIVERSITY.

IN accordance with our promise in the last issue of the JOURNAL we revert to the part of the last report of the President of Harvard University which concerns itself with the regulation of athletic sports among the students.

A first committee of the Faculty, appointed last spring to examine into the existing methods of maintaining and conducting out-of-door sports, conferred with both graduates and under-graduates specially interested in them, and reported that a standing committee of the Faculty ought to be appointed to regulate athletic sports, and that those institutions whose students are represented in the Collegiate Base-Ball League should be requested to unite with Harvard in prohibiting games with professional clubs. These recommendations were adopted, the standing committee was appointed, — the Faculty thus assuming for the first time a direct responsibility for the character and extent of athletic sports, — and communication with the other colleges resulted in a general agreement to unite in prohibiting base-ball games with professional clubs, Yale alone refusing to concur, on what grounds we neither know nor are able to surmise.

The committee of the Harvard Faculty has, in addition, forbidden all college clubs to play or compete with professional clubs, and decided that no student shall belong to a boat crew unless he can swim, and that no student shall engage in any athletic contest until he has been examined and pronounced fit by the director of the gymnasium. The number of match games of ball has been reduced and confined to Saturdays, and professional "trainers" have been denied access to the grounds and buildings of the university except by special permission of the committee.

These restrictive measures have, on the whole, the President reports, commended themselves to the judgment of the whole body of students and graduates, and even the young men most active in athletic sports had perceived that the college competitions were running to excess. He justly remarks that "when games are made a business they lose a large part of their charm; and college sports cannot approach the professional standard of excellence without claiming the almost exclusive attention of the players, and becoming too severe, monotonous, and exacting to be thoroughly enjoyable. The most devoted college athletes have repeatedly rebelled against what they thought too strict or too prolonged training. Moreover, a high standard of excellence tends to make the number of persons who actually take part in athletic sports very small, the considerable number of tolerably good players being driven from the field, and reduced to the unprofitable position of mere lookers-on."

As the result of an investigation as to standing on the college rank lists of students conspicuous in athletic sports, the committee found that of the eighty-four different students who were members of the university crew, base-ball nine, or foot-ball eleven from 1873 to 1881, more than a quarter stood above the middle of their respective classes, and the average

standing of the whole number was represented by seventy-two in a supposed class of one hundred. It was noticed that the base-ball players had on the average a lower rank than the rest, — seventy-six in a supposed class of one hundred, — the explanation probably being that the base-ball campaign occurs in April, May, and June, at the period of the annual examinations. The perseverance, resolution, and self-denial necessary to succeed in athletic sports when associated with lack of interest in scholarly pursuits or with dullness or slowness of mind are still very positive qualities, and that they may prove very valuable in the active occupations of later life is fully recognized by the college authorities.

"In the recent conferences between the committee of the Faculty and the students and graduates interested in athletic sports, and in the general discussion of the subject throughout the university," President Eliot says that "very little difference of opinion has been exhibited as to what is desirable in the conduct of these sports. It is agreed on all hands that the increased attention given to physical exercise and athletic sports within the past twenty-five years has been, on the whole, of great advantage to the university; that the average physique of the mass of students has been sensibly improved, the discipline of the college been made easier and more effective, the work of many zealous students been done with greater safety, and the ideal student been transformed from a stooping, weak, and sickly youth into one well formed, robust, and healthy. It is also agreed that athletic competitions, though necessary to the maintenance of a proper interest in the general subject, may easily run into excess, and on that account need to be kept within discreet limits; and that the whole spirit of college sports and contests should be that of amateurs who are amusing themselves, and not that of professional players who are earning a living, and seeking a reputation for its pecuniary value."

This whole subject is one of extreme importance to the youth who are going to be the men of the country, and we are glad to feel that it has thus far, since receiving their direct attention, been managed with so much judgment and discretion by the college authorities at Cambridge.

PHILADELPHIA WATER SUPPLY.

A CURIOUS wager is now being decided in Philadelphia, which is not without medical interest. The Schuylkill River, which supplies the drinking water to the greater portion of the city, has lately been quite low, and covered with ice; as a result the water has had a bad taste and odor, and by most persons it is regarded as unwholesome. To test it a physician is said to have offered fifty dollars as a prize for any one who would have the temerity to drink a quart of it for ten days in succession. This offer has been accepted, and at a variety entertainment in the upper portion of the city, each evening, the doomed man comes on the stage, the stipulated amount of water is brought in, and he takes his draughts to slow music before a sympathetic audience. Although he hastens to neutralize it with sundry alcoholic mixtures, it is not believed that he can hold out to the end, for it is the agreement that if he vomits or dies he will lose the prize.

The explanation given by the authorities of the bad quality of the water is that some old gas tanks have been washed up at Reading, and the refuse allowed to be discharged into the Schuylkill. The low state of the water makes the contamination more perceptible, while the ice has deprived it of the purifying action of the air. The general complaint against the water has attracted unusual attention to the water supply. Unfortunately, along the river, above the city, are a number of manufacturing towns, which drain into the Schuylkill, and as each year the capacity of the river gets smaller compared with the size of the city, it is evident that measures must soon be taken to protect the water from pollution. A bill has just been introduced into the State Legislature creating a commission to prevent the pollution of streams, etc., which it is hoped will promptly pass, as there is no State Board of Health to look after sanitary interests, and if there were one the pollution of streams might be considered more important to manufacturers than their purity to the general health.

MEDICAL NOTES.

— The first case of small-pox known to have occurred in Boston for six months was discovered and removed to the Small-Pox Hospital, on Thursday, January 25th. The case occurred in a little girl of five, who with her mother returned from Baltimore on the 19th, after a visit of some months in that city.

— Numerous recipes are being given in the medical journals for making koumyss, or rather for making a substitute for the preparation of mare's milk, that alone properly deserves that name. The simplest of the directions is as follows: Fill a quart champagne bottle up to the neck with pure fresh milk; add two tablespoonfuls of white sugar, after dissolving the same in a little water over a hot fire; add also a quarter of a two cent cake of fresh compressed yeast; then tie the cork on the bottle securely, and shake the mixture well. Place in a room of the temperature of 50° F. to 95° F. for six hours, and finally in the ice-box over night. Drink in such quantities as the stomach may require. This, as will be seen, is very inexpensive. Care should be taken not to allow it to be used if it contains curds, which indicate too much fermentation; precaution should be observed in opening the bottle on account of the effervescent quality of the product. Some observers recommend a dilution of the milk with water, varying from one seventh to one half before the fementation.

— The Lamson affair in England ends with a touch of grim humor. The murderer had a life insurance of £1000, payable to his widow. Immediately after his execution claim was entered for its payment. The company objected on the ground that the assured had

died neither from natural causes, disease, nor unavoidable accident. The estate claimed, however, that though the death was a violent one, it was in no sense like a suicide, which would, of course, have annulled the policy. The assured had certainly not voluntarily delivered himself to the executioner; on the contrary, it could be maintained that he had yielded only with reluctance. The company paid the claim under a formal protest.

— The *Maryland Medical Journal* intimates that the medical department of the Johns Hopkins University will be only available to those who shall have taken the preliminary course of three years leading to the degree of A. B., and will have a curriculum extending over at least four years, so that candidates for its degree will have had to study for seven years. Blessed is the college, and especially the medical school, which is so munificently endowed that it can fix its standard of scholarship independently of the necessity to make a living for itself; in fact, which can from the first adopt the position of the sought and not the seeker.

— It is pointed out by an exchange that the "*Convallaria majalis*," *vulgo*, lily of the valley, recently so strongly recommended by Russian physicians as a substitute for digitalis, and otherwise, is described in Ray's catalogue, Plantarum Angliæ, published in 1670, and dedicated "*clarissimo viro* D. Francisco Willughby, *armigero, amico et Mæcenati suo, plurimum honorando*," to whose labors he owed much of his materials. Mr. Ray gives the uses of the plant in medicine as follows: "Usus præcipue in morbis capitis frigidis, ut apoplexiâ, paralysi, vertigine, epilepsiâ; hinc et in lipothymiâ. Insigne itidem errhinum exhibent pulverisati flores. — *Schrod.*" As lipothymia is an old name for syncope, and is coupled with vertigo, a notion of its strengthening the heart's action seems to underlie the whole. Indeed, the apoplexy referred to may have been intended for cerebral anæmia.

— A portrait of Oliver Wendell Holmes by Alexander, of New York, to be presented by his former pupils to the Harvard Medical School, has been on private exhibition for a few days in this city.

— The Medical Society of New York County held a special meeting on January 29th for the purpose of showing the State Medical Society what the feeling in the metropolis is in regard to the matter of the code. On motion of Dr. D. B. St. John Roosa the following resolution was passed: —

Resolved, That the Medical Society of the County of New York approves of the amendment to the by-laws of the Medical Society of the State of New York, adopted at the annual meeting in February, 1882, and that we indorse the system of medical ethics therein substituted for the former one especially because it leaves the matter of consultation to the discretion, the honesty, and the humanity of the individual practitioner.

— The death of another centenarian has recently taken place at Morristown, New Jersey. This was Mrs. Maria Appley, who is said to have been one hundred and four years of age. She took part in Washington's funeral procession in New York as one of the young girls who personated the thirteen original States. She retained her faculties up to the time of her death, and frequently insisted on being allowed to do the family washing even after reaching her hundredth birthday.

— Dr. A. Hiller, of Berlin (in *Zeitschrift für klin. Med.*, Bd. iv.), reviews the various cathartics that have been recommended for hypodermic use, and concludes that none of them is at once reliable and free from objections. Aloin is uncertain in its action, and has been given in doses of 0.8 without effect, and citrullin (from the colocynth), cathartinic acid (from senna), elaterin, enonymin, baptisin, etc., are all found to be either uneffective in moderate doses or to cause great pain and local inflammation. So that the writer concludes that pharmaceutical research is still inadequate for the solution of this problem, which, however, he believes will some time be solved.

— Among the new medical journals are two which promise to be worthy a long and honored life. They are both French and devoted to special subjects. The first is the *Revue Mensuelle des Maladies de l'Enfance*, and is to include hygiene, medicine, surgery, and orthopædics. It is published under the direction of Doctors Cadet De Gassicourt, Physician to the Hôpital Trousseau and De Saint-Germain, Surgeon to the Hôpital des Enfants-Malades, with numerous collaborateurs. The second is, we believe, unique in its field. It is the *Annales des Maladies des Organes Génito-Urinaires*, with the name of Professor Guyon at the head of its list of editors and collaborateurs.

— Dr. J. H. Girdner describes and figures a new phymosis forceps, to be introduced, with the blades approximated, into the orifice of the prepuce. When its extremity touches the glans, the foreskin being drawn forward, at the release of a spring the blades fly apart, carrying on each of their outer surfaces a sharp point which transfixes both mucous membrane and skin. The forceps then being drawn upon, the amputation is made, the steel points preventing the rolling of the mucous and cutaneous layers upon each other, which is so annoying an accident.

— A bill to create a State Board of Health will be again submitted at the present session of the Pennsylvania Legislature.

NEW YORK.

— The Hospital Saturday and Sunday collections this year, much to the disappointment of those interested in the movement, amounted only to a little over $20,000. The collections of 1879, 1880, and 1881 aggregated $113,362, or an average of nearly $37,800 for each year.

— The report of the Vaccination Bureau shows that in the year 1882 the physicians of the Board of Health performed 99,661 vaccinations. In the last seven years nearly 500,000 persons have been vaccinated by members of the bureau.

— Dr. George M. Beard, the well-known medical writer and specialist in diseases of the nervous system, died, after a brief illness, on the 23d of January. A post-mortem examination, made by Dr. T. E. Sat-

terthwaite, showed that death was due to embolic pneumonia resulting from an alveolar abscess of the superior maxilla. The funeral services in New York were held at the Broadway Tabernacle on Friday afternoon, January 26th, and the pall-bearers were Drs. A. D. Rockwell, James L. Little, W. A. Hammond, T. H. Kellogg, D. Goodwillie, Charles L. Dana, Messrs. R. T. Bush, and W. A. Crofut. The remains were then taken to Andover, Mass., where the final services took place in the seminary chapel on Saturday morning, January 27th. Dr. Beard was only in the forty-fourth year of his age, and by his death the profession loses one of the most original and industrious of its thinkers and writers.

CHICAGO.

— *The Preliminary Examinations.* — The rule of the Illinois State Board of Health, that after the present college session diplomas will not be recognized from colleges which do not require a matriculation examination, finds all the colleges of the State substantially, and by previous arrangement and announcement, complying with the condition. There could of course be but one opinion as to what course the local schools would pursue. Among the profession, however, there is a good deal of speculation as to how schools outside of the State will treat the rule. A graduate of a college not requiring the examination, coming into the State to practice, hereafter will be obliged, before securing his license, to undergo an examination by the State Board of Health. Now, will the large schools east of Illinois, many of whose graduates annually locate in the State, allow their alumni to be put to this disadvantage and inconvenience? It certainly will lessen their classes to some degree if it is known that this sort of an embarrassment is to be affixed to graduates who may or might desire to settle in any one of the large and growing States of the West. Candidates for a degree will not like, by attending a particular college, to invite such an embarrassment. Colleges wishing to avoid this must conform to the rule, or, by making a test case in court, cause, if they can, the rule to be set aside. There are not wanting men who believe that if a test case was made the Board would find itself without authority to establish such conditions. Others believe the Board has not exceeded its authority. There has been some gossip in professional circles about the prospect of the present Legislature abolishing the Board altogether; but this is not likely to occur, as there is a popular belief that it has driven large numbers of quacks out of the State, and as the Governor, in his annual message, has commended the work of the Board in a most flattering manner.

— The friends of Dr. E. Fletcher Ingals will be glad to know that he has been made a professor of laryngology in Rush College.

— The St. Luke's Hospital is to have its new building completed next summer or autumn. This will be a permanent structure of brick, and will greatly enlarge its capacity. It will front on Michigan Avenue, which is now under the control of the South Park Commissioners, and is a permanent boulevard leading to the Parks. The building will reach entirely across the block, and front also, as at present, on Indiana Avenue. It will be provided with all the modern improvements in hospital fitting, including a snug operating amphitheatre, where its staff expect to give regular clinics. This is one of the most useful and commendable hospitals in the city.

— The Illinois Training School for Nurses is having built, near Cook County Hospital, a Home for a residence for its nurses. The necessary funds have been contributed by the public. The school has been very successful at the County Hospital. Indeed, this is about the only part of the hospital organization of which there has been no complaint from any one.

Miscellany.

ANNUAL REPORTS OF THE STANDING COMMITTEES OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

The following committee reports were made at the annual meeting of the College of Physicians, Philadelphia, January 3d last.

The Publication Committee reported a larger contribution of interesting papers to the forthcoming volume of *Transactions* than has ever been made before.

The Library Committee reported that the library contains 23,653 volumes, of which 15,901 belong to the general library, 6208 to the "Lewis Library," and 1544 are duplicates. During the year 1882, the additions to the library amounted to 1234 volumes. A complete card catalogue of authors and subjects has been made of the "Lewis Library," and that of the general library is well advanced. The library of the late Dr. H. Lenox Hodge, containing 1665 volumes, is deposited with the college in trust. The constant and rapid growth of the library obliged the committee to urge a liberal appropriation for the extension of the shelf-room and the payment of the librarian and the assistant charged with preparing the catalogue. Next to the library of the Surgeon-General's office, that of the College of Physicians of Philadelphia is the largest medical library in the United States.

The Mütter Museum Committee urged the necessity of providing increased accommodation for the museum.

During the last year a large number of valuable preparations have been received: —

From Framond, of Paris, 100 wax specimens illustrating diseases of the eye; 22 preparations (natural) showing dentition from early life to old age; 20 casts of female pelves taken from noted cases of deformity; 1 large wax model of thoracic duct and lymphatics; 2 rubber models of pelvic viscera, male and female; 1 wax preparation of confluent small-pox; 1 wax preparation of syphilitic disease of scalp; 4 natural lymphatic injections of foot, hand, and stomach, also an injection of the canal of Fontana; and 1 adult skeleton, mounted at Royal College of Surgeons, London.

They have also received from Rohon, of Vienna, six mounted skeletons, illustrating stages in development, with known age and history to each.

They have procured and had mounted the skeleton of a noted case of hydrocephalus.

Also through Dr. Hays, the committee obtained the body of a cyclops which was dissected, and reported upon by Drs. R. Meade Smith and A. J. Parker.[1] A good plaster cast and two drawings were made from it. Other preparations of importance were also received.

The Committee on the Directory for Nurses reported that the Directory was opened May 15, 1882. Rooms for the secretary were fitted up, and the telephone and telegraph introduced. Circulars and blanks to the number of 8500 were prepared and widely distributed to all the physicians in Pennsylvania, New Jersey, and Delaware, and to the summer hotels within easy reach of this city. The coöperation of the two training-schools for nurses (the oldest two in the country) was secured, and the medical and daily press of the city showed a very friendly spirit, and assisted us in making the Directory known. The following are the rates of charge adopted: For information leading to the engagement of a nurse between 7 A. M. and 6 P. M., one dollar; between 6 P. M. and 10 P. M., two dollars; between 10 P. M. and 6 A. M., three dollars; for wet nurses, uncertified, five dollars; for wet nurses, certified (after careful medical examination of mother and child), ten dollars; for finding and sending a nurse, an additional dollar. Up to December 1 the number of applications for registration has been 296. Fully registered, 214; approved and awaiting registration, 17; disapproved, 19; stricken from roll for grave faults or defects, 2. Of the registered nurses there are 26 males and 187 females; 35 graduates of training-schools; 165 non-graduates; manipulators, male and female, 11; cuppers and leechers, 3.

The number of calls for nurses has been 342 during the seven months, an average of about 50 a month. We have furnished as many as 8 in a day, and 5 to a single family. One of the most important results achieved through the Directory is the promptness with which calls to grave emergencies are met. Another and very marked advantage of the Directory is, that we not only give information as to disengaged nurses, but, if desired, will find and send them to the patient. This saving of time and trouble to applicants is often very desirable, and the small extra fee charged for the service (one dollar) is very gladly paid. Especially is this service valuable to patients out of the city.

We have also undertaken to supply wet nurses. We have had 35 applications, but have only been able to supply 13, and we beg especial attention to this fact, in order to obtain many more of this class of nurses.

Our expenses have exceeded our income by a very large amount, and had it not been for the generous contributions of many friends, chiefly through Mrs. Weir Mitchell, the Directory could not have been placed on a firm foundation at its start. Next year it s hoped that it will be about self-supporting.

— Report hath it that Charles Reade, being asked by "Ouida" to suggest a suitable name for her dog, advised that he be called Tonic, because he was a mixture of bark, steal, and whine.

[1] See the American Journal of the Medical Sciences for July, 1882.

ARTIFICIAL FEEDING FOR INFANTS.

IN a clinical lecture delivered at the Pennsylvania Hospital by Dr. Arthur V. Meigs, and reported in the *Medical News*, a formula is given for an artificial milk-food, constructed in accordance with the author's own analysis of human milk. It contains the same elements that are found in human milk, and, it is claimed, in more nearly the same proportions than any other food heretofore recommended. It consists of two parts of cream, one of milk, two of lime water, and three parts of a solution of milk sugar of the strength of seventeen and three fourths drachms to the pint of water. The milk to be used should be good ordinary cow's milk, and not the very rich milk of Jersey or other high-bred stock, and the cream in the same way should be such as is usually sold in cities, and not too rich, containing about sixteen or seventeen per cent. of fat. The quantity of this food taken by a newborn infant should be two or three fluid ounces every two hours, and if it thrives, it will soon take as much as a gill every two hours.

The best way to prepare and use this food is to order five or six packages of milk sugar, containing seventeen and three fourths drachms each; the contents of one of these to be dissolved in a pint of water, and each time the child is to be fed, let there be mixed together, and then warmed, three tablespoonfuls of the sugar solution, two of lime water, two of cream, and one of milk. This makes about a gill, and as much of it as the child does not take should be thrown out, and a fresh mixture made for the next feeding. The solution of sugar should be kept in a cool place, and at once thrown away if it sours, as occurs if kept more than a day or two in warm weather. The dry sugar keeps indefinitely, and is easily dissolved in warm water. A pint bottle should be kept for the purpose of containing the solution, to serve also as a measure of the quantity of water to be used with each package dissolved, and also to save further measuring.

The preference of Dr. Meigs for cream as a basis of the food is due to the fact that if milk is used there is too much casein, though the fat is in the right proportion, and if condensed milk is employed the casein is right, but there is too little fat. It will be observed that, as the fat and casein bear the same relative proportion to each other as they do in pure cow's milk, it would be impossible to dilute or mix it in such a way as to have the elements in the proportions contained in human milk, for by increasing the quantity of condensed milk used, to get more fat, we add at the same time too large an amount of casein.

— The *Medical News* has been investigating the honesty of manufacturers of quinine pills and finds that of seven of them only two give good weight. The others show a deficit in the amount of the drug to be found in an alleged "two-grain pill" varying from five to twenty per cent. With commendable frankness the paper publishes the names of the manufacturers with the results of the quantitative analysis. In the prices of these different specimens there was a wide variation — the range being from $1.70 to $2.75 per hundred. The latter price was that of the most fraudulent article. It is but fair to say that the manufacturers reflected upon have since published analyses which they claim show the honesty of their work.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 20, 1883.

Deaths reported 2841 (no report from Chicago): under five years of age 1002: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 650, consumption 434, lung diseases 383, diphtheria and croup 208, small-pox 127, scarlet fever 97, typhoid fever 70, diarrhœal diseases 44, erysipelas 21, measles 20, malarial fevers 19, cerebro-spinal meningitis 18, whooping-cough 17, puerperal fever nine. From *typhoid fever*, Philadelphia 12, Providence 10, St. Louis and Pittsburg seven each, New York and New Orleans four each, Boston, Baltimore, Cincinnati, Buffalo, and Charleston three each, Brooklyn two, District of Columbia, Milwaukee, Lowell, Worcester, Fall River, Holyoke, Haverhill, Milford, and Amherst one each. From *diarrhœal diseases*, New Orleans 15, New York 11, Boston, St. Louis, New Haven, and Fall River three each, Buffalo two, Providence and Chelsea one each. From *erysipelas*, Philadelphia five, New York three, Boston, Cincinnati, New Orleans, Pittsburg, and Lowell two each, Milwaukee, Worcester, and Fitchburg one each. From *measles*, New York 11, Boston and Cincinnati three each, New Haven two, Baltimore and Somerville one each. From *malarial fevers*, Brooklyn seven, New Orleans four, New York three, St. Louis and Baltimore two each, Cincinnati one. From *cerebro-spinal meningitis*, New York seven, New Orleans four, Buffalo two, Baltimore, Milwaukee, Lowell, Holyoke, and Woburn one each. From *whooping-cough*, New York four, Cincinnati and Pittsburg two each, Philadelphia, Brooklyn, New Orleans, Providence, New Haven, Lowell, Cambridge, Chicopee, and Woburn one each. From *puerperal fever*, Boston, St. Louis, and Pittsburg two each, Philadelphia, Buffalo, and New Haven one each.

Two hundred and thirty-eight cases of small-pox were reported in Baltimore, Brooklyn one, Pittsburg one; diphtheria 27, scarlet fever 36, typhoid fever six, in Boston; scarlet fever 18 and diphtheria five in Milwaukee.

In 35 cities and towns of Massachusetts, with a population of 966,757 (population of the State 1,783,086), the total death-rate for the week was 19.79 against 21.58 and 19.84, for the previous two weeks.

In the 28 great towns of England and Wales, with an estimated population of 8,620,975, for the week ending January 6th, the death-rate was 21.8. Deaths reported 3598: acute diseases of the respiratory organs (London) 384, whooping-cough 94, scarlet fever 85, measles 82, fever 74, diarrhœa 43, diphtheria 30, small-pox (London five, Newcastle four, Oldham two) 11. The death-rates ranged from 15.2 in Halifax to 30.9 in Liverpool; Bristol 18.6; Newcastle-on-Tyne 19.2; Birmingham 19.9; London 20.5; Sheffield 22.2; Leeds 25.5; Sunderland 26.3; Blackburn 29.8. In Edinburgh 23.4; Glasgow 31.6; Dublin 31.9.

For the week ending December 23d, in 170 German cities and towns, with an estimated population of 8,455,290, the death-rate was 24. Deaths reported 3908: under five years of age 1727; consumption 598, lung diseases 495, diphtheria and croup 190, diarrhœal diseases 118, scarlet fever 81, typhoid fever 73, whooping-cough 51, measles and rötheln 49, small-pox (Breslau and Heilbronn one each) two, typhus fever (Breslau) one. The death-rates ranged from 44.3 in Chemnitz to 11.8 in Würzburg; Königsberg 29.1; Breslau 26.1; Munich 30.2; Dresden 21; Berlin 21.9; Leipzig 21; Hamburg 21.4; Cologne 22; Frankfort a. M. 16.3; Strasburg 25.3.

For the week ending December 30, in 170 German cities and towns, with an estimated population of 8,313,541, the death-rate was 25.1. Deaths reported 4005: under five years of age 1834; consumption 615, lung diseases 489, diphtheria and croup 205, scarlet fever 75, typhoid fever 51, whooping-cough 50, measles and rötheln 42, puerperal fever 16, small-pox (Königsberg, Elbing, and Heilbronn one each) three. The death-rates ranged from 12.5 in Kiel to 38.9 in Munich-Gladbach; Königsberg 33; Breslau 28.5; Munich 28.4; Dresden 23.1; Berlin 24.4; Leip-

zig 21; Hamburg 25.1; Cologne 28.7; Frankfort a. M. 19.7; Strasburg 24.4.

For the week ending December 30th, in the Swiss towns, population 494,390, there were 37 deaths from acute diseases of the respiratory organs, consumption 30, diarrhœal diseases eight, typhoid fever seven, diphtheria and croup five, measles four, whooping-cough two. The death-rates were, at Geneva 16.5; Zurich 14.2; Basle 18.7; Berne 19.6.

For the week ending January 6th, in the Swiss towns, population 494,390, there were 29 deaths from consumption, lung diseases 22, diarrhœal diseases 10, diphtheria and croup eight, typhoid fever four, scarlet fever one, puerperal fever one. The death-rates were, at Geneva 15.4; Zurich 16.4; Basle 15.9; Berne 28.2.

The meteorological record for the week ending January 20th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 19, 1883, TO JANUARY 26, 1883.

HEIZMAN, CHARLES L., captain and assistant surgeon, will be relieved from duty in the Department of the Columbia, and ordered to report to the commanding general, Department of the South, for assignment to duty. Paragraph 10, S. O. 20, A. G. O., January 24, 1883.

KILBOURNE, H. S., captain and assistant surgeon. Leave of absence for one month, with permission to apply for an extension of two months, is granted. S. O. 218, Department of Dakota, December 21, 1882.

SKINNER, JOHN O., captain and assistant surgeon, will report in person, at the expiration of his present leave of absence, to the Surgeon-General for duty in his office. Paragraph 10, S. O. 20, A. G. O., January 24, 1883.

SPENCER, WILLIAM G., captain and assistant surgeon. The leave of absence on surgeon's certificate of disability, granted September 20, 1882, is extended three months on surgeon's certificate of disability. Paragraph 4, S. O. 16, A. G. O., January 19, 1883.

TAYLOR, MARCUS E., captain and assistant surgeon, will report in person, at the expiration of his present leave of absence, to the commanding general, Department of the East, for assignment to duty. Paragraph 10, S. O. 20, A. G. O., January 24, 1883.

WOOD, MARSHALL W., captain and assistant surgeon, will be relieved from duty in the Department of the East, at the expiration of his present leave of absence, and will report in person to the commanding general, Department of the Columbia, for assignment to duty. Paragraph 10, S. O. 20, A. G. O., January 24, 1883.

WYETH, M. C., first lieutenant and assistant surgeon, is relieved from duty at Fort Snelling, and will proceed to Fort Stevenson, D. T., and report to the commanding officer of that post for duty. Paragraph 1, S. O. 15, Department of Dakota, January 18, 1883.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE HOSPITAL SERVICE, OCTOBER 1, 1882, TO DECEMBER 31, 1882.

BAILHACHE, P. H., surgeon. Present detail continued until further orders. October 6, 1882.

To proceed to Louisville, Ky., as inspector. October 13, 1882. Granted leave of absence for thirty days. November 10, 1882.

VANSANT, JOHN, surgeon. Granted leave of absence for twenty days. November 18, 1882.

HUTTON, W. H. H., surgeon. To proceed to Louisville, Ky., and assume charge of the service. October 7 and 14, 1882.

MILLER, T. W., surgeon. To continue at present station until further orders. October 6, 1882.

WYMAN, WALTER. To inspect keepers and crews of the Life Saving Service. October 5, 1882.

LONG, W. H., surgeon. To proceed to Detroit, Mich., and assume charge of the service. October 7 and 14, 1882.

MURRAY, R. D., surgeon. Having returned from service in the yellow fever epidemic in Texas, to report in person to the Surgeon-General, M. H. S. December 4, 1882.

Granted leave of absence until February 28, 1883. December 19, 1882.

FESSENDEN, C. S. D., surgeon. To proceed to St. Louis, Mo., and assume charge of the service. October 7, 1882.

PURVIANCE, GEORGE, surgeon. To inspect keepers and crews of the Life Saving Service. October 21, 1882.

SAWTELLE, H. W., surgeon. To proceed to New York, N. Y., and assume charge of the service. October 7, 1882.

AUSTIN, H. W., surgeon. To inspect keepers and crews of the Life Saving Service. October 5, 1882.

FISHER, J. C., passed assistant surgeon. Present detail continued until further orders. October 6, 1882.

To proceed to Alexandria, Va., as inspector. October 21, 1882.

THE SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY will meet at 19 Boylston Place, on Wednesday, February 7th, at 7.45 P. M. The following papers will be presented: Wound of Perinæum extending into Vagina, Compound Separation of Symphysis Pubis with Prolapse of Bladder; Recovery, Dr. C. D. Homans. Deep Abscess of the Thigh, Dr. D. W. Cheever. Dislocation of the Sternal Extremity of the Clavicle, with Dislocation of the first and second Costal Cartilages, Dr. A. N. Blodgett. Dr. W. J. Otis will show a New Tracheotomy Instrument. H. C. HAVEN, *Secretary.*

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday, February 5, 1883, at eight o'clock P. M. Reader, Dr. Frederick C. Shattuck. Subject, Two Cases in Practice: (*a*) A Case of Fatal Obscure Nervous Disease. (*b*) A Case of Empyema evacuating itself through the Lung, with Subsequent Recovery. Dr. J. S. Greene will report a Case of Obscure and Rapidly Fatal Disease attended by Extensive Painful Tumefaction of the Skin. C. M. JONES, *Secretary.*

Lectures.

OPENING LECTURE ON DISEASES OF CHILDREN, AT THE POST-GRADUATE MEDICAL SCHOOL, NEW YORK.

BY MARY PUTNAM JACOBI, M. D.

DEFINITION. — At the outset of this course, which I am to have the honor of delivering to you, I deem it appropriate to define the circumstances which serve to specialize diseases of children in the wide field of human pathology.

Setting aside certain superficial practical considerations, we may come at once to the consideration which constitutes the basis of this specialization. It is the fact that the child represents an organism in a state of continuously progressive development. The details of this development may be classified into four groups, namely: —

(A.) Those concerning the adaptation of the organism to a succession of different media, and to a succession of changes in its relations to surrounding objects.

(B.) Those concerned in an increase of bulk.

(C.) In an elaboration of structure.

(D.) In an evolution of function.

Transition to Different Media. — The successive adaptations are necessitated by a series of transitions: —

(1.) From the placental to pulmonary respiration.

(2.) From vascular or imbibition nutrition to nutrition through processes of ingestion and digestion.

(3.) From the recumbent to the erect position.

(4.) From passive nervous and reflex muscular action to voluntary movement, mental action, and locomotion.

Rapidity of Change. — The rapidity and intensity of the changes through which the infantile organism passes both increase in proportion as we approach the birth point, and diminish as we recede from it. Thus the first hour, first day, first month, first year, may each be considered as distinct periods, covering changes of such magnitude as are effected in no other hour, day, month or year of existence. For in the first hour of the birth of the child, pulmonary respiration is established, involving a complete alteration of the intra-cardiac circulation together with extensive changes in that of the liver and entire abdomen. The arterial blood pressure becomes superior to the venous: the oxygenation of the blood passes from a minimum to a maximum; the functions of the heat-regulating apparatus, hitherto rendered unnecessary by a medium of constant temperature, are now initiated. During the first day the functions of the alimentary canal are established; the prehensile capacity of the mouth; primary digestion in the stomach and intestines; absorption and excretion. Extensive desquamation begins over the entire tegumentary surface, — in the alimentary canal of epithelium, on the skin of epidermis. This desquamation continues during several days of the first month, and accompanies the first effort of secreting activity on the part of the buccal, peptic, and intestinal glands on the inner, and of the sweat glands on the outer, tegument. The salivary and pancreatic glands do not elaborate effective secretions until after the close of the first month. During its first half, however, occurs the fall of the cord and healing of the umbilical wound; the adjustment of equilibrium in the hepatic circulation; the emptying the middle ear of accumulated epithelium, by successive efforts of deglutition; the habitual working of the heat regulating apparatus; the development of the psycho-motor centres in the brain. The latter, according to the experiments of Soltman, become for the first time responsive to faradic excitation on the tenth day after birth in puppies. It is probable with the much slower rate of development of the human young that in them these centres become excitable much later.

During the first year not only these but all the ganglionic centres in the cerebro-spinal axis become elaborated in structure. The special senses are trained, and the centres in which their nerves terminate become habituated to decompose the impressions these transmit to them. The power of voluntary movement is acquired; the growth of muscles, of the bony skeleton, and of the teeth in their alveolar cavities constitute prominent phenomena of the physiological life. The heart doubles in size (from a capacity of 20 cc. at birth to 40 cc.); the lungs treble themselves. (Beneke.)

The period of the child's life embraced between one and three years is marked by the completed eruption of the teeth; by change in diet, and hence in process of digestion; and by the further evolution of nerve centres connected with the acquisition of speech, the awakening of intelligence, and the attained ability for station and locomotion. The latter again implies continued progress in the development of the musculo-osseous system.

Between the age of three and seven years begin the social relations of the child; from seven to fourteen, and especially in the latter years of this period, the growth of the body, and particularly of some of its organs, becomes again extremely active, and preparation begins for the development and functions of the reproductive organs.

Correlative with each period thus demarkated, we find a preponderating liability to some special morbid condition. The correlation is rarely exclusive; few diseases are absolutely limited to any one period of life; but there are preponderances indicating an approximate limitation. An absolute limitation exists in regard to the morbid conditions associated with congenital malformations; and also in regard to the group of diseases known as those of the new born. The former are necessarily present at birth, and discoverable in the first hour of existence. The latter arise from possible accidents of parturition, or during the successive movements of transition effected during the first hour, day, or month. Thus, in the first hour we may encounter the formidable accidents of asphyxia, and arachnoid hæmorrhage, and the far lesser danger of subperiosteal cranial hæmorrhage constituting cephalatoma, — all dependent on abnormal pressure received by the child during the process of parturition. It is at the same moment that the fatal apnœa of diaphragmatic hernia is also, if ever, observed.

During the first day, or even the first two or three days, secondary morbid processes consecutive to an asphyxia or apoplexy of parturition are liable to appear. The infant whose respiration has been established after laborious efforts may develop pneumonia in consequence of intrauterine aspiration of foreign matters into the air passages. This is a "Schluck-Pneumonie," analogous to that caused by section of the vagi nerves, and paralysis of the glottis. A portion of the lungs may remain unexpanded in fœtal atelectasis, or subsequent portions may collapse from weakness of the inspiratory efforts. Such atelectasis is a not unfrequent

accompaniment of meningeal hæmorrhage. The latter again, initiated during the birth process, may continue to extend, not proving fatal till several days after birth. The cerebral hæmorrhage may of itself occasion no characteristic symptoms, but by extension along the medulla, or into the spinal membranes, may determine tetaniform convulsions.

Paralyses rarely or never arise from arachnoid hæmorrhage, but often coincide with them as a result of the same cause. The cadaver that I here show to you is that of a child who was found on the first day to be paralyzed in the right arm, and on the second day began to exhibit symptoms of arachnoid hæmorrhage over the left cerebral hemisphere. But the paralysis was due to compression of the right brachial plexus.

Meningeal hæmorrhage is not always the result of a parturient traumatism. It may be the expression of a puerperal infection; its symptoms so dominate the rest, that they are overlooked. Thus, the infective process tends, in the new born as elsewhere, to cause fever; but this tendency may be so checked by the hæmorrhage that the temperature falls even below normal.

Instead of paralysis from compression of nerves, the child may suffer fracture in one or more limbs. The baby I now show you was born with fracture of the right humerus, and also of the right femur. The mother was attended by a German midwife who summoned a physician, and both together applied some kind of splint to each injured limb. But the adjustment was so imperfect, that to-day, two weeks later, the fragments of the humerus are still freely movable on each other, and the fragments of the femur have united at an obtuse angle.

A prominent accident of the first day or days of infantile life is umbilical hæmorrhage. Certain English authors speak of this accident as one easily controlled. This is, however, only the case when it is dependent on a local process; but when, as is much more frequent, the hæmorrhage is the expression of constitutional disease, it is usually fatal. Under this microscope are slides representing sections from various tissues in such a case, where the hæmorrhage began two hours after birth, repeated itself frequently, and proved fatal in ten hours. It depended on a generalized fatty degeneration of the blood-vessels.

This fatty degeneration may begin in fœtal life, and be associated with acute fatty atrophy of the liver (Hecker and Buhl); or it may occur as an element of the complex process of the puerperal infection of the new born. This disease again may begin before birth, and even run its entire course in utero, the child being born dead with lesions of general peritonitis. After birth the same pyæmic process may be, now the cause, now the result of inflammations of the navel, or of the umbilical vessels.

Pyæmia and the acute fatty atrophy or Buhl's disease are both accompanied by severe icterus; a milder form of jaundice is extremely common during the first week of life, the well-known icterus neonatorum. The semiphysiological character of this symptom invests it with more interest than it could derive from its clinical importance. By some authorities it is considered only apparent, and to be dependent on the flushing of the skin during the process of the establishment of respiration, and the desquamation of the cuticle. By others again it is associated with the changes in the hepatic circulation. The tension is said to be so lowered in the hepatic veins, after closure of the umbilical vein, that bile passes freely into them from the biliary capillaries. Finally, the icterus has been attributed to destruction of the blood corpuscles, and this hypothesis again divides itself between two theories: according to the first, the destruction takes place within the blood-vessels at large, and the color of the skin depends on the accumulation of hæmatoidin, chemically identical with bilirubin. A much more tenable theory is based on the fact, recently demonstrated, that icterus is associated with an excess of the denutrition, — of the loss of weight, — normal to the first days of life, before the digestive processes are able to compensate the processes of waste. The blood corpuscles are attacked, in common with other albuminoid substances are destroyed in the liver, and their coloring matter occasions the formation of an excess of bile.

On escaping from the sphere of parturient accidents or diseases, and the time at which the various malformations may be properly studied, the child passes during the second half of the first month into a second region of liability, where disease depends on the imperfect function of organs. After the establishment of pulmonary respiration, the initiation of extra-uterine nutrition involves a series of processes, whose equilibrium is very easily overthrown. During the period of normal insufficiency of the digestion the metamorphosis of albuminoid substances — of which part is derived from the stored albumen of the tissues — is also incomplete. Hence, together with the formation of a large amount of urea, — also occurs the formation of an excess of uric acid. This may accumulate in the canaliculi of the kidney, constituting the renal infarctus of the new born; a lesion constantly discovered after death from malnutrition during the first weeks of life.[1]

A still greater degree of nutritive failure involves encroachment upon the fixed albumen of the tissues, and the child visibly emaciates. The imperfect digestion is indicated by acid fermentations of food, with consequent colic, vomiting, diarrhœa; or, as a result of the continued irritation of the digestive mucosa, catarrhal inflammation sets in. The growth of thrush (oidicum albicans) is facilitated by the desquamation of epithelium normal to the period. The ultimate result of these gastro-intestinal disorders, if unchecked, is a state of profound and pitiful denutrition, variously known as marasmus, atrophy, or athropsia.

The tendency to gastro-intestinal disease persists throughout the first year. A similar liability exists towards disease of the respiratory apparatus, and for the same reason in both, namely, the novelty of function. This contrasts with the immunity from disease of such organs as the heart, liver, and kidneys, whose functions have been exercised during several months of fœtal life. These organs seem to become liable to disease as they wear out from long use, not as they enter upon their functions.

During the first year two constitutional diseases first show themselves, hereditary syphilis in the first quarter, rachitis in the second quarter or half. Both depend on perversions of nutrition, — on the one hand, through the influence of a specific virus; on the other, through digestive failure and anæmia.

The three remaining periods of morbid liability can only be defined approximately. Thus, from the age of one to three, there is a greater tendency to certain

[1] Virchow supposed that the renal infarctus is normal to the new born. But this hypothesis has been rendered improbable.

forms of nervous disease. The maximum liability to meningitis is at two years. (Rilliet and Barthez.) Convulsions are associated both with processes of dentition (through the medium of a coexisting rachitis) and with digestive disorders, the latter frequent from the change of diet at weaning. The evolution of function in the nerve centres at this period of life constitutes a predisposition to nervous disorder. Scrofulous malnutrition, tuberculosis may be assigned to this same period, because, on the whole, it is then that they most frequently manifest themselves for the first time.

The fifth period, embracing the four years from three to seven, is especially characterized by the liability to infectious diseases, as diphtheria, the eruptive fevers, pertussis. This tendency is evidently associated with and partly caused by the widening social relations of the child, by which he is much more easily and frequently brought into contact with sources of infection.

Finally, the sixth period, extending from seven to fourteen, continues the morbid tendencies of the last two; shows a greater tendency to diseases of the osseous system; exhibits more distinctly the marks of constitutional anæmia, and develops the liabilities to rheumatism, and to certain neuroses, for example, chorea, epilepsy, hysteria.

FRANKLINISM, OR ATMOSPHERIC ELECTRICITY, AS A REMEDY.[1]

BY A. C. GARRATT, M. D.

The old-fashioned friction electrical machine, consisting of a glass globe or cylinder, or later of a single glass plate, has recently been so wonderfully improved and enlarged as to be in practice a comparatively new apparatus; more powerful and efficient, more certain and uniform in action at all times, and affording a wider use of static electricity in medicine. The friction machine, as is well known, would not work in stormy weather, nor when the atmosphere was damp, humid, or *nil*, unless the room and machine were kept warm and dry by fire, and sometimes not then. When it did work it gave sparks of only one or two inches in length, at best. To make up for this it was formerly the practice to accumulate the electricity in Leyden jars, and then apply it by shocks. But all this is in the past.

The new large sized *static*-induction machine — I refer to the improved Holtz or Toepler-Holtz — is found to work at all times, in any weather, and with or without fire in the room. We can now at any moment get either a stream of fine little sparks that are numerous, rapid, and mild, or graduated stronger and longer sparks, from one to seven or even ten inches in length, repeated every few seconds or more often, for any length of time. Or they can be increased so as to resemble flashes of lightning attended with reports like those of a pistol. Yet this surprising power, made so manifest in this form from the machine, can be completely controlled and so as to be to the patient a comfortable, general electrization, formerly called *the electric air-bath*. Thus we can now apply long and heavy sparks, as in cramps, palsy, or anæsthesia; or sustain the patient enveloped from head to feet in an electrical potential, more or less high, for a longer or shorter time, as a general nerve tonic, and all the while as exhilarating and refreshing to the person as sunshine in winter, or a cool breeze in the heat of summer; and what is more important, the good effect of this is lasting. To imagine that this new machine, of seven glass plates twenty-five to thirty inches in diameter, is like the old friction machine, would be like comparing a powerful and beautiful steam engine to a tea-kettle.

With this immense advantage the medical use of atmospheric electricity is already revived with great success, in Germany, by Professor Clemens, and others; in Austria, by Professor Scwauda; and in France, by Professor Charcot, especially at his clinic in Paris, where he is aided by Dr. Vigouroux. This static-induction apparatus of *many plates and large size* must hereafter hold a prominent place for providing this most natural form of electricity in all more complete and thoroughly efficient electro-therapeutics. Not by any means supplanting the invaluable primary or secondary apparatus, but supplementing them at office or in hospital, with a greater efficiency of medical electricity when thus in ample quantity, and possessed of the peculiar statical quality, such as those cannot provide. But I insist, it is only the *large*-sized machines that are uniformly able to fulfill satisfactory results, and these are expensive. A machine of this kind having only two plates, if of large diameter, will produce quite long but *thin* sparks of relatively high tension, while the addition to the machine of several more plates, of like diameter, will increase its ability to produce greater quantity of electricity, hence thicker sparks when required, and ability to charge and sustain the insulating chairs and table with a high potential in all kinds of weather, which is a point of first importance.

This "improved" Holtz machine is now not only being used in Paris and Berlin, in Vienna and London, but is already in use here in Boston, by myself; in New York, by W. J. Morton, Professor Hammond, and others; in Philadelphia, by Professors Blackwood and Bartholow, and is destined to be found hereafter, at least, in all large cities, medical centres, and in hospitals, in this country. The ordinary medium or smaller sizes and few plates of the Holtz, or Toepler-Holtz machines, have for some time been placed among the philosophical apparatus in many of our colleges. But are medical teachers and practitioners generally aware of the positively nerve correcting power of "static electricity," when provided, as now, in ample quantity, at all times, and yet under delicate and complete control for efficiency and absolute safety?

The name electricity, as it relates to therapeutics, has now become merely a generic or general term. We cannot but see the increasing necessity of more definitely designating its particular form or classification, and the precise mode of application in every case, whenever it is referred to in regard to treatment, as in reporting cases. It is not enough to state simply that electricity was applied. But who applied it, from what instrument or source, and how. These must appear, or the report is of no value. However, this paper is written not with the intention of covering this field, nor even any division of it, but to recall attention to its methodic use, and as an example of what has been and can be effected, often most promptly in some difficult cases, by means of this improved franklinism.

Although perfectly well known to many, we need to restate and familiarize the fact, that more than heretofore we are to recognize three distinct kinds of

[1] Read October 28th before the Suffolk District Medical Society.

electricity for remedial uses, provided from three principal sources, by three distinct classes of apparatus, each producing electricity with very different and important characteristics peculiar to itself, which can be again modified so as to produce certain effects that cannot be replaced by any other. For it is fundamental that though in its nature electricity is always the same, yet its effects and ultimate results are decidedly varied, according to its source, form, and method of application. Hereafter it may be convenient for us to recognize the following classes: —

First Class: "Static Electricity," the oldest form known, is derived from the atmosphere only, and when employed as a remedy is termed franklinism.

Second Class: "Galvanic Electricity," and the voltaic (for these two may here be reckoned together as the same, each being produced by chemical action, as from moist metal plates in the voltaic pile, or wet metal plates in the cell of the galvanic battery, it being of the same nature and producing the same effects under like conditions) is known as the "primary" current, whether it is employed as a constant, or continuous, or interrupted current, and as a remedy it is or should be invariably termed galvanism.

Third Class: "Induced Electricity," which embraces all those phases of the familiar "secondary," interrupted, and usually *to and fro currents;* induced and greatly increased in certain physiological effects by means of a helix or coils of wire, either from the primary current alone, or from the primary with magnetism, or from magnetism alone, and of late from the static, each of which should be exactly and invariably expressed, as either the static-induced, or as electro-magnetism, or as magneto-electricity, when produced by a revolving armature in the presence of a magnet; all or either of these as the *induced* or "secondary," and when employed as a remedy the general term is faradism.

It is in regard to the greatly improved apparatus of the first class only, and the excellent effects of the electricity it provides, that attracts our particular attention at this time. Having had considerable and diversified experience of late with static electricity from the improved Holtz machine, the writer is impressed more than ever with the great (and in many cases of a certain class of diseases the superior) merits of the *static* quality and quantity of electricity, because of the decidedly good and quick work it can do in many difficult cases; so that he wishes all physicians to realize its availability, efficiency, and usefulness.

Considering the present almost general indifference of the profession as a whole to the remedial value of the old form of "static electricity," it recalls the quite general apathy and actual disbelief in some quarters in regard to the safety and power of the primary current or galvanism as a remedy, at the time when the writer first called the attention of this Society to it in 1857, now some twenty-five years ago. We can here appreciate the feelings of my friend Dr. W. J. Morton, when he, fresh from Europe and clinical experience with the static form, first presented this subject before the Academy of Medicine in New York some time ago, and showing the greater facilities of the Holtz machine for providing medical electricity said, "It may at first sight appear an act of temerity to ask attention to a method of treatment now so antiquated. But if, from this point of view, any apology is needed, it is simply that the writer, after careful trials in his own practice of the medical merits of static electricity, feels a natural desire to have others realize its value. Believing, as I do, that in again giving it a trial we shall take a real advanced step in the cure of diseases, I have ventured to bring this subject before you at this time. The invention of Holtz began in 1865, and marked out for modern statical electricity in medicine the possibilities of a new career. In the Holtz machine we have the means capable of furnishing electricity of high tension and in great quantity. By means of the two condensers and the ability of increasing the number of glass wheels, both the tension and the quantity are within the control of the operator. It gives with ease an eight-inch spark and a great *quantity*. Its constructor is Andeiveau, of Paris, while to Dr. Vigouroux, of Professor Charcot's clinic, is due its present adaptation to medical use."

The first medical use of atmospheric electricity, after a time termed "static," dates back one hundred and fifty years. For a long time thereafter the term electricity or electrization covered the whole subject, for that in fact was the whole of it. During a whole generation men obtained electricity from one source only, by one kind of apparatus, and only employed it for remedial purposes, and that by one principal method of application, namely, the shock; sometimes, however, by sparks. The limited power of the friction apparatus no doubt led to that mode of use. For seventy years or more static electricity as a remedy flourished and grew into much favor and use, notwithstanding its capricious action in variable weather, and the crude and cruel method by shocks, as was then generally practiced in England, here, and throughout Europe, even from 1730 to 1800, when the galvanic current was discovered, and the voltaic pile was constructed. Within that first epoch, from 1742 to 1760, Dr. Benjamin Franklin not only experimented successfully to learn something of the nature of this newly developed force, but he also devoted much time to the treatment of many cases of rheumatism, neuralgia, cramps, pains, and palsy, at Philadelphia, and some of them with marked success, using, of course, static electricity, the only form then known. No doubt Dr. Franklin was the first medical electrician in America.

Early in this century, however, the frictional electric machine became gradually neglected or supplanted, for it certainly was much less in use by medical men, possibly from its inconvenience, and partly from the peculiar effects, physiological and remedial, of the galvanic current, obtained from the voltaic pile, or from the new compound battery cells. To my mind it was still more from the disgust physicians must have had for the increasing fashion of hawking about small electrical machines with ample chains and battery of Leyden jars to exhibit at public fairs, shows, or museums, and "shocking" men and women there in platoons and by wholesale to prevent or cure them of consumption, decrepitude, palsy, or rheumatism.

Some years after, in 1832, Faraday appeared with his new-found *induced*, interrupted current, obtained from the galvanic or primary current by induction. Then, soon after, came Dr. Charles Page, of this Commonwealth, with his very ingenious and portable arrangement of helix and cell and automatic vibrator, for providing physicians with this new form of electricity so admirably adapted to certain medical uses. Faraday at once named this the "secondary" current, in contra-distinction to the galvanic or "primary,"

which was its source. Still, in many countries the old static form continued somewhat in professional use even up to twenty-five years ago, if not later. While abroad in 1857 the writer found frictional electricity now and then resorted to in some certain cases by very eminent men in Edinburgh, Paris, and Berlin, in Marseilles and London, but nowhere in this country at that time could we learn that it was employed by any in the regular profession. Todd and Bowman were using it from a large machine in some cases at King's College Hospital, while Golding Bird, Sir William Gull, and Wilks quite frequently referred certain nervous cases to "the electrical room" of Guy's Hospital (which room was kept by a fire constantly warm and dry) for sparks to be given or drawn, or for general insulation and electrifying. At the same time Duchenne, of Boulogne, was demonstrating the superior usefulness of electro-magnetism, while Prof. Robert Remak was advocating at Berlin the surprising and superior remedial power of the primary current by direct applications, and by central galvanization, especially for profound nervous diseases of the head, or central ganglia.

Suffice it to say I was strongly impressed with the peculiar utility of all the three forms, especially the primary current from a compound battery, and the static from a friction machine; they as remedies were then to me new and unique. From what I there saw in the few selected cases of the marked good effects by the static form, I provided myself also with a first-class static machine, which has been more or less in use in my electrical rooms in this city almost to the present time, it being, no doubt, the most worked, exclusively for remedial uses, by a regular physician, of any apparatus of that sort in this country. After all, the friction machine, working only at times, was found to be quite limited in its range of usefulness, because it produced too little for the electric air bath, and we could not increase or accumulate it by Leyden jars for any practical purposes, as I had determined never to use it as a shock. For these and other reasons its occasional good effects could not be reported, nor could the method be recommended to the medical profession.

Notwithstanding, in my own experience during the many years, when other treatments were baffled, and only slight applications were required, positive sparks, an inch or two long, could be elicited from the prime conductor, or negative sparks from the rubber end, so making very efficient localized effects. The former succeeded admirably sometimes in cervical, occipital, and facial neuralgias, also for recurring pains along the back or about the thorax and heart. Recent experience with the Holtz machine while the patient is well insulated on the platform chair, and fully charged generally with positive electricity, the negative sparks being thoroughly *drawn*, proved it a rapid remedy often for chronic muscular, periosteal, or arthritic rheumatism, for cramps in the muscles of the limbs, or of the diaphragm or stomach, or cramps anywhere, especially if it is also directed to the cervical and dorsal spine, also for some of those obstinate "shoulder cases," lumbago, and sciatica, for soreness and stiffness in overworked or strained muscles. Fine positive sparks or electric spray can be directed to the closed eyelids in cases of pains in the eyeballs occurring in delicate persons when caused by fatigue of the ciliary muscles. Longer and stronger sparks are required in local palsy, writer's palsy or cramp, lead palsy, etc.

Does this appear difficult or unsafe? From much experience I am sure it is neither. For example, with the new apparatus and appliances we can give the spray or positive sparks to the temples or about the head for neuralgic headaches. As aid in the treatment of some cases of dim sight and partial amaurosis, as from chronic alcoholism or use of tobacco, or from over-use, the application needs to be reversed and increased, so as to *draw* less frequent and larger sparks from the closed eyes and about them, endeavoring all the while to hold or maintain the eyes, one at a time, in a high positive electrical saturation. This is important. It is accomplished by first placing the patient on the chair, and, while fully charged positively, bringing the gold-pointed electrode connected with the negative main conductor or grounding approximately near the eye, say within three or four inches at first, then as the patient gets used to it bring it nearer. Then replace it, if well borne, by a large ball electrode, with slower turning of the glass wheels, so near only as to allow few sparks, within the bounds of pain and flashes of light, at first, always beginning gently, never working here very painfully nor long, while carefully watching the effects. Repeat these sittings daily or once or twice a week, according to the after-effects brought about. Bearing in mind that though the whole person is enveloped in electricity, yet while the electrode, pointed or ball-shaped, is held near the eye, ear, throat, or any other point of the body, there is accumulated at that point a still higher potential of electricity in the tissues beneath the skin, but of the opposite quality; also that at each disruptive discharge, if of considerable strength, as for palsy of the limbs, the long sparks are believed to either penetrate to the periosteum of the bones, or by induction to disturb the electricity of the tissues to that depth, so producing a radical nutritive change. But to clearly understand this versatile power we are working with, and which is to be so important to physicians, we must further analyze and understand this beautiful apparatus known as the Holtz machine.

ERGOT AND RUPTURED UTERUS.[1]

BY E. M. BUCKINGHAM, M. D.

The patient, under middle age, had had five or six children, one of them still-born; and when first seen by me had been in labor twenty-four hours, under the care of an irregular practitioner. Pains began about eight in the evening and continued until eleven the next forenoon, when the membranes broke. There was no more pain for some four hours, in consequence of which she was given two teaspoons of ergot, — Squibb's fluid extract, I believe. Following this was severe pain, which lasted some time, and then suddenly ceased. This pain had been so severe as to be bitterly complained of several hours afterward.

Later an unsuccessful attempt had been made to deliver by forceps, the woman being very restless and tossing about the bed at the time.

The case was placed in my hands four hours after the administration of ergot.

Examination, both external and internal, caused no contraction and very little pain. The child was in the right occipito-cotyloid position, sutures and fontanelles

[1] Read before the Suffolk District Medical Society, December 11, 1882.

marked by the swelling of the scalp, the os uteri nearly dilated and soft. My finger returned bloody from the examination, and as I finished the patient vomited, immediately after which her pulse was 120, but strong.

It was now seven in the evening. She had had no food since morning, excepting a few spoonfuls of whiskey, and had a few short naps in the previous night. She was given a cupful of hot milk, most of which was retained, and was left to rest for an hour and a quarter, during which she was said to be quiet and with no return of pain.

At the end of that time she seemed to me in good condition, as indeed she did when I first saw her, and it was more than five hours since the ergot had been taken. She was etherized, the bladder emptied of a little bloody urine, and she was examined preparatory to using forceps; but as a hand and the pulseless cord had come down into the vagina I turned instead. Turning was done slowly, but with perfect ease until the head stuck behind the pubic arch. Several attempts were made to extricate, both by the hands alone and with forceps, but without success, until the woman suddenly collapsed. The pulse had been felt, and the countenance watched at intervals throughout, but I saw no warning until the accident happened. Ether, which was now removed, had at no time been given to snoring. She was covered, stimulated with heaters in the bed, and whiskey and laudanum injected subcutaneously, and rallied slightly, but for a short time only. While this rally, which was very slight, lasted, I sent for Dr. G. W. Gay, intending, if he agreed, to perforate the head, as the easiest thing for the mother, but she was dying when he arrived. Ether was injected subcutaneously without effect.

After death forceps were applied by Dr. Gay, and the head brought away by the use of great force. The placenta was removed, and we each felt a tear through the muscular wall of the uterus, to the right of the median line, and near where the placenta had been. This was large enough to insert the hand, and there was a smaller tear in the peritonæum behind it.

Rupture must have occurred either as a result of the forced pains caused by ergot, from the use of forceps, or from turning. I do not believe that it was done during turning, because the uterus was then lax, and there was no resistance until the head was under the pubic arch, and because the accident can be otherwise and I think better explained; neither do I think it was done by the manipulation of the previous attendant, for although trying to apply forceps with the patient tossing about the bed may be dangerous, yet this was after the occurrence of a pretty well recognized symptom of rupture, that is, very severe pain, pain that was complained of hours later by a woman who had borne several children, and which suddenly ceased.

Rupture of the uterus is treated of in most books on midwifery, and the reported cases are many; but reports in which the accident is due solely to the use of ergot are, for obvious reasons, rare. Murphy has collected ten cases of rupture due to ergot, beside one of ergot and a breech presentation, and one of ergot and a slightly deformed pelvis.

One of Collins's cases (Anna Woodward) appears due solely to violent pains, which were not, however, caused by ergot. The uterus ruptured in the sixth labor, she recovered and in the eighth had again very violent pains.

One would naturally suppose that so severe an accident would be followed by shock, sufficient to show that something was wrong; but in this case I was rather surprised that so long a labor, with little sleep and without food, should have left her in so good condition; and in the reported cases the shock seems to vary very much in degree and in length, or to be altogether absent.

I suppose that the emptying the uterus in this case either increased the tear or caused hæmorrhage into the peritonæum, either of which would explain the sudden failure.

RECENT PROGRESS IN DISEASES OF CHILDREN.

BY T. M. ROTCH, M. D.

ACUTE MILK POISONING.[1]

DR. E. F. BRUSH, physician to the New York Infant Asylum, appears to have had unusual opportunities for observing the effects of abnormal milk on infants, and his remarks on this subject are significant of how often the real cause of an infantile diarrhœa may be overlooked, and the facts which he brings forward are valuable in that they may direct the attention of the general practitioner to this class of cases, which presents a wide field for investigation.

Dr. Brush says: "Our cows are secreting milk abnormally, and I use the word 'secreting' in the sense we understand it physiologically. We keep up the activity of the mammary gland from parturition to parturition, this is through heat and pregnancy. This process being carried on through generations in the bovine race has resulted in the mammary becoming an excretory gland. When a milking cow eats food which would cause diarrhœa in other animals she simply gives more milk, and the bowels are seldom much disturbed, but the poison is conveyed to the infant. J. P. Norton, professor of scientific agriculture at Yale College, states 'that all the effects of poisoning may be produced by the milk without the cows being apparently affected by the pasture.' The conditions that render milk poisonous are: —

"First: Feeding. The sudden change from the dry food of winter to the full flush of grass, picking up green fruit, eating brewers' grains, which make the milk more albuminous, and therefore more prone to putrefaction with the increase of summer temperatures, eating poisonous weeds, and drinking poisonous stagnant waters.

"Second: Treatment. Dairy farmers endeavor to have their cows calve in the spring-time, when the grass is plentiful, because then the feeding is cheapest, and the amount of milk to be got is greater. Now, if a cow calves in May she is usually in heat again in forty days, this brings the period to the last of June or the beginning of July. If she were allowed to become pregnant then her calving time would occur too early next year to get the flush of milk at grass time. Consequently she is allowed to worry, and quite often excite, the whole herd. This condition affects milk so perniciously that cheese makers exclude it from the factory; the odor is sometimes perceptibly putrid, and almost always easy to detect when the milk is heated in a water bath. Again, the milk is affected when the cow takes the bull. I have found by observation of my own cows that the milk following the act is always decidedly acid. In the subsequent pregnancy there

[1] Medical Record, October 14, 1882.

can be no doubt that the nutritive quality of the milk is lowered. Last but not least in the treatment of milch cows as a cause of poisonous milk is the cruel abuse to which they are subjected.

"Third: Diseases which are too numerous to mention here in detail. I will here, however, record my observations on a very common disease in milch cows, common because it occurs frequently, and receives little or no treatment, and yet the milk thus affected finds its way to the market to convey poison to the children. Last winter I made an experiment on one of my own cows. I bruised one quarter of the udder, thus producing traumatic garget. This often occurs in pastures by the cow striking the udder against stumps, etc. I found the milk from the gland in the affected quarter for a number of days stringy and lumpy, but always alkaline. The milk from three unaffected quarters presented no abnormal appearance, but while the traumatic condition existed was always decidedly acid. When this condition had lasted for four days I gave to one of my own children, aged sixteen months, about four ounces of this acid, normal-appearing milk. This was at five o'clock in the evening. The child fell asleep, but was awakened in two hours, crying apparently with stomach-ache. She was kept awake until past midnight, and a large quantity of acid was voided per rectum. The next day the bowels were slightly disturbed."

Dr. Brush also cites cases where maltreatment of a bulling cow apparently so affected her milk as to cause serious symptoms of vomiting and diarrhœa; he also speaks of the cases of poisoning which arose in the Alleghany districts some years ago from the milk of cows where poisonous herbage was afterwards discovered in the pasture. The writer of this report saw, during the past summer, what he supposed to be a case of acute milk poisoning, though no analysis was made of the milk. The case was that of a strong, healthy boy, four years of age, who had for over a month been thriving on the milk of one cow, the cow having unusually good pasturage, and being under close supervision. The cow began to bull in the night, and on the following morning the child was seized, after drinking the morning's milk, with vomiting and diarrhœa, which immediately ceased when the milk was changed for a few days. No other cause for the attack could be discovered beyond some supposed chemical change in the milk, transient in character, and lasting while the cow was in heat.

THE RELATION OF THE RED AND WHITE CORPUSCLES IN INFANCY.[1]

Prof. R. Demme found that it was much more difficult to determine the amount of corpuscles, especially of white corpuscles, in infant's blood than in the blood of adults. This was because of the large quantity of free nuclei present, amounting in the blood of a child two to eight days old to from 350,000 to 420,000 in one kilogramme of blood. Beside this the blood of sucklings, toward the end of digestion, contains a great number of dust-like bodies, which render the serum cloudy, and which are in a sort of transformation condition to genuine red blood corpuscles, and are difficult to exclude from an enumeration. Demme's experiments have been carefully carried out, and give about the following results: —

For every one white corpuscle there are

	A	B
At the age of	12 to 72 hours,	135 red corpuscles.
At the age of	4 to 7 days,	157 red corpuscles.
At the age of	8 to 14 days,	165 red corpuscles.
At the age of	15 to 30 days,	173 red corpuscles.
At the age of	31 to 60 days,	180 red corpuscles.
At the age of	61 to 90 days,	185 red corpuscles.
At the age of	91 to 120 days,	191 red corpuscles.
At the age of	121 to 150 days,	210 red corpuscles.

The column under A is for cases nourished exclusively by the mother's breast, that under B for cases nourished by cow's milk. The counting was done two and a half to three hours after feeding.

To a given quantity of blood there are more white corpuscles in infancy than in adult life, and the absolute number of all blood corpuscles is greater in the first days of life than in adults, the blood also is richer in hæmoglobin, which, however, decreases after about two weeks. Demme also found between the fifteenth and twentieth days: —

Before the first meal . . .	1 white to 150 red corpuscles.
25 to 30 minutes after the first meal	1 white to 155 red corpuscles.
3 hours after the first meal . .	1 white to 145 red corpuscles.
25 to 30 minutes after the second meal	1 white to 100 red corpuscles.
3 hours after the second meal .	1 white to 142 red corpuscles.
25 to 30 minutes after the third meal	1 white to 92 red corpuscles.
3 hours after the third meal . .	1 white to 158 red corpuscles.

These relations were disturbed, and there was an increased proportion of white corpuscles, when there was indigestion or constitutional disease.

INCONTINENCE OF FÆCES.[2]

Dr. George B. Fowler reports the following two cases, interesting from the comparative rareness of the affection, and from the apparent speedy recovery under treatment. No 1, a boy of mushroom growth and hothouse culture, aged seven years, began before breakfast every day with an hour of Spanish, and until three P. M. was unceasingly occupied with French, German, music, and the ordinary school curriculum. This policy, initiated four years previously, the pressure being gradually increased, had been maintained almost without interruption. The child had consequently developed into a sort of loaded phonograph, capable of startling automatic expressions, which gave the ambitious father great hope and comfort, until finally the sphincter ani became affected. When this occurrence first took place the child was sharply reprimanded, but the accident repeating itself in the beginning two or three times weekly, and later about once a day, he was severely flogged on many occasions, deprived of liberty, luxuries, etc., yet without avail. Dr. Fowler failed to find any spinal lesion, and the rectum was to digital exploration perfectly normal. The sphincter was tight, grasped the finger with the usual firmness, and there were no sources of irritation about the anus. A cessation of the punishment and release from books was ordered, and ten drops of Squibb's fluid extract of ergot given three times daily, and in about three weeks the involuntary discharges became gradually less frequent, and finally ceased altogether. No. 2, a girl thirteen years old, had had incontinence of fæces from the time that she was an infant. When remonstrated with she would be deeply affected, and declare her inability either to explain or avoid the accident. Electricity had been applied, without effect, generally and locally. The patient was tall and slim, with a pale, expressionless countenance; the flesh was cool and flabby, the sclerotics pearly white, and her motions

[1] Jahrb. für Kinderh. American Journal of Obstetrics, October, 1882.

[2] American Journal of Obstetrics, October, 1882.

listless. Examination of the sphincter ani gave unmistakable evidence of relaxation of its fibres, for although to a casual observer the anal outlet was sufficiently closed, yet there was an absence of resistance easily distinguishable. Nothing else abnormal was noticed. Iron in various forms had been tried without benefit. A mixture of fluid extract of ergot, fifteen minims, tincture belladonna, five minims, strychnia, one hundredth grain, was given three times daily. At the end of a week she had had only two recurrences of her trouble, and within three weeks she was considered cured. She was then put upon citrate of iron and quinine, with marked benefit. Four months later, all treatment having in the mean time been suspended, the patient, within a week, lost her appetite, looked ill, and suffered twice from the old trouble. A suppository of ergotin, five grains, and cocoa butter, ten grains, was given night and morning, and the iron and quinine mixture renewed. Decided improvement was immediately manifest, and after a fortnight the bowel was under normal control. The suppositories were discontinued after the second week, and the tonic after a month. There has never been a return of the difficulty.

ASCITES IN CHILDHOOD.[1]

Dr. Seiler gives as his opinion that simple ascites in childhood, when tuberculosis is excluded, always depends on hepatitis syphilitica diffusa or circumscripta gummosa, even in cases where all other signs of a syphilitic disease are wanting. The cases so far as he knows are all to be placed in the category of hereditary syphilis, and are curable by mercury and iodine. The only other possibility which he acknowledges is that there may occur in childhood a curable idiopathic hypertrophic liver cirrhosis. Dr. Seiler is not able to bring anatomical proof of the correctness of his statement, but reports observations which may serve to illustrate it, in that the ascites disappeared under antisyphilitic treatment. The ascites may be due to local disease of the peritonæum or to circulatory disturbances in the portal system. Ascites as a consequence of chronic primary peritonitis is not a clinical certainty, though Henoch has claimed its existence in one case of traumatic origin. The existence of cirrhosis of the liver in childhood is also not proved, and its occurrence is doubtful; cases classed under this head all appear to depend upon syphilis, and, moreover, the diffuse syphilitic hepatitis and the hypertrophic stage of cirrhosis cannot with certainty be distinguished.

SYPHILITIC HEPATITIS IN CHILDREN.[2]

Dr. Hugo Engel reports the case of a girl ten years of age, who, from the symptoms before and their disappearance after syphilitic treatment, he supposed to be a case of retarded hereditary syphilis represented by a syphilitic hepatitis. He also speaks of another case occurring in a girl seven years of age. Both cases recovered entirely; the ascites, enlarged liver and spleen, and dyspeptic symptoms disappeared, and have not returned. Dr. Engel then discusses the pathology of the disease, and speaks of the difficulty of diagnosis in childhood, arising often from there being no history of syphilis which can be ascertained. Dr. Seiler considers the essential points in the diagnosis of syphilitic hepatitis in children: (1.) A history of the case like this, the child having been for some time occasionally unwell without any special known ailment. (2.) The peculiar color of the skin and the somewhat cachectic appearance of a child who otherwise seems to be in good health. (3.) Ascites with the following peculiarities: (*a.*) Its gradual development and the absence of any of the usual causes; no tubercular peritonitis, no cancer, etc. (*b.*) Absence of pain, almost no tenderness, and no hæmorrhage from either nose, stomach, or intestines. (*c.*) After paracentesis liver very much enlarged, smooth margin, and hypertrophied spleen. (4.) The accompanying dyspepsia, but entire absence of any other symptoms. (5.) The success of the antisyphilitic treatment, which, while it may do good in other cases, would never be so rapidly successful, and not go hand in hand with such apparent improvement of the general health of the child. (6.) The peculiar fact that all cases of diffused hepatitis due to hereditary syphilis so far reported happened in girls.

CEREBRAL SYMPTOMS PRODUCED BY ASCARIDES.[3]

Dr. D. Juan Samada reports[4] a case in which symptoms of acute meningitis were produced by the presence of a large number of ascarides lumbricoides. The patient was a boy about eight years old. His attack began with severe headache, attributed to a fall sustained a few days before. This was followed by photophobia, conjunctival injection, and later by profound coma. Constipation was present, and as a saline purgative did not produce an evacuation calomel and aloes were administered. This produced several evacuations, each containing about thirty ascarides. The head symptoms ceased from the moment the bowels were purged, as if by magic.

PERFORATION OF INTESTINE BY ASCARIDES.[5]

Dr. E. Monens reports the case of a girl thirteen and a half years old, intellectually badly developed, and an onanist, who suddenly sickened with symptoms of vomiting and pain in the abdomen, of such violent nature that she became mad and could not be examined. On the next day there was well-marked, diffuse peritonitis, and six days later she died. At the autopsy, besides a diffuse purulent peritonitis, there were found (still living) in the descending portion of the duodenum three large round worms. On the inner side of the intestine was a perforation six mm. long, the bloodless edges of which lay quite close upon each other. In the duodenum were four more worms. The deceased Professor Perlo declared this case to be one of ascarido-phagic perforation, the existence of which he had previously doubted, though Leuckart in his time acknowledged without hesitation the possibility of such intestinal perforation, and veterinary surgeons have made observations of cases which cannot be disputed.

URETHRAL CALCULUS.[6]

Dr. S. Trorzki reports the case of a urethral stone in a boy one month old. The infant was otherwise healthy, but from the eighth day on the mother noticed that he cried when attempting to pass water, and seemed to get along easier when the pelvis was

elevated. At the end of the first month the difficulty increased, and raising the pelvis did no good. The author saw the infant after twenty-four hours' retention of urine, and found a swelling about the middle of the penis, evidently caused by a urethral calculus. By a milking movement it was pushed forward to the meatus; this was laid open and the stone removed. It was hard, yellowish brown, and weighed 0.25; it was eight mm. long and five broad, and gave the murexid reaction. After its removal the boy passed a glass of acid urine containing crystals of uric acid and urates. Judging from the size of the stone it must have been of intrauterine development. An uncle of the infant died of urolithiasis.

LEPTO-MENINGITIS INFANTUM.[1]

Dr. William Fraser reports the case of an infant fourteen months old, unusually well developed, and perfectly well until June, when he began to be irritable and to lose in weight; the bowels were regular, and when he was first seen in July his pulse 99.5° F., and he had no other symptoms beyond what would be expected from the condition of the gums, which were hot and tender. Three days later a convulsion occurred, and two days later hemiplegia of the left side; the pulse was then found to be 130, small and irregular, the temperature 101.5° F.; sensation was perfect on both sides. At midnight he began to be convulsed, and this continued with irregular intervals until the next morning; the entire voluntary muscular system was then found to be in a state of tonic spasm, the limbs were rigid, the thorax arched, and the head retracted on the trunk. This tonic spasm was interrupted at intervals of half an hour by a series of clonic seizures involving chiefly the extremities. While these continued the thumbs and fingers were bent into the palm, and the fore-arms flexed and extended upon the arms by short, rapid, rhythmical movements.

The inferior extremities were similarly affected, though in a minor degree; the movements extended also to the face, giving rise to hideous contortions. The respiration was irregular, but there was no lividity. Pulse 140; temperature 102° F. Three days later, the previous symptoms having in the mean time continued, there was a diminution in the convulsions, but consciousness was almost entirely abolished, and there was an increasing tendency to coma; the pupils were contracted, there was entire inability to swallow, and the infant gradually sank, and died at six P. M. The post mortem was made twenty-four hours after death. On opening the skull and reflecting the dura mater, the convolutions appeared flattened, as if they had been slightly compressed. The veins of the cerebral cortex were much engorged. The outer surface of the visceral layer of the arachnoid was smooth and dry, but at a spot the size of a half crown, situated about the middle of the ascending frontal and parietal convolutions of the left hemisphere, the pia mater was covered by a thin yellowish layer of lymph. During the removal of the brain several ounces of clear serous fluid escaped from the lateral ventricles. On section of the hemispheres the centrum semiovale did not present any unusual number of vascular points on either side, but the substance of both hemispheres, and especially that of the left, was very soft.

The optic thalamus and lenticular nucleus of the left hemisphere were so much softened as to be almost diffluent. The ependyma of the lateral ventricles was soft and uneven, and it appeared in parts to be covered by a layer of lymph, but the surrounding textures were so much softened that it was doubtful whether the layer consisted of lymph or of the smooth and softened ependyma. At the base of the brain a layer of lymph about one eighth of an inch in thickness was found in the interpeduncular space underneath the visceral layer of the arachnoid. The inner surface of the dura mater at the base of the skull was perfectly smooth and without a trace of opacity.

GASTRIC ULCER.[2]

Dr. Adof Wertheimber reports the case of an anæmic girl ten years of age, who, after for several weeks suffering from dyspeptic symptoms, was suddenly seized with pain in the epigastrium; the pain soon subsided, but a few hours later returned, and was accompanied by nausea and vomiting of about a coffee spoonful of bright red blood. Blood was also found mixed with the next discharge of fæces. Nothing abnormal could be found in the lungs. The hæmatemesis occurred every day, and sometimes oftener, for a week; the child then presenting the features of a typical case of gastric ulcer was placed on milk diet, and soon recovered entirely. The case is interesting on account of the age of the child. Widerhofer and Kundrat have, as the result of their investigations in this direction, come to the conclusion that the round ulcus ventriculi is very rare during the first ten years of life, while, on the contrary, hæmorrhagic infiltration of the gastric mucous membrane and the erosions which precede gastric ulcer are frequently found. Budd[3] and others have observed that the perforating gastric ulcer seldom occurs before the sixteenth year, one case only having been found, a girl fourteen and a half years of age. Rokitansky never met with it under the age of fourteen. Brinton speaks of two cases between the ages of one and ten years.

WORCESTER CITY HOSPITAL.

SERVICE OF RUFUS WOODWARD, M. D.

REPORTED BY L. F. WOODWARD, M. D.

COMPOUND DISLOCATION OF THE HIP.

JOHN S., aged twelve, while playing on the railroad track, November 11th, was caught under the wheels of a moving freight car, and rolled over and over, the wheels not passing over his body, except that a toe on one foot was crushed.

He was moved immediately to the hospital, and the visiting surgeon, Dr. Rufus Woodward, sent for. His injuries were found to consist of simple fractures of the right humerus and the left femur, a crush of the great toe on the right foot, and a compound dislocation of the head of the right femur.

The compound opening was situated on the inner side of the thigh, about two and one half inches below the angle of the pubes, and was a longitudinal slit about two inches in length. The leg was abducted,

making an angle of nearly forty-five degrees with the body, and the foot was everted. The head of the bone, together with the great trochanter, projected completely through the opening for about four inches, and lay across the scrotum. Its point of exit was just anterior to the adductor longus muscle. The ligamentum teres was torn out from the head of the femur, leaving a depression in the cartilage. The muscular attachments were torn away from the great trochanter and upper part of the shaft, leaving the projecting portion entirely denuded. There was no fracture of either the femur or pelvis detected, and the great vessels were not injured. The hæmorrhage was slight, and the soft parts, about the thigh and hip, not extensively lacerated.

The patient was nearly pulseless when he arrived at the hospital, and no attempt at reduction was made before death. He lived about five hours, and died from shock. After death a prolonged attempt was made by manipulation, without success, the muscular attachments falling over the acetabulum, and so preventing the replacement.

On looking up the subject of compound dislocation of the hip I find that most of the authors either make no mention of it or else say that it cannot occur. Hamilton, in his work on Fractures and Dislocations, writes as follows: "Sir Astley Cooper says he had never seen a compound dislocation of the hip, and believed that it was rarely so dislocated. Mr. Bransby Cooper has, however, reported in detail a very interesting case of this accident, communicated to him by Dr. Walker, of Charlestown, Mass., in which reduction was accomplished by Dr. William Ingalls, by manipulation alone, on the second day. The patient lived three weeks."[1]

As far as I am able to learn the above case is the only one heretofore reported.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY.

OBSTETRIC AND GYNÆCOLOGICAL SECTION.

J. B. SWIFT, M. D., SECRETARY.

NOVEMBER 11, 1882. DR. E. M. BUCKINGHAM read a paper entitled —

ERGOT AND RUPTURED UTERUS.[2]

At the conclusion of the paper Dr. Buckingham said the amount of shock is very variable. Robert Lee reports a case in which the child escaped through the tear into the peritonæum, and was delivered by the feet. Ten hours after delivery there were no symptoms of rupture; pulse 70; vomiting and tenderness absent until peritonitis began on the third day. Hardy and McClintock report that a woman with rupture was driven to the hospital, and, leaning on two other women, walked from the carriage up two flights of stairs to the ward.

DR. CHENERY asked the proportion of cases of ruptured uterus which proved fatal.

DR. BUCKINGHAM could not give the statistics, but thought it a very fatal accident.

DR. SHERMAN asked if the diagnosis of rupture could have been made when the patient was first seen, and if so what would have been the treatment.

DR. BUCKINGHAM said he did not see how the diagnosis could have been made, the woman apparently being in good condition, and no history of collapse having been obtained, but it merely being known that after having had these severe pains suddenly there was an entire cessation of all pain. But should he have another case with such symptoms, after ergot having been given, he should certainly suspect a rupture. Collapse does not always exist. The treatment would be to empty the uterus as soon as possible.

DR. COBB asked if the child was dead when the patient was first seen.

DR. BUCKINGHAM replied that he could not say positively, although he thought so. He could not hear the fœtal heart. When he turned the child, it was certainly dead.

DR. C. P. STRONG asked if the uterus contracted after the child was delivered.

DR. BUCKINGHAM replied that it did not.

DR. MCCOLLOM said that in the cases of ruptured uterus which had not proved fatal contraction had taken place, and this was the reason for the cure, as the contraction prevented hæmorrhage.

DR. STRONG thought it was curious that in this case, if the uterus did not contract, that there was no hæmorrhage into the peritoneal cavity.

DR. HARLOW spoke of a case he had seen. The woman had been in labor some time under the care of a midwife. He could not say certainly that ergot had been given, but thought it probable. Similar symptoms to those of the case reported came on, and he was sent for. On examination found that the uterus was ruptured, but the woman being in a state of collapse, and evidently dying, no attempt at delivery was made. The autopsy showed the uterus lacerated from the fundus entirely through the os. There was not much hæmorrhage, but the patient was collapsed when first seen.

DR. CHENERY spoke of a case which he had seen where the attending physician, in order to hasten delivery, had given a large dose of ergot, which produced most violent cramps, putting the woman into such agony that a large dose of morphia was required to relieve her, and which probably was the best thing that could have been given. The pains having ceased, and showing no signs of returning, he had been sent for to apply forceps. On examination he found an entire absence of pains, the os only dilated to the size of a silver quarter. It was a long time before the pains returned, and then they were too feeble to accomplish delivery, so that it was effected almost entirely by the voluntary muscles and pressure from above.

DR. LYMAN said the practical point to be brought out was as to the advisability of administering ergot during labor, and called for the views and practice of the members.

DR. HARLOW said authorities differ as to its use, some saying that the contractions caused thereby could not rupture the uterus. He had used it in some tedious cases in the beginning of his practice, but now does not do so, using the forceps instead where interference or aid is needed. Thinks it might be of service if it overcame the obstacle, but if it failed to do this it would kill the child.

DR. MCCOLLOM said he never gave ergot until after

[1] Vide Dislocations and Fractures of the Joints, by Sir Astley Cooper. Edited by Bransby Cooper. Edition of 1844. Page 80

[2] See page 125 of this number of the JOURNAL.

the birth of the placenta. Thinks it causes spasm of the uterus, and so prevents the very thing desired. Given after the birth of the placenta it prevents after-pains by preventing hæmorrhage, which is the cause of the pains. Has seen a very extensive laceration of the perinæum caused by ergot given by a medical student, the child, placenta, and membranes being forced out all together by one pain.

Dr. Buckingham said the uterus can be ruptured by the natural contractions where there is obstruction, so if ergot intensifies these contractions, would think that ergot would cause rupture all the more. Murphy reports ten cases without obstruction.

Dr. Lyman said the weight of testimony was all against the use of ergot until after the placenta had been delivered. Now that there were better ways of controlling labor, ergot had fallen into disuse. A number of years ago McClintock and Hardy, of Dublin, had shown that ergot endangered the life of the child, and no one since then had successfully contradicted this. Death was supposed to be caused in two ways: (1) by a direct poisonous influence, and (2) by compression. Formerly it was his custom to give ergot, the cervix being dilated or dilatable, in order to hasten the delivery, but now he was afraid to use it before delivery of the placenta. He has certainly had cases where the placenta remained a long time owing to the use of ergot. He agrees with Dr. McCollom in thinking that ergot given after the birth of the placenta diminishes the after-pains. It is his routine custom in all cases, primiparæ as well as multiparæ, to give a drachm of Squibb's fluid extract of ergot after the placenta is born, seeing first that the uterus is emptied of clots. He gives it for two reasons: (1) to prevent after-pains, and (2) as a prophylactic against possible post-partum hæmorrhage.

Dr. W. A. Dunn said he had had considerable experience in the use of ergot, having given it in about one hundred cases out of six hundred, when the os was well dilated, in multiparæ, and the head was resting in the inferior strait. He thought it caused the death of the child by causing the uterus to contract on the placenta so as to cut off the circulation. Has seen most intense cyanosis in the child follow its use. Now he seldom gives it until after the birth of the placenta. In a very rapid delivery where he fears hæmorrhage he gives it before the placenta is born. Never had a placenta retained more than twenty minutes. He thinks that the teaching of ten years ago was not so pronounced against the use of ergot as it is to-day. He was under the impression that formerly the older physicians were rather more disposed to hasten the labor by a dose of ergot. At the present time the student is most emphatically warned not to give ergot until the uterus is empty.

Dr. McDonough asked if it would be possible by a microscopical examination to tell whether or not the uterus had been ruptured by external violence, and spoke of a medico-legal case in which it had been claimed that this could be done.

Dr. Cobb, referring to retained placenta, said he had seen the placenta retained from half to three quarters of an hour, although compression had been employed all the time.

Dr. Swift spoke of the custom in Paris, at the Clinique d'Accouchement, of leaving the placenta entirely alone. He had seen one hundred cases there where nothing was done to help its expulsion, not even following down the uterus during the labor. When the child was born the cord was cut, and the child removed to be weighed, measured, etc. During this time the mother was left alone, and by the time they had finished with the child the placenta was found in the bed. Ergot was never given either before or after the delivery unless there was too much flowing.

Dr Lyman said, speaking of after-pains, that he had seen them caused by a clot in the vagina. He had a patient who had a very long perinæum. She had never had a child, and the fourchette came well forward, making a pouch in the vagina. She has a small fibroid, and at her menstrual periods, two or three days before the flow begins, there is an oozing, and a clot the size of a pigeon's egg forms. Until this comes away she has pains resembling after-pains. Has seen the placenta forced out of the vagina by the contractions, and considers these caused by the reflex action due to the irritation in the vagina.

Dr. McCollom has known clots in the vagina to cause after-pains, which were relieved by removing the clots.

Dr. Sherman asked if any other preparation of ergot besides the fluid extract had been used by any of the members.

Dr. Harlow said that formerly he used the powder, fifteen to twenty grains, in hot water, but it frequently caused vomiting. Then he used Squibb's fluid extract, and now uses ergotine pills, they being the most convenient form to carry.

Dr. J. N. Hall asked if it was common for the placenta to be retained in abortions at the third or fourth month, and in such cases what was the treatment.

Dr. Cobb said he had seen such a case where the placenta remained eight days, and then came away of itself.

Dr. Lyman said it was very common to have the placenta remain, and that was the great trouble in these cases. It was quite common practice, but an erroneous one, to give ergot in abortion, because it causes the uterus to contract about the placenta, and so prevents its coming away. He cited several cases where it had been given, and great trouble was experienced in removing the placenta afterwards. The thing to do was to clean out the uterus, and the hæmorrhage would stop.

Dr. Lyman thinks that ergot does not do any good in metrorrhagia. In menorrhagia it more often increases the trouble, as it also does in hæmorrhage from fibroids. The latter is much more often relieved by dilatation of the cervix.

Dr. Chenery spoke of a case where he found a fœtus, with the membranes and placenta, in the chamber vessel, but hæmorrhage continuing he examined the patient, and found another fœtus in the membranes hanging through the os into the vagina. In trying to draw this out it slipped back into the uterus out of his reach, so, thinking to force it out, he gave a dose of ergot, but instead of the fœtus coming the hæmorrhage stopped, and the woman went to full term.

Dr. Chenery asked what was the relation between early escape of the liquor amnii and a still-born infant. He had had a case where the liquor amnii escaped three or four days before delivery, so that the labor was what is known as a dry one. The child was still-born, and the placenta was only half the normal size. Did the absence of the liquor amnii allow the uterus

to contract so as to compress the placenta and shut off the circulation? If so, should anything be done in these cases?

DR. HARLOW said this same subject had been discussed some years ago, and the conclusion arrived at then was that no interference was necessary. A case had been reported at that time where the membranes ruptured a number of days before delivery, but the child was born alive.

DR. STRONG thought that the fœtal heart would be an indication as to interference.

DR. DUNN spoke of a case of imperforate anus with absence of the rectum, which he had had, where colotomy had been performed, and the child lived for fifteen days. A day or two after this case he had one of imperforate anus, the obstruction being only a slight septum, which was easily divided.

DR. HARLOW said he had had two cases of imperforate anus; both children died after being relieved for a time by an operation.

DR. R. B. DIXON presented a new perforator, a description of which was published in this JOURNAL, vol. cvii. p. 544.

NATIONAL ASSOCIATION FOR THE PROTECTION OF THE INSANE.

AN important meeting of the National Association for the Protection of the Insane and the Prevention of Insanity was held in Philadelphia January 25th and 26th. Three sessions were held at which the attendance was highly satisfactory as regards the size and character of the audience assembled, and the number and variety of papers presented, and the interest shown in the discussions. The Association held its meetings at the College of Physicians. Prof. S. D. Gross, on the first day, entertained the members at dinner.

DR. JOSEPH PARRISH, of Burlington, N. J., presided at the meeting.

PROFESSOR GROSS delivered an address of welcome, in which he called attention to some prevailing faults in the present methods of treatment of the insane, the need of better classification of cases under treatment, and the want of more intelligent study of the causes of insanity, especially in individual cases, in order to obtain a more rational treatment.

A paper on the

FUNCTIONS OF A MEDICAL STAFF OF AN INSANE HOSPITAL

was read by DR. TRAILL GREEN, of Easton, Pa., in which the author dwelt upon the insufficient provision for the increasing numbers of the insane, and insisted that a larger medical staff is required to properly provide for the insane than is usually found in the public institutions for their treatment.

On motion of PROFESSOR GROSS a resolution was passed recommending "the addition of a gynæcologist to the medical staff of every hospital for the insane, female practitioners preferred."

DR. CHARLES K. MILLS, of Philadelphia, read a paper on

THE DUTY OF MEDICAL COLLEGES AND THE GENERAL PRACTITIONER TOWARDS MENTAL AND NERVOUS DISEASES.

While increasing attention is paid to nervous diseases, and a better knowledge of neuro-pathology is provided by our medical schools, nowhere is there a thorough system of clinical teaching on insanity. He advocated larger asylums, and clinical lectures on this subject, attendance being made compulsory prior to graduation. The duty of medical colleges towards mental diseases is embodied in the single statement that the colleges are bound to give instruction equal in quantity and quality to that which is afforded in any well recognized special department of medicine.

On motion the secretary was directed to memorialize the medical schools throughout this country upon the necessity of establishing lectureships upon mental disease.

DR. JOSEPH PARRISH read a communication entitled

HOW TO PROTECT THE INSANE.

Speaking of the importance of the subject he said: If there is one subject before the people of this generation about which there is much felt and feared, and about which there is but little known and understood, that subject is insanity. We are told by eminent alienists and statisticians that the disorder is on the increase. Asylum reports and eminent authors in this sphere of professional service inform us that, with the increase of insanity, which is said to be out of all reasonable proportion to the increase of population, there is a striking decrease in the rate of cures. Insanity is permitted to hold the preëminence in defying all means that have been so far tried to render it amenable to remedies. The essayist referred to county poor-houses, but a few hours distant, where scenes might be witnessed of insane fellow-beings, without the ordinary comforts and attentions that are bestowed upon the meanest of men whose reason has not been dethroned.

Referring to the assumed incurability of the chronic insane, and the popular demand for a false economy in the conduct of public and especially pauper institutions, he said: Have we any right to say that chronic insanity is incurable? Have we any definite line by which we can differentiate between the chronic and acute? He believed the teaching of asylum officials in this regard might be reconsidered with advantage. We want no further necessity for writs of habeas corpus in order that a citizen may find his way from a hospital or asylum to his home. We want no more harsh mechanical restraints applied to the bodies of our fellow-men who are deprived of their reason. We want no more such false economy in the administration of county poor-houses as will confine a patient in a disgusting cell from one year to another rather than be at the cost of an attendant to walk or ride with him in the open air, or teach him some occupation. We want in every State of this Union an intelligent and faithful lunacy commission that shall have power under the seal of the Commonwealth to open every door behind which a lunatic sits, examine every case, hear every complaint, and act in harmony with medical superintendents and officers of such asylums so far as it may be possible to secure the largest freedom compatible with safety, and the highest intelligence in their management of the insane. We want intermediate homes, where nervous and disordered persons who are drifting toward insanity may place themselves.

The report of the secretary, MISS CHEVAILLIER, was then presented and referred to the Board of Council of the Association.

DR. DANA, of New York, offered a series of resolu-

tions relative to the death of Dr. George M. Beard, which were adopted by the Association.

In the evening REV. R. HEBER NEWTON, of New York, read a paper on the Obligations of the Sane towards the Insane, and DR. H. MARION SIMS presented an essay on the Prevention of Insanity in Certain Cases of Nervous and Hysterical Women. This class of cases are commonly curable, and the speaker urged moral treatment, and discouraged commitment to asylums without careful examination and study of the cases.

In the discussion of these papers it was distinctly stated that there is no desire on the part of the Association to antagonize superintendents of insane hospitals, and individual expressions of confidence in the officers of such institutions were made, but dissatisfaction was freely expressed with the present easy system of commitments to hospitals, and the want of proper supervision by the State authorities of these institutions

MR. CLARK BELL, President of the New York Medico-Legal Society, then read a paper on

THE LEGAL RIGHTS OF THE INSANE, AND THEIR ENFORCEMENT.

He referred to the army of one hundred thousand souls in the United States who were most defenseless, and in whose behalf he was appointed to speak. The act passed in England in August, 1845, may well be described as the Magna Charta of the liberties of the insane.

Mr. Bell then proceeded to give a statement of the legislation from time to time adopted in England in favor of the insane. He said there was no proper provision for the examination of the patients in the public and private asylums of New York. There is needed in that State a lunacy commission almost as large as that of England to do the work well. A superintendent of an asylum, under the laws of most of the States, is an absolute monarch. There never was a time when courts and juries engaged in the investigation of cases of alleged insanity should be more careful than at present.

A most important step is to secure as early as possible the appointment of a board of commissioners in lunacy, with compulsory visitation and examination of patients at least twice a year. It is also important that a constant supervision should be kept on the superintendents. It should be the duty of the State to provide separate receptacles for the incurable insane. Seclusion should be abolished as a punishment, and there should be, in fact, no punishment. The insane should be provided with employment and plenty of exercise in the open air.

On motion of DR. DANA, of New York, a committee of three was appointed to prepare and present a report on the proper law regarding the care of the insane; a committee of three on statistics to keep account of facts regarding the increase of insanity and the condition of the insane in the United States, to report at next meeting.

OFFICERS.

The following officers were elected to serve the ensuing year: President, Dr. Joseph Parrish, of Burlington, N. J.; Vice-Presidents, J. S. Jewell, M. D., Chicago, C. C. Yemans, M. D., Detroit, E. C. Seguin, M. D., New York, Mary Putnam Jacobi, M. D., New York, C. L. Dana, M. D., New York, and several others; Secretary and Treasurer, Miss A. A. Chevallier, of Boston; Executive Committee, the President, the Secretary, Dr. W. B. Atkinson, and Dr. C. K. Mills, of Philadelphia, Clark Bell, Esq., of New York.

SECOND DAY'S PROCEEDINGS.

The second day closed the proceedings with the morning session, at which several papers on the relationship of insanity to inebriety were read. A contribution, entitled, The Prevention of Insanity by the Rational Treatment of Inebriety, presented by Dr. T. D. Crothers, of Connecticut; and one on The Connection between Alcoholism and Insanity, by Dr. A. Baer, of Berlin, read by Dr. Carl Seiler, lead to a warm discussion upon intemperance and its causes. Dr. J. Milner Fothergill, of London, sent a contribution, which was read, entitled, Do Perversions of Assimilation Play any Part in the Production of Insanity, in which a case was quoted where gout seemed to favor the development of chronic mania. Without asserting that insanity may depend upon the digestive organs, it was believed that mal-products of digestion may aid in the action of other causes of insanity. A paper on the Systematic Education of the Insane as a Means of Cure, by Dr. James Lalor, superintendent of the district asylum, Dublin, was read by Dr. Ulrich, of Chester, in which some forms of congenial occupation and more free association of patients were recommended, by which a great reduction in restraint can be obtained. Some of the Conditions of Life which Influence the Production of Insanity were considered in a paper sent from England by Dr. Charles Mercier, assistant superintendent of the Lunatic Hospital of the city of London. The principal causes assigned being sudden emotion causing mental shock, complexity or arduousness of occupation inducing mental strain; but precariousness of means of livelihood was considered one of the most potent causes.

RESOLUTIONS.

Resolutions were adopted recommending to the careful consideration of physicians and superintendents connected with institutions for the treatment of mental diseases the value of regular and pleasant employment of their patients as a remedial agency.

That the report of the Medico-Legal Society presented by its President be accepted, and that the Association print an abstract of this valuable report in the journal of the Association.

That the Association recommend to the legislatures of the several States the adoption of a similar law to the one passed in Pennsylvania imposing penalties for false certificates of insanity.

— An affair unfortunate for the advocates of "co-education" in medicine has recently occurred at Kingston, Canada, which seems to have been precipitated by the women themselves. It seems that there have been mixed medical classes, and recently the ladies took offense at a remark made by the professor of physiology, and left the theatre in a body. Thereupon the male students petitioned the Faculty to dismiss the ladies, and even went so far as to threaten to leave the school themselves if their request were not complied with. A compromise was agreed upon: the ladies now attending classes will be permitted to finish their course, but no more will be allowed to enter, and for the future the medical school will be for men only.

Recent Literature.

Legal Medicine. By CHARLES MEYMOTT TIDY, M. B., F. C. S., Professor of Chemistry and of Forensic Medicine and Public Health at the London Hospital, etc. Part I. Pages xxx., 633. American edition. Henry C. Lea's Sons. 1883.

The same. New York: William Wood & Co. "Library of Standard Medical Authors." 2 vols. 1882.

Taylor defines legal medicine as "the science which teaches the application of every branch of medical knowledge to the purposes of the law." The work, of which the first volume only is before us, is a good illustration of this far-reaching definition; in comprehensive scope, in variety of topics, in wealth of learning, it seems admirably fitted, if carried on successfully to the end, to fulfill its author's design to make it "a complete treatise on legal medicine." We have had nothing approaching it in plan and in elaboration since the well-known and voluminous work of Wharton and Stillé was issued, ten years ago, in its last edition. He whose inclinations or necessities lead him to assume the functions of a medical jurist, (and the necessities occur too often without the inclinations) wants a book, encyclopædic in character, in which he may be reasonably sure of finding medico-legal topics discussed with judicial fairness, with sufficient completeness, and with due attention to the most recent advances in medical science. Mr. Tidy's treatise bids fair to meet this need satisfactorily. In two particulars it is especially pleasing. One of these is the freedom of the text from the tedious discussion of purely legal points, the author's consistent purpose being to aid physicians in practicing legal medicine, rather than to aid lawyers in surmounting legal difficulties; in this regard the volume is in refreshing contrast with some of the standard text-books. And another excellent feature is the admirable manner in which illustrative cases are introduced, each chapter having an appendix of citations, carefully compiled from original sources. To these cases reference is made parenthetically in the text, and, as in Casper's great work, the author's observations on the subject under discussion do not suffer interruption, while repetitions growing out of the applicability of the same illustration to various themes are avoided. The fact that these very numerous illustrative cases are drawn from many sources and are not limited, as in Casper's hand-book, to the author's own experience, and the additional fact that they are brought down to a very recent date, give them, for purposes of reference, a very obvious value.

Every one of the twelve chapters of this first volume presents attractive material for critical analysis; but only the briefest outline of the author's treatment of his subject can be given.

The introductory section, devoted to a consideration of the general characters of forensic medicine, of the occasions calling for its practice, and of the behavior of the medical witness both in preparing his testimony and in presenting it in court, is the most readable of all in the book. The author here uses the familiar style of a teacher addressing his class, and whatever may be lost thereby in the way of conciseness is more than counterbalanced in attractiveness. The physician who strives to shape his conduct according to the rules and principles here enunciated will find his experience in the witness-box far more pleasant to recall than is commonly the case.

The second chapter is devoted to the signs of death, and to the phenomena and appearances resulting from the march of post-mortem changes in the human body. The topic of cadaveric rigidity is treated at considerable length. The author accepts the theory of Kühne, that rigor mortis is due to a coagulation of myosin in consequence of an accumulation of acid products in the muscles. That remarkable condition of the recently dead body called by some writers "instantaneous rigor," or "cadaveric spasm," is held by Tidy to be physiologically identical with rigor mortis, and not to be distinguished therefrom save in the element of time at which the rigidity occurs; he admits, however, the great assistance afforded by it in determining questions of real or simulated suicide.

The subject of personal identity in the living and in the dead is discussed in the third chapter, with special reference to questions of age, sex, stature, race, cicatrices, tattoo-marks, and other related topics. In connection with the measurement of the skeleton and its component parts, the tables of Orfila, now discredited by many authorities, are quoted, "chiefly for the purpose of showing that the medical jurist must not be too dogmatic on the relative length of bones." When describing the microscopic examination of human hairs in homicide cases, the author gives the following judicious counsel: "The observations, to be valuable, should be numerous. Correspondence, the result of a single observation, should not be deemed sufficient to prove identity. . . . In giving evidence, it will be safer to say that two hairs are similar than that they are identical." And in the same chapter, under the head of blood-stains, he remarks: "It would, in our judgment, be exceedingly unwise to hazard an opinion as to the source of a given specimen of blood, from the microscopic measurement of the disks." What would Mr. Tidy say to some of the expert testimony in this country in recent years, in the matter of human hairs and blood-stains in capital cases?

The fourth and fifth chapters give a classification of the various forms of sudden death, and a good description of the details of a medico-legal autopsy.

Under the topic "Sex," in the next chapter, hermaphrodism receives full attention. The author declares that the only reliable test of sex, in doubtful cases, is the character of the genital gland, the individual being female if the gland proves to be an ovary, and male if a testicle is demonstrated. It is plain that this test is of rather limited application during life, and that reliance must be had mainly on such functional phenomena as are observable after the age of puberty is reached — on menstruation, if the sex be female, and on seminal activity if the sex be male. The author properly defines true hermaphrodism as "the co-existence in a single individual of completely developed ovaries and testicles, or of one, at least, of each gland;" and he adds, "It is scarcely open to question that, in the strict sense, a true hermaphrodite has never existed, more especially if we regard as essential that the individual shall perform the functions of either sex indifferently and effect self-impregnation." To this statement, we believe that most medico-legal writers of the present day will assent.

The chapter on life insurance and survivorship requires no special comment. It is chiefly of interest to English readers.

The symptoms and post-mortem appearances resulting from exposure to extreme cold and heat (including insolation), are fully described; so, too, are the medico-legal relations of burns and scalds. In connection with the latter subject, the author formulates some conclusions from his own experiments undertaken to define the means of distinguishing burns inflicted during life from those made on the dead body. The most important statement is this: "Given a blister containing a little thin, non-albuminous serum, without any red line surrounding the blister and without any injected condition of the cutis vera or subcutaneous tissues, the evidence is strong that the burn was inflicted after death."

Much of the chapter on combustibles and explosives seems rather out of place in a medico-legal treatise, a single topic only, that of the spontaneous combustion of the human body, being of immediate interest; and on this topic the author is brief, his principal proposition being that "there is no authentic case of true 'spontaneous' combustion of the human body on record," the alleged cases being instances of death by fire under peculiar circumstances.

The closing chapter treats of starvation, with an incidental study of food in its physiological and hygienic relations. The post mortem appearances in death by starvation are fully described with full reference to recorded cases. The author pays his respects to Dr. Tanner in a way not altogether complimentary to that gentleman.

This brief sketch of Mr. Tidy's work gives necessarily a very imperfect notion of its scope and its fullness of detail. The author has not contented himself with a repetition of time-honored medico-legal ideas in new phrases, but has been at once original and conservative, accepting that which experience has proved to be trustworthy, without giving the weight of authority to the obsolete on the one hand, or to the untried novelties on the other. The whole tone of the volume, indeed, has its key-note in the following sentence, taken from the preface: "For the medical jurist, whose object should be the interests of justice, to hesitate where science is positive, is as unjustifiable as for him to speak without reserve on those details of our science, where the limits of exact scientific knowledge are undefined. There is a scientific certainty which only a coward treats as uncertainty, and there is an uncertainty which only the boldness of ignorance ignores." If the author's plan is carried forward in the remaining volumes of the series with as much success as is auspiciously displayed in this initial work, he will place under great obligation all who are interested in legal medicine, and will illustrate a new departure in this field of medical science.

We must not omit to mention the fine manner in which English type and engraving skill have aided in introducing the author to his readers.

Address Delivered before the American Academy of Dental Science at their Fifteenth Annual Meeting. By FRANK ABBOTT, M. D.

This address is particularly interesting because the writer, although himself a teacher in a dental college, advocates a medical course as an essential in the education of a dentist. Viewing the subject historically, he shows that before the eighteenth century those who practiced upon the teeth were always physicians; but between this time and the establishment of the dental colleges the care of the teeth passed mainly into the hands of barbers and jewelers, who, although they improved the mechanical details, prevented dentistry from being recognized as a specialty in medicine. He justly states that until dentists again become physicians they cannot expect medical men to consider them upon the same plane as other medical specialists.

In commenting upon the statement of Mr. Eliot, that though a medical education was a desirable thing for the dentist, it required such extraordinary zeal in the student that few would pursue that excellent course, Dr. Abbott remarks that without this extraordinary zeal the student had better not enter the profession.

Briefly, Dr. Abbott's position is this: A three or four years' medical education, followed by a special course of two years or more in a dental college, should be required from dental students. R.

A Practical Treatise of the Diseases of the Uterus, Ovaries, and Fallopian Tubes. By A. COURTY. Translated from the Third Edition by AGNES M'LAREN, M. D., with a Preface by J. MATTHEWS DUNCAN, M. D. Philadelphia: P. Blakiston, Son & Co. 1883.

This work is a very welcome addition to our gynæcological literature, welcome both for its own inherent value and also as an exponent of the practice of what may be called the French school. While the rapid interchange of knowledge makes the medical world virtually one large school, yet different countries have nevertheless their own peculiar traditions and methods of practice.

Of the leading schools of medical thought it is safe to say that the American medical man is, as a rule, least acquainted with the French. This follows directly from the prominent place Germany holds in the scientific world as the source of the most profound and extensive research, and the consequent attraction it holds out to students.

But France, the country which first gave the impulse to modern gynæcological study, has by no means degenerated, and it is therefore with great pleasure that we find a representative book of this character placed within the reach of American physicians. The author, Dr. Courty, of Montpellier, is one of the most distinguished gynæcologists of France, and this book is the result of his large experience and ripe learning. The book does not attempt to cover the whole field of diseases of the female genital organs, but confines itself to affections of the uterus, ovaries, and Fallopian tubes. There is more in the original French edition, which has been omitted in the translation.

The contents are divided into two parts, preceded by an introductory chapter. The introduction is an exceedingly full and careful account of the anatomy, physiology, and teratology of the organs of generation, and well merits study. Its principal value consists in the fact that, being written by one who has had to make practical use of his anatomical knowledge of these parts in his surgical work, his descriptions are full of useful hints and suggestions about anatomical relations which we look for in vain in pure anatomies. To cite one instance: the author, after describing the different ligaments as means of suspension of the uterus, on pages 24 to 27 refers to their farther use as

regards the divisions which they establish in the pelvic cavity, and shows in a graphic manner how the broad ligaments, for instance, give the key to the differential diagnosis of hæmatocele, pelvic peritonitis, peri-uterine phlegmons, and various other conditions. The section on development and malformations is also very good.

Part I. treats of uterine diseases in general, and shows more than any part of the book the peculiarly large and comprehensive character of Dr. Courty's knowledge. It is manifestly the result, not of any one-sided study of uterine disease as an entity, or of a disposition to look at disease through the medium of his own specialty, but, on the contrary, there is throughout a recognition of the interdependence of local and general symptoms which should be the true aim of the specialist. He treats of the diagnosis of uterine diseases in general, then the presumptive signs indicating uterine disease, and, lastly, those furnished by direct examination. Then follows a full account of the various methods of treatment, constituting in itself a valuable treatise in minor gynæcology, and Part I. closes with some account of the general characteristics of uterine diseases.

Part II. treats of uterine diseases in detail, chapter 1 of functional disorders, chapter 2 of changes of position, chapter 3 morbid states without neoplasm, chapter 4 organic alterations, and chapter 5 diseases of the uterine appendages, with a short section on sterility.

The general impression which one gets from the perusal of this portion of the book is that the author relies more upon medical than surgical means in the treatment of the majority of the affections considered. Hence those chapters which treat of displacements and inflammatory conditions are the best. In other portions we too often find a series of methods of treatment proposed which at the best can be but palliative, and no mention made of simple radical operations. In some cases this is because the true nature of the lesion is not appreciated. For instance, when speaking of acquired hypertrophy of the neck in chapter 3, he gives a description and illustrates it by a plate which perfectly corresponds with what we know as laceration of the cervix, with eversion and hypertrophy of the lips, a condition for which Emmet's operation is the quickest and surest method of cure.

The chapter on displacements is full, and the author's views about pessaries and their indications are in general very satisfactory. We are pleased to see that he gives its proper significance to anteflexion of the neck, recognizing it as a result of faulty development, and the cause of dysmenorrhœa and sterility. He gives the usual unfavorable prognosis in cases of backward displacement with adhesions, and advocates the dangerous method of treatment by forcible reduction with the sound. He does not refer to the gradual method by packing the vagina, which in a large majority of cases will yield very satisfactory results.

The part of the third chapter which treats of granulations and ulcerations of the cervix lacks clearness. It illustrates in what direction Dr. Courty is wanting. With remarkable powers as a clinical observer which enable him to give graphic and clear descriptions of the appearances and symptoms of the various affections of the uterus and its appendages, he lacks precision in his pathology. The book, as a whole, is less satisfactory in this respect than in any other. For instance, he describes a "folliculitis or true acne of the cervix," which is nothing else than a lacerated cervix with great eversion and numerous retention cysts, the so-called ovula Nabothi. The cut accompanying the description is the most perfect representation of a stellate laceration of the cervix that could be wished for.

The chapter on cancer is good, and the operation for amputation of the cervix well described. We think the author's objections to the operation for removal of the whole organ should be modified in the light of the recent improvements in the methods and results achieved especially by the German surgeons.

It is impossible in the limits of a short review to criticise the book as fully as we would wish. Taken as a whole it is a valuable one, chiefly to the specialist. The student or the general practitioner can find others which would be more concise, and hence more available for reference. The translation seems to be very conscientiously done, and the illustrations are very very numerous and exceedingly well executed.

How we Ought to Live. A Practical Guide, written in plain, intelligible Language, for the Preservation of Health and the Attainment of Longevity; designed to enable All so to Live that they may reach Old Age in Health and Comfort. By JOSEPH F. EDWARDS, A. M., M. D., Author of How a Person threatened or afflicted with Bright's Disease Ought to Live, Dyspepsia, and How to Avoid it, etc. Philadelphia: H. C. Watts & Co. 1882. 636 pages.

The scope and aim of this book are sufficiently indicated by its title-page. In some twenty chapters the author discusses, in a style adapted to the popular mind to which it is addressed, the principles of healthful living. The field which he proposes to himself is a wide one, and includes the hygiene of the domicile as well as of the person. Ventilation and drainage, work, food, exercise, bathing, sleep, dress, are all considered in much detail, and the author adds specific directions as to the proper way to live under various peculiar circumstances, as pregnancy, nursing, consumption, heart disease, infancy, childhood, and old age.

The advice given is eminently sound, and but for the fact that it is not chiefly from lack of instruction that the public so generally transgress the laws of health, we should have greater confidence that this work would do much to promote longevity. The book contains a number of letters from old men, written in answer to inquiries by the author regarding personal habits and hereditary characteristics. We are somewhat amused to find among these a quotation from "a great poet-physician, now over seventy years of age, living in the neighborhood of our lamented Longfellow, . . . having an international reputation as a poet-physician and prose writer, etc.," who, the author, regrets to say, "refuses the use of his name."

Through the deep secrecy thus wrapped about the author's correspondent we almost thought we could penetrate, until we discovered that the latter was included among the *old men*, but now the mystery remains unsolved.

The book is well indexed, which will prove a convenience to the public who will use it.

— A female correspondent of *Harper's Bazar* is gravely assured by the editor, in the column of "answers to queries" of a late number, that it would be entirely proper for her to go into society after the birth of a still-born child.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 8, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number: $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

SUBJECTS FOR MASTER'S DEGREE AT HARVARD, 1655–1791.

A FEW years ago a short paper on this subject was submitted at a meeting of the Massachusetts Historical Society by Mr. Edward J. Young, and was reprinted from the Proceedings of the Society.

As but few of our readers, probably, have seen this reprint, it may not be amiss to reproduce a few of the "questions," especially of those relating to science, to physiology, and medicine, as showing the then important and debatable subjects occupying men's minds. Some of them now seem, as our burning and unsettled questions may probably appear to our successors one hundred years hence, merely quaint and curious; some of them stand as milestones in the development and progress of theory and knowledge during the period referred to; one or two mark to our minds a juster sense of what is for the welfare of her citizens than prevails in Massachusetts at the present day.

These "questions" were discussed at Cambridge on the afternoon of Commencement Day, by candidates for the degree of Master of Arts, three years after their graduation, and were translated from the mediæval and modern Latin in which they were originally expressed, by Mr. Young. Among the candidates appear many names afterwards famous in the history of the country. The earliest programme which has been preserved bears the date of 1655, thirty-five years after the landing of the Pilgrims at Plymouth. In regard to the period, Mr. Young pertinently remarks: —

"Then the opinion was entertained that there really was a philosopher's stone, that it was possible to square the circle, and that the planets exerted an influence on terrestrial objects. Though astrology was on the wane, questions relating to divination were still debated, alchemy had not given place to chemistry, and modern science had not yet been born. Men argued whether the earth moved, and whether it was the centre of the universe. In medicine it was taught that a wound could be cured by dressing the implement that caused it. The Bible, literally interpreted, was the rule of faith in regard to all matters."

The question, Are the Americans Israelites? was answered negatively in 1699, and the question, Were the Aborigines of America descended from Abraham? affirmatively in 1773. This question again attracted considerable discussion, both in England and America, not long since. Was there a rainbow before the deluge? This was negatived in 1759, and affirmed in 1766. Did the reptiles of America originate from those that were preserved by Noah? Affirmed in 1769. Is a comet, which only appears after many years, more a foreboding of divine wrath than a planet which rises daily? Negatived in 1770. Can real gold be made by the art of chemistry? Affirmed in 1771. Is the sun inhabitable? Affirmed in 1772 by Theophilus Parsons, subsequently, from 1806 to 1813, Chief Justice of the Supreme Court of Massachusetts. Does the state of the atmosphere, whether salubrious or otherwise, depend to a great degree on subterranean effluviæ? Affirmed in 1768. Is the rarefaction of the atmosphere of comets, when they are nearest the sun, injurious to the birds which fly in it? Affirmed in 1772.

Among the questions relating to society and the State, one as to whether the advice of Paul to Timothy to "use a little wine" would bring him under the power of the tavern keepers was decided negatively in 1754.

Among the questions relating to physiology and medicine were the following: Is heat essential to fever? Does the liver make blood? Both answered in the negative in 1678. Is cold water the most efficacious of all means for removing fever? Affirmed in 1723. For a long time it was thought that the powder of sympathy of Sir Kenelm Digby would cure a wound by being applied to the weapon or instrument that produced it. The question, Is there a sympathetic powder? was answered affirmatively in 1703, 1708, and 1710; and the question, Is the cure of wounds by sympathetic powder lawful? affirmatively in 1693 and 1708. Is there a magnetic method of curing wounds? Affirmative answer in 1698. Is the inoculation of small-pox into human bodies lawful and safe? Affirmed in 1724, and in 1784. Are the natural capacities of men equal, and do they become different only in consequence of the different organs of their bodies? Negative answer in 1722; affirmative in 1741. Does the construction of the organs of the body make all the difference between an idiot and a wise man? Affirmed in 1773, and in 1786. Ought physicians to pray for the health of the people? Affirmed in 1724. Should the fees of physicians on the Lord's Day be counted as their own? Negatived in 1727. Affirmed in 1769. Do medicinal herbs operate by planetary power? Does the pressure of the atmosphere assist the contraction of the chest in the act of expiration? Both of these were answered negatively in 1728. Is there a duct which leads directly from the stomach to the urinary bladder? Negative answer in 1730, affirmative in 1731. Does the concurrence of the optic axes of both eyes of itself suffice to explain simple vision? Negative answer in 1749. Do all diseases arise from obstruction? Negative answer in 1762, by Joseph Warren, subsequently killed at the Battle of Bunker Hill. Did Adam have an umbilical cord? Answered in the negative in 1765, by Jeremy Belknap, subsequently an influential divine in Boston, and founder of the Historical Society, in 1791. Is an excess of eating and drinking sometimes beneficial to the human body? Affirmed in 1767. One of the

subjects proposed for the Boylston Prize Essay in 1882 was, The therapeutic value of food, administered against or beyond the patient's appetite or inclination. By some practitioners of the present day food is administered quite as heroically as were drugs by those of a previous generation. Is the cessation of breathing and of the pulsation of the arteries a sure sign of death? Negative answer in 1786. Did the art of medicine ever restore the health of a body when the healing power of nature could not renew it? Affirmed in 1788.

We close the extracts from these questions, of which many are now considered definitely settled, by two apparently farther from solution and less satisfactorily answered to-day in Massachusetts than they were one hundred and twenty-five years ago. The question, Should any one practice medicine before he has been approved by some competent persons? was answered in the negative in 1741; and the question, Is the toleration of quacks fatal to the people? in the affirmative in 1768.

To-day, in Massachusetts, quacks are fostered, and the State directly facilitates the conferring of medical degrees and the practice of medicine by any body of men, or any individual, however knavish or however ignorant. At the same time otherwise intelligent people are found who heedlessly stamp educated, honorable, responsible physicians as inhuman bigots, because they refuse to consult with every legally qualified practitioner.

NEW DEPARTURE IN THE BOSTON MEDICAL LIBRARY ASSOCIATION.

FOR some time past it has been urged upon the Executive Committee by members of this Library Association, that it would be a most desirable thing to add a circulating department to the library, and the following plan has been suggested and finally adopted by the committee: A certain number of new books, to be carefully selected and purchased, are to be loaned to members on these conditions: —

This volume is for home-reading, and may be kept by any member for a period not exceeding ten days, at the rate of five cents a day. If retained longer than the ten days allowed, the charge will be ten cents for each and every day thereafter. Every book must be entered on the librarian's book before being taken from the library.

There are now a small number of books ready for circulation, and the committee would be very glad to receive recommendations from the patrons to purchase particular books from time to time so that all tastes can be suited.

The endeavor will be made to select good standard books, which would have a general circulation, and a few that gentlemen would not care to buy for their own libraries, but would like to consult. It is justly thought that the establishment of this department will greatly add to the usefulness of the library, and that it will be so well patronized that it can be much enlarged, perhaps eventually be extended to the circulation of periodicals. It is intended that these books, after a certain period, shall be placed on the shelves of the general library. The advantages to those availing themselves of this department will be an opportunity, at a small expense, to read the latest work on any subject, and if any notes or memoranda are taken the reader may be sure of an opportunity to again consult the book. The Association, on the other hand, may profit by this plan of procuring new books, as it as yet has no endowment for this purpose, and hopes to gain enough from the fees to pay a part, at least, of the original cost.

To carry on the work the committee has appropriated a certain sum, and is guaranteed against any loss by a public-spirited and generous member of the Association. From the same gentleman a gift of a handsome Danner revolving bookcase has been received, which will hold three or four hundred volumes. With these facilities the library will doubtless be able to purchase and circulate all the new medical works as they appear, at least those in English.

AN ITALIAN HOSPITAL IN NEW YORK.

EVER since the death of Garibaldi the erection of some suitable memorial in his honor has been contemplated by the Italian citizens of New York. At first it was proposed to place a statue on the site of his former dwelling on Staten Island, but at the suggestion of the Chevalier G. F. Secchi de Casali, editor of *L'Eco d'Italia*, it has now been decided to found an Italian hospital in New York instead. The plans for the building, as drawn up by Mr. W. H. Wood, the architect, have already been accepted, and the work of erection will be begun as soon as a suitable site has been secured. When entirely completed, the hospital will have a front of one hundred feet and a depth of two hundred feet; but it is not proposed to put up such a large structure at first. The permanent front will be erected, and in the rear of it there will be temporary buildings which can be removed at any time that it is deemed advisable to complete the hospital according to the original design.

The building will be of Italian architecture, the front being of stone in two colors, and the rear and side walls of brick. A handsome colonnade will support the portico, and a bust or statue of Garibaldi will be placed in a niche above the entrance. For the interior trimmings the architect is at present experimenting with a new material designed to take the place of wood for inside work. It is made of clay rolled in sheets and mixed with sawdust. After being baked in a kiln the sheets can be nailed directly to the joists of the building, no laths or plaster being required. This material can be sawed and planed in the same way as wood, and is capable of being painted and decorated. It is thoroughly damp-proof as well as fireproof, and, in addition, has the great advantage of not absorbing disease germs. The cost of the hospital when completed is estimated at $100,000, but the buildings to be erected at first will cost only $15,000.

The general wards will accommodate about fifty beds, and there will be a few private rooms for pay-patients beside. The necessity for such an institution is shown by the fact that during the year 1882 no less

than twenty-five thousand Italian emigrants arrived in New York. Many poor Italians are now sent to the city hospitals, where it is difficult to treat them successfully on account of their inability to understand or speak English. A ball was recently given at Irving Hall in aid of the project, and in March or April a fair of Italian works of art will be held for it.

DR. JOHN BROWN'S LEISURE HOURS, THIRD SERIES.

Many men leave the practice of medicine, dropping out of the ranks at various stages of progress, to turn their attention to other fields, but comparatively few of these stragglers are called to a high place in the field of literature. These few, to whom medicine has been a means, not an end, as Dr. Brown says of Locke and Sydenham, show always in their writings the effect of their earlier study of mankind from the physician's stand-point. The doctor learns from the first, almost instinctively, to analyze the actions and motives of his patients, using the objective physical phenomena of their bodies as a check upon their subjective account of themselves, in order that, even though they deceive themselves, they may not deceive their medical adviser; he does this with something of the cunning of the detective but without the severity of a judge, simply in order that the truth may enable him to play, for the time being, the part of an honest friend and counselor. As a result, the doctor's estimate of humanity is probably at once the truest and the most charitable possible, and when he becomes a writer his knowledge of humanity forms a foundation upon which he builds as the sculptor uses his anatomical knowledge, making the fleshly covering which he imitates in marble conform to the lines of the bones and muscles which underlie and outline the whole.

The training of a physician can no more make an author than a knowledge of anatomy can make a sculptor, though the latter is an essential part of a sculptor's education, and the former adds to the writings of men fortunate enough to possess it a certain flavor, the charm of which is recognized by many beside their medical brethren. This charm is found to perfection in the writings of Dr. Holmes and Dr. John Brown (each of whom warmly admired the other), and the publication in America of the third series of Spare Hours is the occasion of these few remarks.

This volume contains the more purely professional papers originally published in the *Horæ Subsecivæ*, where many of us became familiar with them years ago. They were excluded from subsequent editions as too professional for general readers, — not medical enough for the doctors, and too medical for their patients, as the author himself says of them, — to be afterwards united in this single volume.

Not every one will agree with all he finds in these essays. Many will differ most emphatically from Dr. Brown in his ideas in regard to free competition in medicine, for instance; but all must feel that the ideas are those of a singularly honest man, whose views of life were the highest, and who was uninfluenced by any sordid motive.

In many portions of the volume the author dwells with emphasis upon medicine as an art. He has a way of considering the profession most decidedly as a means for the relief of suffering. The general tendency of his writings "being counteractive of the purely scientific and positive, or merely informative current of our day." Not that he undervalues in the least the scientific progress of the age. He is too much of an optimist to do so, but he evidently feels the loss to the student of the practical education gained under the old apprenticeship system, and desires to warn against the possible evils of the present system of teaching in classes. It is a desire to enhance the doctor's usefulness in his direct relations with suffering rather than to confine him to a narrower sphere, for few indeed can feel that they have done all that Dr. Brown advises the young doctor to do while waiting for his cases; for the man who has "fed, enlarged, and quickened his whole nature" in accordance with the doctor's prescription ought to be able to associate on terms of equality with heroes and demigods if not with the more select circle of Olympian deities.

The chief charm of the present volume lies in the history of medical men, some of whom would be unknown to us, on this side of the water, but for Dr. Brown's affectionate tribute.

The few words in regard to Dr. Adams, of Banchory, *doctissimus medicorum Britannorum*, the longer account of Dr. Marshall and his efforts in behalf of Military Hygiene, his loving tributes to Mr. Syme, present to us the striking points in their lives in a manner sure to enlist our sympathy and enhance our ideas of the possible grandeur of a physician's self-sacrificing life. Their characters are evidently drawn by the same pen that told the tale of Rab and Pet Marjorie, and one reason at least that the various individuals whose lives are given in this book are less famous than those two is simply that they were neither dogs nor little children, but only men.

These essays are marked by the same characteristics that made the better known writings so popular. They combine at once the flavor of the classics, the inspiration of devout religious feeling — something the same in kind, though as different as it is like, as inspired the literary achievements of Bunyan, — an intense human sympathy, rendered intelligent by a physician's training, with a good humor which sees the best in everything, and makes the most of it, while a sprinkling of broad Scotch adds a spice no other dialect affords.

MEDICAL NOTES.

— We have received from the Superintendent of Health of the city of Providence the returns of mortality for the year 1882. The deaths were 2242 as against 2145 the previous year. Diphtheria shows a reduction in its mortality from 116 in 1881 to 48. Typhoid fever, however, caused in 1882 141 deaths,

103 more than in 1881. This was, in fact, the most important disease of the year. It was epidemic for a few weeks after the 25th of October, and the number of deaths reported from it was 59 greater than was ever before reported in the city in any one year. There was no case of small-pox during the year 1882, and the last death in the city from this disease was in July, 1875; indeed, there has been only one death from small-pox in Providence since May, 1873, nearly ten years.

— A case has recently come under our observation of an elderly man who was etherized for the amputation of a toe, which had been crushed. On coming out from his anæsthesia he was observed to have left hemiplegia. He presents physical signs of mitral disease, though he never has had any cardiac symptoms, nor any other disease previous to his injury. In the two or three months which have elapsed the paralysis has not materially improved, and the limbs are now suffering from contraction.

— The daily press reports the arrest of a so-called "doctor" in Worcester for causing the death of a lady at West Boylston January 14th. He had been prescribing for her for bilious and typhoid fever without success. He then claimed that she was suffering from complaints incident to her sex, and treated her with kerosene oil, giving her three sweats, which raised all the skin on her body to a blister, and it came off on her back. She lived a week in terrible agony and died. An autopsy showed the cause of death to have been the application of kerosene, and the attendant was accordingly arrested on a charge of manslaughter.

NEW YORK.

— On the 10th of January a bill for the protection of alleged lunatics was brought before the Legislature by Mr. Hodges, of Brooklyn, some of the provisions of which are as follows: No person shall be incarcerated in any public or private asylum, or elsewhere, on the grounds of insanity, lunacy, or unsoundness of mind, until the fact of his insanity has been determined by a jury, upon a trial in a court of record. Violent lunatics may be confined temporarily in the manner now provided by law, until a trial can be had before a jury. Upon a petition setting forth the insanity of a person, accompanied by the affidavits of two reputable physicians, the judge of any court of record may order a trial to be held. The trial and other proceedings shall be conducted as in civil actions so far as applicable; except that the trial, when in readiness to proceed, shall be heard summarily, without reference to the calendar of the court. All fees and costs shall be paid by the petitioner, who shall be reimbursed out of the lunatic's estate, provided the fact of insanity be found. The punishment for securing the incarceration of a lunatic otherwise than according to the provisions of this act, to be a fine of $100, or imprisonment for not more than one year, or by both fine and imprisonment.

— At a meeting of the Medico-Legal Society, held January 24th, Dr. Edward C. Mann read a paper entitled A Plea for Lunacy Reform, in the course of which he said: "We have to-day the false principles that personal liberty is of little consequence, and that if a man or woman is insane, it is of itself a sufficient reason for confining them in a lunatic asylum. These false principles are implied in the statutes, they are acted upon, and judges even are misled by them. . . . When persons on this border-land of insanity have stepped over the debatable line, I think that the most deplorable results have often occurred when such cases have been confined in asylums, and that incurable insanity may have been the result of such a course on the part of friends. Persons are often admitted to asylums to save those who are dependent upon them from some annoyance, when they would have been more comfortable and would have had a better chance of recovery in their own homes." The commission of the Society in regard to the amending of the lunacy laws have submitted a report in which they recommend, among other points, that no person shall, as is now the custom, be committed to a lunatic asylum upon the simple certificate of two physicians under oath; that any physicians who give testimony for or against an alleged lunatic shall be experts on the subject of insanity; that all examiners in lunacy be selected by a competent tribunal; that legal provisions be made for allowing any person incarcerated in a private or public asylum to write to his friends or to his counsel, and that once in every six months an examination into the condition of the patients in asylums shall be made by competent experts.

— The Fire Commissioners have sent a letter to the chief engineer of the St. Louis Fire Department requesting that the instructor of the St. Louis Life-Saving Corps be permitted to come to New York and organize a similar corps among the firemen in the latter city. At the request of Commissioner Puzzey, the Board of Fire Commissioners recently decided to try the experiment of providing light scaling ladders, fire belts, life ropes, and other similar apparatus for the use of firemen. In using one of these scaling ladders, which are about twenty feet long, the fireman ascends from window to window of a burning building by fastening the hook with which it is provided in the sills. Around his waist he wears a wide canvas belt with a steel clasp in front of it, which he can fasten to a rung of the ladder, and thus have his hands free; and he also has around his neck a coil of rope, by means of which, having secured one end of it to any firm support, he can descend to the ground. A circular has been posted in all the company quarters inviting firemen who consider themselves physically qualified to volunteer as members of the proposed corps. The training school will be established at the new fire engine house in Ninety-seventh Street, near Tenth Avenue, and as rapidly as the volunteers become skilled in the use of the life-saving apparatus they will be assigned to hook and ladder companies.

— The twelfth annual dinner of the Alumni Association of the Medical Department of the University of the city of New York was held at Delmonico's on the 24th of January. Dr. T. R. Varick presided, and

addresses in response to various toasts were made by the Rev. Dr. John Hall, Dr. Alfred L. Loomis, Mr. Brennan, Commissioner of Charities, Noah Brooks, Esq., Rev. William M. Taylor, D. D., F. N. Bangs, Esq., President of the Bar Association, and Dr. A. A. Smith. At a business meeting before the dinner the following officers were elected: President, Dr. A. E. Macdonald; Vice-Presidents, Drs. W. A. Hammond, J. W. S. Greeley, W. E. Ford, S. J Clark, C. G. Jarvis, and G. J. Fisher; Treasurer, Dr. C. Dixon Varley; Secretary, Dr. F. R. S. Drake.

PHILADELPHIA.

— The meeting of the Association for the Protection of the Insane and the Prevention of Insanity was held in this city last week. A report of the proceedings appears in another column. One of the most important measures passed was the appointment of a committee to prepare a better title for the organization.

— The commissioners appointed by Governor Hoyt have prepared a bill for the protection of the insane, which will, in all probability, be presented at the present session of the Legislature. It provides for a control board, to be composed of the Board of Public Charities and three others, to be named by the Governor. It requires that all pay places where insane patients are treated shall take out license, under regulations prescribed by this committee, for the conduct and control of such establishments. The committee have power to enforce their regulations by suspending the license upon disregard of their rules, and such withdrawal of license lays the offending parties open to a charge of misdemeanor. The act also provides for the regular visitation of such institutions, and deals with the criminal insane, and provides that such persons, when pronounced cured, shall be turned over to a place of custody, and not discharged upon the community without legal release.

— The third annual meeting of the Philadelphia Academy of Surgery was held January 8, 1883, at which the President, Prof. S. D. Gross, occupied the chair. Dr. William Hunt, the orator of the occasion, took for his subject a review of the achievements of surgery for the past year, paying especial attention to Professor Esmarch and antisepsis. The communication of Esmarch upon the case of President Garfield was taken up and critically discussed. Notwithstanding the professor's statement that the gun-shot wound of the vertebra was not necessarily fatal, he said he had no hesitation in challenging him to produce a single human specimen illustrating recovery, from the dissecting rooms or museums of America or Europe. With regard to sepsis and wound infection, he considered that the poison was in the patient rather than in the atmosphere, and cited an instance in which he was himself rendered toxæmic by the fetid gas issuing from an abscess which he lanced. This instance was reported in the Pennsylvania Hospital Reports in 1868. He concluded that it was not what went into the man but what came out of it poisoned both patient and surgeon. In the details of the President's case he showed that some of the professor's premises were incorrect, and his conclusions hasty. In particular he ridiculed the idea of comparing the slight superficial wounds of the Emperor with a few bird shot with the mortal wound of the vertebra and splenic artery in the case of the late President. With reference to antisepsis, he compared micrococci to maggots, and said, "Having noticed wounds healing kindly under a mass of maggots, I reflected that they were scavengers, eating only dead material, and so converting harming matter into harmless living substance. We have to get rid of them, it is true, because they will *persist* in getting into *wrong* places, and so giving infinite amount of trouble." He asks, "Now are the micro-organisms, of which we hear so much, any more than consumers of dead material, serving a beneficent end so long as they do not get into *wrong* places? Molecular death is going on continually in all living tissues. In the nice balance of perfect health the results are removed so completely through the blood and lymph channels and by other means that there is no accumulation. When, however, disturbance arises, as inflammations, for example, from any cause, abundant necrotic products are the consequence, and these accumulate faster than they can be removed. Then come in the migrating micro-organisms. It is a question of food, and is consonant with what we know of the movements of hosts of higher animals and plants. What is of more importance is that these organisms get into *wrong* places, where, accumulating with great rapidity, they help to choke further and irritate what has already started on an evil course, and so they become secondary and very fruitful causes of disease. We may see from Formad's views how scrofulous subjects with narrow lymph channels are more readily affected than others. To my mind there is no positive proof as yet of the organisms being the specific and primary causes of disease."

After the lecture, which was attentively heard by a large audience of ladies and gentlemen, a reception was held in the Museum of the College of Physicians, and a fine microscopic exhibition held.

— At Dr. DaCosta's clinic a case was recently shown of a man who had taken six drachms of chloral within two hours, but who recovered after electricity, artificial respiration, and strychnia injections.

MEDICO-LEGAL NOTES.

THE PELTZER TRIAL.

The *London Medical Record* gives a résumé of the Peltzer trial, in which some interesting and important facts regarding the post-mortem evidence as to the cause of death in gun-shot wounds were brought out. The Peltzer brothers, Armand and Léon, were accused of the murder of M. Bernays, a well-known barrister of Antwerp, with whose wife Armand was suspected of a *liaison*. At the instigation of Armand, Léon, it is supposed, shot M. Bernays, who was unwittingly entering a room whither he had been enticed

for that purpose. The body was discovered eight days after death, sitting in an arm-chair, with no blood upon the clothes, but with a pool of some nine ounces upon the floor. The post mortem was made eleven days after the murder. At the trial, Stienon, the examiner, testified that the cause of death was a wound in the nape of the neck, which was perfectly clean, without any burn. The ball had gone through the neck from left to right, slightly ascending, and perforating the skull. The principal part of the projectile was found in the right temporal (middle) lobe of the brain. On the body were stains of blood and cadaveric lividities. The blood stains were in the nape of the neck and on the right side of the head. On the nostrils and moustache were streaks of blood. There were lividities on the right leg and fore-arm. No blood was found in the pharynx. The wound in the nape of the neck could not have bled much externally. The bleeding had been internal and through the nose. There was little blood on the clothes of the deceased. A spot on the carpet contained nine ounces of blood. There was a foot-print, as he alleged, in this spot, not produced by the deceased. Experiments made for the purpose showed that the foot-prints could not have been produced earlier than two hours and a half after the blood had flowed on to the carpet, and probably it was twenty to twenty-five hours afterwards. It was certain that the foot-print was not produced on January 18th, the day of the first investigation at the house, and eleven days after the death. Experiments showed that cadaveric lividities could no longer be displaced when the body had remained in the same position for twenty-eight or thirty hours; therefore the body could not have become cold in the same position as that in which it was found. It might have been moved after twenty-eight or thirty hours, but the cadaveric rigidity must be taken into consideration. The body must have been rigid after twenty-four hours. Destruction of this rigidity was possible only by tearing the muscles, and no muscles were torn; therefore it was probable that the moving of the body had been effected after cadaveric rigidity had disappeared, which would happen after sixty or seventy hours. It followed that the body must have been moved five days after the crime. The blood-clot on the carpet was irregular in shape, there being no blood in the centre, and the foot-print was at the side. Death had doubtless been instantaneous, and experiments showed that the shot had been fired at a distance of four inches from the wound, though there was no blackening. The clothes of the deceased were in perfect order, and there was no evidence of a struggle having taken place. Léon had indicated a spot where the shot was fired (in a quarrel, as he now claimed), but it was impossible that his victim could have been on that spot, as in that case the blood would have flowed all over his clothes, which was not the case. Bernays had evidently fallen against the corner of a writing table, as was indicated by a slight wound on the temple, and had then rolled on to the floor. Probably the deceased was shot whilst stooping his head, as many people do instinctively on entering a room. Inside on the door were some drops of blood, spurted on it when the wound was inflicted. The victim had bled through the nose for five or ten minutes after death. If the assassin had raised the head of Bernays, the blood would have flowed on to the clothes, which were free from blood. The foot-print on the blood-clot on the carpet had probably been made by a boot of Armand's, with which the mark corresponded. The body had not been moved sooner than from forty to sixty hours after death. This was the summary of Stienon's evidence, and he was confirmed by Vleminella.

The only points at variance with this testimony which were maintained by experts for the defense were that the impression on the blood upon the carpet had been made by a knee and not a boot, and that it might have been made in ten or fifteen minutes after the blood had flowed. Hence it might have been caused, as Léon stated, when he knelt to raise the head of the deceased to render him assistance. Cadaveric lividities, these witnesses testified, permitted no conclusions to be drawn twelve days after death, as they were then accompanied by putrefaction. The blood they believed to have flowed from the neck and not from the nose. The brothers Peltzer were both convicted.

Miscellany.

DR. GOODELL ON STERILITY AND PELVIC PERITONITIS.

IN a recent clinical lecture,[1] Dr. Goodell, speaking of a case of anteflexion with stenosis causing dysmenorrhœa and sterility, says: —

"From my observation I should say that marriage is poison to a woman unless she has children. Nature intended that the womb should by pregnancy have a respite from the monthly congestions of the menses. At the end of nine months the woman gives birth to a child and suckles it, and this also gives rest to the womb. If now there is a stenosis of the cervical canal, she cannot become pregnant; the congestion grows worse at each period, and finally becomes continuous and pathological. Marriage adds to this chronic condition the congestions resulting from the marital relations, as coition, etc., and things go on from bad to worse, until the woman may at last become a confirmed invalid."

His treatment of the stenosis was by rapid dilatation, which he strongly recommends as against a cutting operation. With the exception of two cases in which the os was torn (not, however, with any ill results), he has never had any accident in one hundred and thirty recorded cases of dilatation, while he lost a patient from the cutting operation, and believes that many women have died from that treatment.

Regarding a case of pelvic peritonitis with fixation, he remarks: —

"Fixation is not a good term; but, as I have not succeeded in coining a better word, I still use it. Some one has made the beautiful simile that the womb in its natural condition is like a ship riding at anchor which moves with every change in the current, and responds to every change in the direction of the wind;

[1] Philadelphia Medical Times, January 13.

so the womb, steadied loosely by its ligaments, responds to every movement of the body, — to every inspiration and expiration. It is needful that it should be so; for, if the womb were fixed, the male organ would during coition cause severe pain, and might indeed perforate the vagina, as has been recorded in one or two instances. A cold winter night comes, and the water in which the ship has been freely floating freezes, and the vessel no longer moves with the current. So it is with the womb."

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 27, 1883.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from				
				The Principal "Zymotic" Diseases.	Lung Diseases.	Diphtheria and Croup.	Scarlet Fever.	Small-Pox.

Deaths reported 2705 (no report from Chicago): under five years of age 785: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 549, consumption 407, lung diseases 388, diphtheria and croup 201, small-pox 97, scarlet fever 76, typhoid fever 49, diarrhœal diseases 27, measles 23, cerebro-spinal meningitis 18, whooping-cough 18, erysipelas 18, malarial fevers 16, puerperal fever eight. From *typhoid fever*, Philadelphia 10, Pittsburg nine, New York five, Boston, District of Columbia, and Providence three each, St. Louis, Baltimore, Cincinnati, New Orleans, and Buffalo two each, Brooklyn, Lowell, Fall River, Lawrence, Holyoke, and Malden one each. From *diarrhœal diseases*, New York nine, New Orleans eight, Boston four, Baltimore two, Brooklyn, Cincinnati, Nashville, and Marblehead one each. From *measles*, New York 14, Cincinnati four, Brooklyn, Boston, New Haven, Holyoke, and Brookline one each. From *cerebro-spinal meningitis*, New York five, New Orleans three, Brooklyn and St. Louis two each, Boston, Buffalo, Providence, Fall River, Taunton, and Waltham one each. From *whooping-cough*, New York and Brooklyn three each, Philadelphia, St. Louis, and Pittsburg two each, Cincinnati, Buffalo, Providence, New Haven, Nashville, and Northampton one each. From *erysipelas*, New York six, Philadelphia, Cincinnati, and Buffalo two each, Brooklyn, Boston, Baltimore, and Pittsburg one each. From *malarial fevers*, New York five, New Orleans four, Brooklyn three, St. Louis and Baltimore two each. From *puerperal fever*, Boston three, St. Louis two, Cincinnati, Milwaukee, and Holyoke, one each.

Two hundred and thirty-six cases of small-pox were reported in Baltimore, Cincinnati four, Pittsburg four, Boston one; diphtheria 39, scarlet fever 21, typhoid fever three, in Boston; scarlet fever 16 and diphtheria six in Milwaukee.

In 37 cities and towns of Massachusetts, with a population of 968,915 (population of the State 1,783,086), the total death-rate for the week was 20.32 against 19.79 and 21.58, for the previous two weeks.

In the 28 towns of England and Wales, with an estimated population of 8,620,975, for the week ending January 13th, the death-rate was 22.4. Deaths reported 3708: acute diseases of the respiratory organs (London) 361, whooping-cough 107, scarlet fever 77, measles 68, fever 54, diarrhœal diseases 32, diphtheria 18, small-pox (London seven) seven. The death-rates ranged from 9.1 in Derby to 33.7 in Liverpool; Brighton 14.1; Leicester 18.5; Nottingham 19.9; London 20.7; Birmingham 22; Sheffield 23.1; Newcastle-on-Tyne 24.4; Leeds 26; Plymouth 27.8; Manchester 28.9. In Edinburgh 17.9; Glasgow 30.6; Dublin 29.4.

For the week ending January 13th, in the Swiss towns, population 494,390, there were 31 deaths from consumption, lung diseases 25, diphtheria and croup 13, diarrhœal diseases 12, scarlet fever three, typhoid fever three, whooping-cough one. The death-rates were, at Geneva 15.4; Zurich 20; Basle 15.1; Berne 30.5.

The meteorological record for the week ending January 27th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

[1] O., cloudy; C., clear; F., fair; G., fog; H., hazy; S., snow; R., rain; T., threatening.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 26, 1883, TO FEBRUARY 3, 1883.

WATERS, WILLIAM E., major and surgeon. Detailed as member of Army Retiring Board to convene at Fort Porter, Buffalo, N. Y., February 2, 1883. Paragraph 1, S. O. 21, A. G. O., January 25, 1883.

KILBOURNE, HENRY S., captain and assistant surgeon. The leave of absence granted December 21, 1882, Department of Dakota, is extended two months. Paragraph 3, S. O. 24, A. G. O., January 29, 1883.

PAULDING, H. O., captain and assistant surgeon. Granted leave of absence for one month, to take effect on or about the 1st of February. Paragraph 1, S. O. 11, Department of the Platte, January 27, 1883.

PRICE, CURTIS E., captain and assistant surgeon. Detailed as member of Army Retiring Board to convene at Fort Porter, Buffalo, N. Y., February 2, 1883. Paragraph 1, S. O. 21, A. G. O., January 25, 1883.

WOOD, MARSHALL W., captain and assistant surgeon. At expiration of present leave of absence relieved from duty in the Department of the East. Paragraph 1, S. O. 15, Department of the East, January 26, 1883.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE HOSPITAL SERVICE, OCTOBER 1, 1882, TO DECEMBER 31, 1882, *continued.*

HEATH, W. H., passed assistant surgeon. Granted leave of absence for fourteen days. December 28, 1882.

PORTER, F. D., passed assistant surgeon. To inspect keepers and crews of the Life Saving Service. October 5, 1882.

To proceed to Evansville, Ind., for temporary duty. November 21, 1882.

To proceed to Charleston, S. C., and assume charge of the service. December 21, 1882.

O'CONNOR, F. J., assistant surgeon. To proceed to Norfolk, Va., for temporary duty. October 14, 1882.

To rejoin his station (Detroit). November 4, 1882.

WHEELER, W. A., assistant surgeon. Relieved of duty at Charleston, S. C., and placed on waiting orders. December 22, 1882.

ARMSTRONG, S. T., assistant surgeon. To examine keepers and crews of the Life Saving Service. October 5, 1882.

BENNETT, P. H., assistant surgeon. To examine keepers and crews of the Life Saving Service. October 5, 1882.

AMES, R. P. M., assistant surgeon. Granted leave of absence for twenty-one days. November 23, 1882.

DEVAN, S. C., assistant surgeon. To examine keepers and crews of the Life Saving Service. October 13, 1882.

To inspect unserviceable property at the San Francisco Marine Hospital. October 20, 1882.

KALLOCH, P. C., assistant surgeon. To inspect keepers and crews of the Life Saving Service. October 5, 1882.

SUFFOLK DISTRICT MEDICAL SOCIETY. THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE will meet at 19 Boylston Place, on Wednesday evening, February 14th, at 7.45 o'clock. The following papers will be presented: Dr. F. A. Harris, The Medical Evidence in the Malley Trial. Dr. B. O. Kinnear, Explanatory Remarks upon Neuro-Dynamic Medicine, with Cases. Dr. G. H. Lyman, A Case of Embolism of the Left Middle Cerebral Artery. Dr. C. E. Wing, A Case of Inverted Uterus treated by the Modern Methods. Dr. M. H. Richardson, A Case of Empyema.

ALBERT N. BLODGETT, *Secretary.*

THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT will meet Monday, February 12th, at eight P. M., in the Medical Library. Dr. S. G. Webber will read a paper on Some Ocular Symptoms associated with Lesions of the Pons Varolii and Neighboring Parts.

EDWARD M. BUCKINGHAM, M. D., *Secretary.*

BOOKS AND PAMPHLETS RECEIVED. — The Value of Graduated Pressure in the Treatment of Diseases of the Vagina, Uterus, Ovaries, and other Appendages. By Nathan Bozeman, M. D. New York. (Reprint.)

House Drainage and Sanitary Plumbing. By William Paul Gerhard, Civil and Sanitary Engineer. New York: D. Van Nostrand. 1882. (A. Williams & Co.)

The Management of Chronic Inebriates and Insane Drunkards. By Albert N. Blodgett, M. D. Boston. 1882.

The Hospital Treatment of Diseases of the Heart and Lungs, with over three hundred and fifty Formulæ and Prescriptions, as exemplified in the hospitals of New York city. By Charles H. Goodwin, M. D. New York: Charles H. Goodwin, M. D., 245 West Fifty-Third Street.

A National Bankrupt Law. Speeches by Hon. George F. Hoar, of Massachusetts, in the Senate of the United States, June 23, and December 8 and 9, 1882.

The Structure of the Muscles of the Lobster. By M. L. Holbrook, M. D., New York. (Reprint.)

The Termination of the Nerves in the Liver. By M. D. Holbrook, M. D. New York. (Reprint.)

Transactions of the Medical Society of the State of New York for the Year 1882. Published by the Society.

Address delivered before the American Academy of Dental Science, at their Fifteenth Annual Meeting, held in Boston October 25, 1882. By Frank Abbott, M. D.

A Case of Melanosis. By William H. Tubbs, M. D. Cincinnati, O. (Reprint.)

Medical Society of the State of Tennessee Transactions. 1882. Forty-Ninth Annual Meeting.

Massage. Its Mode of Application and its Effects. By Dr. Douglas Graham. Boston. (Reprint.)

A Large Fibro-Cyst of the Uterus and Ovarian Cystoma coexisting with Pregnancy; Operation; Recovery. By Walter Coles, M. D. St. Louis. (Reprint.)

Variola. A Series of Twenty-One Heliotype Plates illustrating the Progressive Stages of the Eruption. Boston: Samuel A. Powers. 1882.

Fourth Annual Report of the State Board of Health of Illinois. Springfield. 1882.

Lectures.

OPENING LECTURE ON DISEASES OF CHILDREN AT THE POST-GRADUATE MEDICAL SCHOOL, NEW YORK.[1]

BY MARY PUTNAM JACOBI, M. D.

II.

As we approach the birth point in the survey of the child's history, we are made aware of the persistent influence of many conditions which have dominated fœtal and embryonic life. The process of cleavage, the process of curvature, the principle of inequality in the growth of parts, and that of mutual limitations of growth, govern, taken together, the course of embryonic evolution. They constitute a set of mechanical conditions which, in continuation with the one vital process of continuous growth, suffice to produce the marvelous results of that evolution. The mechanical influence, principally of pressure, is exerted in the first place by the membrane investing the embryonic mass, or, in other words, by the external medium; in the second place by the parts of the organism reciprocally upon one another. Throughout childhood this special susceptibility to mechanical influences persists, and, as in embryonic life, these are exerted first, by the external medium upon the growing organism, second, by the parts of that organism reciprocally upon each other. This is a fundamental fact which offers the key to many of the peculiarities of infantile pathology, as we propose to show in detail.

The fertile results which may be obtained from the simple influence of continuous pressure exerted upon masses continually increasing in size is remarkably shown in the process of cleavage. This is not primary or self-determined, but is brought about, first, by the pressure of the investing membrane upon the protoplasmic masses, second, by the retractile force of these masses themselves. The segmentation of the ovum — the first step in its development after fecundation — offers the first example of this process. This diagram, enlarged from Kölliker, exhibits the segmentation of the ovum of an ascaris. The second example is found in the cleavage of the blastoderm into three layers: the ectoderm, entoderm, and mesoderm. It is shown in this diagram. The formation of the cleft for the spinal column, of those for the pleuro-peritoneal cavity and pharynx, of the bronchial clefts, the segmentation of the provertebræ, and finally the segmentation of the limbs, are all important illustrations of the process of cleavage, determined in each case by the double mechanism above described.

After birth no cleavage process ever occurs, but we encounter several pathological conditions dependent on errors of cleavage, on its excess, more rarely on its deficiency, most often on the persistence of clefts, which, in the normal course of development, should have become closed. A complete cleavage of the ovum, previous to the differentiation of its parts, results in a twin pregnancy. It implies an excess of formative material, but may be considered as the first step towards a monstrosity. (Ahlfeld.) Partial cleavage of the caudal or cephalic extremity, or of both, results in the development of different kinds of double monsters. Excess of cleavage at the extremity of the limb buds causes supernumerary fingers or toes. I here show you a child presenting such a deformity. The process of cleavage, continuing after the different fingers had been differentiated, has split up the thumb segment into two unequal parts. In the larger or internal segment the two phalanges continue in a straight line with the metacarpal bone. The smaller external segment stands out at an angle with the metacarpal bone, being apparently articulated with a facet on its distal and outer extremity.

Failure of cleavage determines various degrees of apparent fusion of parts, a deformity again principally observed in the limbs. Web fingers or toes constitute the lightest grade of this deformity. The fingers are well formed, but connected by a fleshy membrane, not difficult to divide, but whose parts show an almost incoercible tendency to grow together again. The fingers may, however, be fused into a solid mass; the two lower extremities may remain united in a species of tapering tail, and constituting the viable monster known as the siren.

The most numerous malformations, however, connected with the process of cleavage are those which result from a failure to close of a cleft destined only for temporary existence. Thus persistence of an extensive portion of the dorsal cleft determines a hemicephalus, of a more limited portion, with protrusion of the spinal membranes, a spina bifida. Of the latter malformation I here exhibit to you a living specimen. The hernial tumor is situated, as you will notice, in the seat of election, the lumbar region, the vertebral arches being here entirely deficient. The greater frequency of spina bifida in this region is explained by the fact that closure of the dorsal cleft is effected from above downwards, as is shown in this diagram. Hence the lumbar region remains open for the longest time.

I defer more detailed study of this interesting case to another occasion. I merely point out here that the hemispheric tumor, as large as half of a large orange, is deprived of skin, and its thin, membranous surface superficially ulcerated; that the child, which is seven months old, though enjoying fair health, is much emaciated, and, for a month or two, has exhibited the symptoms of a chronic internal hydrocephalus; finally, that the lower extremities are congenitally paralyzed, and both feet are in marked talipes calcaneus. It is probable, therefore, that a dropsy of the central canal of the cord exists, which has gradually extended to the ventricles of the brain, of which the central canal is normally the continuation.

On the anterior surface of the body malformations are frequently encountered, which result from failure of union of the lateral segments of the body. Hare lip and cleft palate (the deformity is shown in this baby) are caused by the failure of fusion between the superior maxillary processes, with the frontal or intermaxillary process. The relative position of these parts at the eighth week of fœtal life is shown in this wax model. The deformity caused by the interruption, between the ninth and tenth week, of the normal process of fusion, constitutes ninety-nine per cent. of all cases of malformation of the face.

Fissure of the sternum, or, from partial failure to close of the abdominal plates, umbilical hernia, and vesical ectopia, may be mentioned as further illustrations of malformations dependent on abnormal persistence of cleavage. On the lateral walls of the fœtus partial persistence of the bronchial clefts leads to certain congenital cysts of the neck; while within the

[1] Concluded from page 123.

pleuro-peritoneal cavity, though the abdominal plates be closed, failure in the development of one lateral half of the diaphragm necessitates the fatal accident of diaphragmatic hernia.

"It is no explanation," observes Ahlfeld, of these malformations, "to say that they result from an arrest of development. The question is, What has caused such arrest?" and the author assigns five principal causes: first, an insufficiency of formative material; second, pressure from without of too tense amniotic membranes, together with, possibly, deficiency of amniotic liquor; third, pressure from within of dropsical effusions; fourth, interposition, or even adhesion of amniotic folds; fifth, prolapse of some part between the segments destined for fusion.

The process of curvature is as important as that of cleavage in embryonic evolution. To understand its causation and consequence, His advises the student to take a cylinder of wax and slowly press down one extremity towards the other, in the long axis of the cylinder. This will cause a bulging out on each side of the compressed extremity, and the development of a transverse cleft running across it, and connecting the bulging points. The cleft becomes more apparent when a hollow cylinder of india rubber is used, instead of a solid cylinder of wax, and the extremity is curved forward at the same time that it is compressed. It then not inaptly represents the buccal cleft, which develops across the cephalic extremity of the embryo, at the moment that this undergoes the so-called "cephalic curvature" forwards. This curve is shown on this wax model, and also on this diagram enlarged from His. Not only the buccal cleft and cavity, but the lense cavities are formed by this same mechanism; the oculo-nasal cleft is deepened, the forehead acquires prominence, and lateral folds or ridges are thrown up in the neck, between which the bronchial clefts are destined to appear.

The cephalic curvature is observed only in the embryos of mammalia, birds, reptiles; and these alone exhibit the development of the amniotic fold over the cephalic extremity, known as the amniotic hood. His derives the first of these nearly contemporaneous processes from the second, showing that the pressure of the amniotic fold upon the constantly growing head of the embryo necessitates the forward curvature of the latter. The mechanical influence of pressure, combined with the single vital process of continuous growth, thus again suffices to determine most complex results.

The same influence of external pressure is continued after birth, throughout infancy and childhood, and, indeed, until all portions of the organism have become solid enough to resist it. The physiological curves of the spinal column are developed by the weight of the head and shoulders when the child begins to assume a sitting and upright position. When the weight to be supported increases out of proportion to the process of consolidation in the vertebræ, and if it become unequally distributed, the pathological curves of scoliosis are formed. The fact, recently established by Beneke, of the great increase in the volume of the heart and lungs about the period of puberty is probably correlative with the special morbid liability to scoliosis noted for this same period. The greater size of the right lung, which has often been alleged as at least one cause of the curvature of the cervico-dorsal spine to the right, may more plausibly be considered so, when it is known that the lungs at early maturity have attained to twenty times their volume at birth. The heart, whose inclination towards the left should balance the excess of weight of the right lung, only increases twelve or thirteen times its original size. But it has been further noted by Beneke, that, in anæmic and phthisical persons, the development of the heart which should take a sudden leap forward during the year of the establishment of puberty remains insufficient, and does not attain the size which is needed as a make-weight to the lung.[1] It is precisely such persons as are most liable to the scoliosis of adolescence. They are also liable to excess of growth of the osseous frame-work of the body, out of proportion to the vigor of its viscera; hence, again, to an excess of weight to be supported by an abnormally soft spinal column.

The more extensive softening, especially of the intervertebral disks, caused by rachitis, occurs at an earlier period, while weight is evenly distributed, and the influence of sitting postures, right arm exercise, etc., have not yet been experienced. The curve, then, instead of being lateral and partial, is general, is in cyphosis. A case of this kind in an extremely rachitical boy of five years old was sent to my clinic as paralyzed. He indeed could not walk nor hold his trunk erect; but upon being supported in a plaster jacket he was able to do both, and under the use of cod-liver oil, iron, and lime, entirely recovered.

Depression of the ribs, of the cranial bones (craniotabes), curvature of the femurs and tibiæ, are all well known results of the influence of pressure steadily exerted upon the softened bones of rachitical children. The lower limbs frequently exhibit the characteristic curvatures before they have ever borne the weight of the body. The deformity seems, then, to be attributable to the inability of the extensor muscles to correct the attitudes of flexion first assumed by the limbs.

Another interesting illustration of the influence of weight, or the pressure exercised by it, is offered by the deformities consequent upon infantile spinal paralysis. A certain number of authors have explained these deformities by the persistent terms of non-paralyzed muscles whose antagonists had been paralyzed. In reality, however, the deformity is due to the influence of a weight which tends to press the limb in a certain direction, from which the paralyzed muscles are unable to withdraw it. Rachitic paresis of muscles or softness of ligaments have the same result. The weight of the body pressing in the direction of the long axis of the femur from above downward, and from without inward, comes against the internal lateral ligament of the knee-joint, and being insufficiently resisted by the contraction of muscles which should maintain the leg in a straight line with the thigh, constantly exaggerates the angle existing between these two segments until genu valgum results. Valgus of the foot is formed when similar pressure is exerted at the internal lateral ligament of the ankle-joint; flat foot when the arch of the foot is pressed down by a dead weight inadequately taken up by the elastic force of plantar muscles and ligaments.

The effects of pressure are most striking in relation to an undeveloped organism, because the part which has been deviated in a vicious direction continues to grow in that. The effect of the deviation, therefore,

[1] The influence of such defect in lowering the force of the pulmonary circulation, facilitating caseation of inflammatory products, is of course of even greater importance.

not only persists, but continually tends to increase. But all living parts, even when ceasing to increase, are subjected to a constant molecular change by the movements of nutrition, and these movements are liable to be deviated in an increasingly intense degree by the influence of even an unvarying pressure even in an adult or slowly growing part. Hence therapeutic influences of much value. Pressure and position may be utilized to promote lymphatic absorption; to change currents of circulation; to determine local atrophy. Probably the value of such mechanical agencies is as yet only imperfectly appreciated. Their power is best to be learned by studying their influence upon embryonic evolution and in the physiology and pathology of childhood.

The third fact of embryonic development which we find still potent in childhood is the inequality in the rate of growth of different parts of the organism. This unequal growth is, during embryonic life, an important factor in the formation of the folds, clefts, and curves we have just been considering. After birth, the same inequality persisting, determines a succession of phases, both in physiological function and capacity, and in morbid imminence. It is incorrect to assert that at birth the child is an entirely imperfect being. The functions of capillary circulation, of molecular nutrition, of urinary excretion, are performed with more surety and vigor than at many other periods of life. The dangers arising from novelty of function in the respiratory apparatus and the great susceptibility to cold are largely compensated by the peculiarities in the relations between the heart and the lungs. During infancy the pulmonary artery remains wider than the aorta, and pressure in the pulmonary exceeds that in the systemic circulation. Extensive obstruction to the circulation, with obstacle to the work of the right heart, occurs, therefore, less frequently than in adult life, where the conditions are reversed, and the force of the pulmonic circulation falls below that of the systemic. Hence paralysis of the heart from mechanical causes, as the obstruction to the circulation caused by pneumonia, is less liable to occur; and thus pneumonia is really a less dangerous disease in children than in adults. During fœtal life marked inequality exists in the distribution of oxygenated blood. This comes from the placenta by the umbilical vein, and, brought to the heart by the inferior vena cava, is carried directly across the right auricle to the foramen ovale by means of the Eustachian valve, that really forms a special channel for its conduction. It is this blood which reaches, almost unmixed, the left ventricle, to be thence thrown through the aorta and the vessels springing from its arch towards the cephalic extremity of the fœtus, towards the brain, and more especially the medulla, with its important cardiac and respiratory centres. These, therefore, get a special start in development. On the other hand, the venous blood returned from the head and the upper extremities enters the right auricle in front of the Eustachian valve, or channel, and, by the pulmonary artery and ductus arteriosus, reaches the descending aorta, to be distributed unmixed to the lower half of the body. This, therefore, remains retarded in development as compared with the upper half, and not only the limbs, but the lower portion of the spinal cord, with the ganglionic centres governing the limbs and the pelvic organs.

Now it is a fact that the lumbar portion of the cord and spinal column show, certainly throughout childhood, a morbid imminence superior to that of the upper portions. Osteo-myelitis, in the one, anterior poliomyelitis in the other are much more frequent in the lumbar than in the dorsal or cervical regions. We have already alluded to the predilection of spina bifida for this region, where the vetebral arches are the last to close. May we not consider all these facts as the consequences of a nutrition, defective in comparison with that of the upper nerve centres and spinal column? We may even go further and trace to such disproportion, failing to lessen, or even increasing, with advancing years, such imperfect development of the utero-ovarian system in many anæmic children as entails disease as soon as these organs enter upon function. If the maximum nutritive currents of the body only just touch par the minimum cannot fail to fall below the level of healthy vitality.

The foregoing considerations are theoretical. Practical precautions of great importance are required in the adjustment of external media to the unequally unfolding organism of the child. The adjustment of foods to the successive phases of development of the digestive organs; of effort to those of the locomotor apparatus; perhaps, most difficult of all, of action and rest to the complex phases in the development of different parts of the nervous system. It would carry us much too far to show how profoundly this principle enters into the guidance of mental development; and how much it has been overlooked until most recent times. The child's mind and body for centuries has been looked at simply as a miniature of the man's; the fact that the inter-relation of their parts was differently proportioned has, until now, been most dimly apprehended.

The final principle to which I would call your attention is that of the mutual limitation of parts. In the embryo the natural termination of the growth of any mass of cells is effected when it is brought in contact with an opposing mass, growing with equal or superior vigor. Failure in the establishment of such limiting contact results in the undue growth of the first mass of cells. An interesting illustration of such failure drawn from infantile pathology is suggested by a remark of Bouchard. This author would explain the excessive growth of the medulla, of bones in rachitis, by the defective calcification of the bones. The medullary elements, insufficiently imprisoned in calcareous envelope, are left free to develop immoderately.

Diminution in the calcareous matter of long bones, occasioned by prolonged febrile diseases, may similarly help to explain the growth of the patient, which is often observed in convalescence from such diseases. The medullary elements undergo a nutritive irritation in virtue of the febrile disease; this coinciding with a diminished resistance in the osseous envelope is liable to determine in adolescents a sudden increase of growth, which is not of good augury, inasmuch as nutritive material is thus withdrawn from nervo-muscular tissues greatly in need of repair. This same reason justifies the popular dread of "outgrowing the strength," a process frequently observed in delicate children or youth. When, moreover, with elongation of the skeleton the heart and lungs fail to grow in proportion; when, by increasing length of the neck, the brain is removed farther from the heart, and thus receives its impact of blood less forcibly, muscular weariness, anæmic headaches soon result.

These few examples may serve to illustrate a prin-

ciple whose application is probably far-reaching. It is possible that the primary reason for the development of neoplasms consists in a failure of normal tissues to limit the growth of certain elements either homogeneous or heterogenously imprisoned in the organism at birth. (Cohnheim.)

The foregoing most cursory survey briefly indicates the line of thought which seems to me most profitable to pursue in studying the diseases of children. With all considerations drawn from general pathology are to be combined those based upon the special fact of continuous growth, of unequally rapid evolution. The morbid conditions altogether peculiar to childhood are to be understood only by reference to circumstances of development. Study of disease common to children and to adults must be outlined in its main features in the latter, but then specially adapted to the former, and peculiarities explained by, again, peculiarities in the phase of development. And to thoroughly understand the meaning of developmental processes these must be studied where they are most rapid and their results most vivid and striking, namely, in the embryo and fœtus. Here may be first acquired the full conception of the wonderful flexibility of living things, of the ceaseless rush of life towards its goal; of the curve of changes so incredibly rapid at the outset, so gradually slackening throughout childhood towards the relative stability of adult existence, to finally recommence, substituting for the original increment a constant decrement of force, until the wave of life terminates in death.

DEATH FROM RUPTURE OF AN ANEURISM OF THE SPLENIC ARTERY.[1]

BY JAMES B. AYER, M. D., BOSTON.

MRS. H. was married at the age of sixteen, and one year later gave birth to a child. Up to this time she had enjoyed excellent health. When her babe was three months old she was seized with severe abdominal pain, which she attributed to thoughtlessly placing her hands in cold water. It is probable that she suffered from an attack of peritonitis at this time, though she continued to nurse the child. She was confined to the house three months, and was much debilitated.

The child died at the age of two and one half years of brain disease. Three years later a second child was born, and two years afterward a third, both of whom succumbed in early infancy to cerebral affections. She also had repeated miscarriages.

During the eight and a half years of married life she fell from one hundred and forty to one hundred and eight pounds in weight, and was extremely nervous, at times hysterical. She suffered at rare intervals with pain resembling gastralgia. Afterward she suffered occasionally from epigastric pain (sometimes connected with her monthly flow, but not invariably) up to January, 1871, when, suddenly, at the age of thirty-three, menstruation, which had previously been regular in every way, ceased, and there appeared in its stead severe attacks of pain in the neighborhood of the stomach, accompanied by epistaxis. These attacks were preceded for thirty to sixty minutes by a disagreeable sensation in the epigastrium, accompanied by depression and dread of suffering. The stomach seemed to be bloated, and the extremities chilled. The first impulse was to lie down and to double up until vomiting gave a little relief. The vomiting, which at the outset was never bilious in character (although when protracted it became so), was accompanied by moderate epistaxis.

For many years the attacks when promptly treated by morphine quickly subsided. In from two to twenty-four hours the stomach seemed fully restored to its normal condition, and our patient was again able to resume her duties. She had charge of a large boarding-house, and had a great amount of responsibility and care.

Mrs. H. was under the care of my father and myself during the greater portion of the last thirteen years. At no time were there symptoms of uterine disease or of peritonitis during this period. The pain resembled that of the passage of gall-stones, but frequent examination of the discharges showed the absence of calculi. Once during this period Mrs. H. was free from pain seven consecutive months, but, as a rule, suffered monthly. Of late years the attacks became more severe, and were of longer duration, but she always made a good recovery.

October 31st last she suffered from an unusually severe attack, which was followed by an irregular febrile attack, confining her to the house until November 20th. She could not be influenced by counsel as soon as the acute symptoms passed. Therefore I was not surprised to learn that on the 24th she was out-of-doors in the forenoon driving her horse, and in the afternoon was down town shopping. On this latter occasion a sudden and copious hæmatemesis came on, which came near proving fatal. She rallied, however, was kept very quiet, and was apparently steadily regaining health until the 7th instant, when dyspnœa was noticed. For several days she had complained of pain in the left side. Examination on the 7th showed a slight pleuritic effusion on the left side, which increased in amount up to the 9th, and came to a standstill. There was slight fever on the 7th, none on the 9th. Mrs. H. again seemed to be slowly rallying, and sedatives (which for a fortnight had been freely given) were now rarely required.

At three P. M. on the 11th instant she seemed to her friends to be in good spirits and very comfortable; she had just called for a book to read when she felt a sudden desire for an evacuation from the bowels, and fell to the floor. She passed blood, and vomited a few ounces of bright blood mixed with glairy mucus. Violent epigastric pain returned, and when I reached her, a few moments later, she begged frantically for ether. She was blanched, the pulse could hardly be felt, and I did not dare to give it to her. In fifteen minutes she ceased to breathe.

For many years we had been deceived by the magical recuperative powers of our patient, and had believed that organic disease did not exist, but had hoped (up to near the end of life) that the symptoms could be explained by periodical gastralgia. Repeated examinations during these years gave us no reason to suspect that the symptoms were due to aneurism.

Autopsy by Dr. E. G. Cutler eighteen hours after death.

There was about twelve ounces of fluid in the left pleural sac, of amber color, and containing several

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, December 13, 1882.

flakes of fibrine. The base of the left lung was adherent, the greater part of the lower lobe retracted and containing no air. At the apex the pleura was slightly thickened over a space the size of a silver quarter of a dollar. The right lung was free; at its base was a similar thickening of the pleura. The lungs were anæmic.

The heart was pale, firm, and of normal size; valves and muscle healthy. There was atheromatous degeneration of the aorta just above the aortic valves, and in patches along its entire course.

The stomach, liver, ascending, transverse, and descending colon and omentum were adherent to the anterior abdominal wall. The omentum was spread out, and attached in the pelvis to the broad ligaments on each side of the uterus. The stomach was distended by blood coagula and bloody fluid. The mucous membrane was covered by a dense layer of mucus. On the posterior wall at the cardiac end were two small perforations, with ragged, oval, shreddy edges, as large as a quill. These led into a large sac filled with soft clot, and with walls made up of spleen, diaphragm, stomach, liver, pancreas, and adhesions, and a portion of the wall of the splenic artery. On following up the arteries from the aorta it was found that the splenic artery had undergone aneurismal dilatation with rupture. The lower segment of the spleen was much softened, and appeared to be in a condition of anæmic necrosis.

The uterus was rather small; the Fallopian tubes were closed near the fimbriated extremity by the adhesions of the omentum spoken of above; there were old adhesions in Douglas' space.

The left ovary was greatly atrophied, and held in a dense cicatricial mass. The right ovary, the size of a large bean, on section was found to have a cyst occupying its entire bulk, filled with yellowish, apparently cheesy matter.

The other organs were simply anæmic.

RECENT PROGRESS IN FORENSIC MEDICINE.

BY F. W. DRAPER, M. D.

THE MEDICO-LEGAL RELATIONS OF RUPTURE OF THE SPLEEN.[1]

Dr. Pellereau, whose position as police surgeon and medical attendant at the prisons in the island of Mauritius enables him to speak with authority from his experience, states that in that tropical climate one of the most common causes of sudden death is the rupture of the spleen. Under the influence of malaria the organ takes on changes in its capsule and in its substance which favor this accident; its size is largely increased and its firmness is lessened, so that it is easily fractured. A table is given by the author which shows that of fifty-four cases of sudden and violent deaths occurring in two years and a half, and requiring his investigation, thirteen were caused by rupture of the spleen, nine being the result of blows or falls, and four having been of spontaneous origin.

The symptoms of rupture of the spleen, as observed by Dr. Pellereau, were those of collapse, more or less severe. There is pain, of a sharp and transitory character, referred to the left side; generally the patient falls with a cry, and presses his hand over the injured part. Hæmorrhage is the immediate cause of death, and the symptoms and suddenness of the fatal result depend largely on this hæmorrhage, its amount, and its source, and this in turn on the extent and situation of the rupture. Most of the symptoms, especially those which follow the initial shock, are attributable to the loss of blood. The post-mortem appearances, too, are largely the familiar ones of anæmia. The lesions found in the spleen vary greatly in depth and shape, as well as in situation and number. Sometimes they are longitudinal, at other times circular; they may be triangular or stellate; their borders may be smooth, as if cut with a knife, or they may be irregular and indented.

The author concludes his observations with answers to probable medico-legal questions that may arise in connection with rupture of the spleen. He declares that in tropical countries the organ being hypertrophied and softened its rupture is easy, the slightest violence being sufficient to produce that result; in other countries, where malaria is uncommon, the injury requires a considerable degree of force. Under favorable conditions in the organ itself the spleen may be ruptured by *contre-coup*. There is no way of distinguishing traumatic from spontaneous ruptures except by the presence of external lesions, and these are exceptional. The spleen may be broken by a blow or a fall without any contusion or external indication of violence whatever. A man can go about or continue his work, indeed, after his spleen has been ruptured; he may live for days, long enough for a secondary peritonitis to be developed, but generally death follows in a few minutes, or hours at the most.

ON RAPE DURING HYPNOTIC SLEEP.[2]

In the winter of 1880–81 a "magnetizer" visited Neuchâtel, and by his public exhibitions of his powers created a "magnetic" epidemic, especially among the young people. One of the results of this excitement became the subject of a judicial investigation. A young woman applied, through her pastor, for accommodations at a lying-in hospital for her approaching confinement. She declared that she was eight months pregnant, and that her pregnancy dated from one evening when she was alone with a young man who had the power of "magnetizing" her, and who had violated her after he had put her to sleep. The case came to the notice of the district officers of justice, and Dr. Ladame was required to answer, as an expert, the following questions: —

(1.) Is the statement of Maria F. to be regarded as trustworthy in its general features?

(2.) Did the sexual connection take place under the conditions described by her and without her ability to account for it?

(3.) Was her will wholly paralyzed, and could she not have resisted her seducer?

(4.) Is conception possible when the woman is in a state of absolute insensibility?

Dr. Ladame, in his reply to these judicial inquiries, first calls attention to the novelty of the subject in its medico-legal relations. He states that only four authentic cases of the kind in question are on record in medical literature. Liman, professor of legal medicine at Berlin, declares that in his experience of twenty

[1] Annales d'Hygiene et de Médicine Légale, March, 1882, page 223.

[2] Annales d'Hygiene et de Médicine Légale, June, 1882, page 518.

years as a medical jurist he has not seen a single instance of magnetic sleep, and that he has never been called upon to pronounce upon a criminal case relating to magnetism. Hofmann, of Vienna, likewise asserts that he does not know a single case recorded in German literature of rape during hypnotic sleep.

In France the first case published occurred in 1858. MM. Coste and Broquier, the experts in this case, summarized their conclusions as follows: "We think that it is possible that a young woman should be deflowered and impregnated against her will, her powers of volition being overcome at the time by magnetism." The experts in this affair remarked further that "if a young woman under the influence of magnetic sleep is insensible to all sorts of pain it seems reasonable to admit that she can undergo the act of sexual intercourse without any voluntary participation in it, without, indeed, any knowledge of it, and that consequently she could not forcibly resist it." Devergie agreed, in consultation, with these conclusions, although he called attention to the great ease with which magnetic sleep could be simulated under such circumstances. Tardieu gave a qualified assent to these opinions, but remarked particularly upon the possibility of deception.

In a second case (1865) the experts expressed themselves in nearly the same terms as did those in the affair just related. A third case was published by Tardieu in 1878,[1] and a fourth, and the latest on record (1879), was under the investigation of Brouardel, professor of legal medicine at Paris, who arrived at results very nearly like those in the preceding instances, namely, that a girl may be violated during magnetic sleep.

After a full and interesting discussion of the various topics relating to the case under his observation, — the phenomena of hypnotism, the degrees to which the will of the victim may be overcome, the possibility of sexual intercourse in this condition without the consent of the woman, the means of distinguishing genuine from fraudulent hypnotism, the possibility of conception when the woman is unconscious from any cause, the author formulates as follows his answers to the questions propounded to him: —

(1.) We are compelled to admit that Maria F. could be violated by Louis V. after being magnetized by him. In this state she could not resist the intercourse, and she has not preserved any remembrance of what transpired, or a confused recollection of a part only of the occurrence.

(2.) Conception has frequently followed rape, and the date of the confinement of this girl shows that the fecundation coincided with the time of the alleged rape.

(3.) In the absence of a medico-legal investigation immediately after the occurrences in which the two parties were involved on the occasion in question, it is impossible to affirm positively that the woman was really put to sleep by magnetic influence with criminal intent and ravished while in that condition.

(4.) It would doubtless be easy to obtain a detailed account of that scene by magnetizing Maria F., but the experiment might be exposed to error, because in hypnotic sleep one can voluntarily or involuntarily suggest to the person sleeping dreams and hallucinations of which she describes the details with astonishing precision.

[1] Étude medico-légale sur les Attentats aux Mœurs, page 9.

(5.) Although important information might be gained by this renewed magnetizing of the woman, it would not in any case serve as sufficient evidence upon which to base a judicial conclusion.

MENINGEAL HÆMORRHAGE.[2]

Inter-arachnoid effusions have a very important medico-legal bearing, for the surgeon may be called upon to express an opinion whether the hæmorrhage is the result of violence, and the life of an accused person may largely depend on the surgical evidence. In doubtful cases two questions may be raised in defense of a person accused of murdering the subject of such a hæmorrhage: (1) was not the hæmorrhage the result of a diseased state of the blood or tissues of the deceased, or of over-excitement; (2) if disease or excitement was not the immediate cause of the hæmorrhage, was it not a strong predisposing cause, and would the same amount of violence have excited fatal hæmorrhage in a perfectly healthy person?

Mr. Morris summarizes his conclusions on the subject of meningeal hæmorrhage as follows: —

(1.) Spontaneous effusions into the cavity of the arachnoid, that is to say, effusions of blood from disease or excitement, are very often not to be distinguished from traumatic effusions.

(2.) Post-mortem examination does not always explain the cause or the source of the effusion, and the state of the blood-clot is only a very rough test of the age of the effusion.

(3.) Extravasation of blood between the dura mater and the bones, as also extravasations beneath the visceral arachnoid, accompanied by brain-bruising, are almost certainly traumatic, whether fracture coexist or not. Extravasations into the substance of the brain and into the ventricles are almost certainly spontaneous when no fracture and no brain-bruising coexists, and are probably so even when fracture without bruising of the cerebral surface is found.

(4.) Spontaneous effusions may occur without any naked-eye evidence of disease of the cerebral or meningeal vessels.

(5.) Spontaneous effusions into the arachnoid cavity from disease or excitement have occurred as early as the twelfth year of life, and at all ages subsequent to puberty. Inter-arachnoid hæmorrhage occurs at any age from violence.

(6.) In slight injuries of the head, such as small scalp-wounds, without fracture of the skull or bruising of the surface of the brain, the surgeon should be extremely cautious in attributing inter-arachnoid extravasation to a blow, and more especially when the injured person is of intemperate habits.

ON DEATH BY DROWNING.[3]

The frequency with which cases of drowning occur in the practice of medical jurists renders it of importance, from time to time, to pass under review in the light of experience the various post-mortem signs which indicate this form of death. This paper of Dr. Ogston has, as its basis, one hundred and seventy cases, in one hundred and thirty of which the bodies were

[2] Clinical Lecture on Hæmorrhage into the Cavity of the Arachnoid, its Surgical and Medico-Legal Aspects. By Henry Morris, M. A., F. R. C. S. Lancet, November 11, 1882.

[3] A Critical Review of the Post-Mortem Signs of Drowning. By Francis Ogston, Jr., M. D., Assistant to the Professor of Medical Jurisprudence in the University of Aberdeen. Edinburgh Medical Journal, April, 1882, page 865.

examined internally as well as inspected externally. Cases have been omitted from the review which from advanced decomposition or other causes did not show well-marked signs of death by drowning, or which presented other fatal injuries.

Of the external signs Dr. Ogston regards (1) the flowing of water, generally in abundance, from the mouth on turning the body, and (2) the presence of froth at the lips and nostrils, as the only ones which we can utilize as trustworthy indications of drowning. Other appearances on external inspection of the bodies of the drowned serve simply to strengthen these when they are present, and by themselves considered are individually of little value.

The following table gives the relative frequency with which these external appearances, both special and auxiliary, were found in the one hundred and seventy cases observed: —

EXTERNAL SIGNS OF DROWNING IN 170 CASES.

	Number of times observed.	Ratio per cent.
SPECIAL APPEARANCES.		
Water, sometimes frothy, flowing from the mouth on turning the body	24	14.1
White froth at the lips	34	20.0
White froth at the nostrils	22	12.9
Red froth at the lips	7	4.1
Red froth at the nostrils	14	8.2
AUXILIARY APPEARANCES.		
Bleaching of the hands and feet	141	82.9
Bleaching of the knees and elbows	45	26.4
Cholera hand	12	7.0
Pallor of surface of the body	67	39.4
Rosy patches on skin	90	52.9
Cutis anserina	106	62.3
Sand under the nails	5	2.9
Protrusion of the tongue	29	17.0
Erection of the penis [1]	13	16.6
Semi-erection of the penis [1]	42	58.3
Retraction of the penis [1]	17	23.6

[1] In 72 cases noted.

In studying the internal signs of drowning, while trusting again to the presence of water and froth in the body as the chief indication, we are assisted by the occasional presence in the respiratory tract of foreign substances, such as sand, sea-weed, and the like, by the fluidity of the blood, and by the usual signs of asphyxia. We have to look primarily for water in the air-passages; secondarily, in those cavities bordering on the lungs, especially when the body has lain in water some time; and, thirdly, in the digestive tract or its surrounding cavities. From the presence of white watery froth in abundance in the bronchi and trachea, and in a less degree in the œsophagus and stomach, we derive much trustworthy information, second only to that conveyed by the presence of water in those situations. That it is a watery froth, and not a mucous froth, as it is often erroneously described, may be shown by taking a little of it on the point of a knife and touching the bubbles with a needle, when they readily collapse, leaving only watery fluid; while if any trace of mucus were present it would then betray itself by the stringy residue that would be found along with the water.

To over-distention and perhaps rupture of the superficial air-cells of the lungs has been assigned a certain value; but apart from the more important œdema they have slight significance. The same remark is made by the author concerning the bulkiness and protrusion of the lungs which are observed on removing the sternum; when the lungs protruded in the author's cases water or watery fluid, often in great quantity, was found in the pleural cavities, and the protrusion was caused by the buoyant organs floating on its surface when the controlling pressure of the sternum was removed. [We cannot accept this explanation as true. — REP.]

While, in the majority of instances, the signs of asphyxia have been assumed to be the most striking appearances of the drowned, those of syncope were not of very rare occurrence in the cases observed by the author, while those of coma were seen more often than writers have generally conceded.

INTERNAL SIGNS OF DROWNING IN 130 CASES.

	Number of times observed.	Ratio per cent.
SPECIAL APPEARANCES.		
Water in the air-passages	85	65.3
Water in the minute bronchi and air-cells	101	77.6
Water in the œsophagus	19	14.6
Water in the stomach	97	74.6
Water in the pleural cavities	63	48.0
Water in the pericardium	22	16.9
Water in the peritoneal cavity	16	12.3
White watery froth in the mouth	24	18.4
White watery froth in the air-passages	87	66.9
White watery froth in the stomach	4	3.0
White watery froth in the pleural cavities	5	3.8
Sand in the air-passages	10	7.6
Sand in the œsophagus	1	0.7
Sand in the stomach	2	1.6
Sea-weed in the larynx	1	0.7
Sea-weed in the mouth	1	0.7
Over-distention of superficial air-cells	10	7.6
Rupture of air-cells	6	4.6
Bulkiness of the lungs	48	31.6
Protrusion of the lungs	9	6.9
Entire fluidity of blood in the heart	72	55.3
Partially clotted blood in the heart	36	27.6
AUXILIARY APPEARANCES.		
Blood in greatest amount in right heart	103	79.2
Blood in equal amount in both sides	17	13.0
Congestion of lungs	106	81.5
Congestion of liver, spleen, and kidneys	107	82.3
Redness of the trachea	24	18.4
Redness of the œsophagus	7	5.3
Congestion of the brain and its vessels	72	55.3
Pallor of the brain	6	4.6
OCCASIONAL APPEARANCES.		
A layer of blood under the scalp	10	7.6
Punctiform ecchymoses under scalp	7	5.3
Punctiform ecchymoses of pulmonary pleura	9	6.9
Punctiform ecchymoses on surface of heart	3	2.3
Punctiform ecchymoses on surface of spleen	2	1.6
Punctiform ecchymoses on surface of kidneys	1	0.7

The conclusions derived by the author from these data are: —

(1.) When an external examination only is allowed, if an abundance of water pours from the mouth when the body is turned face downwards, and if white watery froth is found at the mouth and nostrils, or if it may be made to issue from them on compressing the chest, we may be justified in giving an opinion as to the probability of drowning, especially when the accessory signs (rosy redness of the face and front of the chest, goose-skin, and bleaching and corrugation of the hands) are well marked; presuming always that no lethal injuries are seen on the body which would appear to have been inflicted before death, and no trace of corrosive action, etc., of poisons are observable about the lips, hands, or clothes; but, to justify one in giving a more positive opinion, he should have a detailed description of the locality in which, and the circumstances under which, the body was observed before it was removed to the place of its examination.

(2.) If a complete inspection of the body is permitted, we may give a more positive opinion when, in addition to the external appearances, we find water in marked quantity mixed with white watery froth in the lungs and stomach, and also, perhaps, a large quantity of watery fluid in the pleural cavities; when we find sand, sea-weed, and the like in the bronchi or trachea; when the lungs are bulky or protrude on removal of the sternum; and when the blood within the heart is wholly fluid, and, with these signs, there are marked appearances of asphyxia in the heart, lungs, liver, and brain.

ON LESIONS OF THE NECK IN HANGING.

Two contributions on this subject have appeared recently: one by Dr. Lesser, of Berlin,[1] the other by Professor Hofmann, of Vienna.[2]

Lesser notes the frequency of lesions of various parts of the neck in suicidal hanging. He has made a detailed table of the results of his autopsies upon fifty subjects, and it appears that in thirty-six of these he found other characteristic appearances than the groove produced by the cord; he mentions extravasations of blood in the soft parts, rupture of the inner coat of the carotids, fractures of the hyoid bone and of the larynx and ruptures of the cervical muscles. This latter injury was met with in eleven cases; the sterno-mastoid was the muscle chiefly involved; its rupture was never complete, and there was no hæmorrhage from its divided fibres. This absence of hæmorrhage, constant in the muscular ruptures, was frequently noted also in connection with fracture of the hyoid bone and of the larynx, and Lesser attributes it to compression of the wounded parts, his idea being that though the small vessels are divided they are closed by the pressure of the cord, and when the compression is discontinued by the removal of the cord after death the cessation of the circulation prevents any effusion of blood. In support of this theory two cases are cited in which, the cord having been loosened before the death occurred, extravasations were observed in the skin and subcutaneous cellular tissue on a level with the groove.

Hofmann confirms the frequency of the lesions which are described by Lesser, and which have not been mentioned by the majority of the classical authors. They have often been overlooked, precisely because they were not accompanied by any sanguineous effusion in the tissues of the neck. But Hofmann does not accept the explanation which Lesser gives of the absence of extravasations; he remarks that laceration of the vessels of the skin is difficult to admit on theoretical grounds when one remembers how often the integument remains unbroken after injuries which have seriously impaired the integrity of the subjacent parts. Lesser's observation that extravasations occur along the groove of the cord when the cord has been removed after the suspension and before the death has not been confirmed in a series of ten cases of suicide under these conditions in Hofmann's experience. With regard to other lesions in the deeper parts, Hofmann remarks that many of the fractures of the cornua of the hyoid bone and of the thyroid cartilage are produced indirectly by the tension of cord on the thyro-hyoid membrane, and he considers that these fractures are made during life and not by prolonged suspension after death has occurred. The absence of extravasations is explained by interruption of the circulation through pressure and complete obstruction of the carotids and jugulars by the cord. As the cord is usually found around the neck below the bifurcation of the carotids, the superior thyroid artery and vein do not permit any blood to pass through them; and the superior laryngeal and the hyoid branch of the lingual are often directly compressed.

In this connection mention may be made of some observations presented by Dr. Græme Hammond before the New York Medico-Legal Society.[3] After a review of various authorities on the subject of hanging and its attendant phenomena, Dr. Hammond described some original experiments undertaken to demonstrate the painlessness of death by suspension. With the assistance of two medical friends he submitted to the process of partial strangling in the following manner: While he sat in a chair a towel was passed around his neck, and the ends were twisted so as to produce forcible compression. One of the attendants attended to the towel while the other stood in front of the subject to watch his face and to make the necessary tests of the cessation of sensibility.

Dr. Hammond thus relates his experience: "I first noticed a sensation of warmth and tingling, beginning in the feet and quickly passing over the entire body; vision partially disappeared, but there was no appearance of any colored lights. My head felt as if about to burst, and there was a confused roaring in the ears, such as is heard when the ear is placed against the opening of a shell. I suffered no loss of consciousness, and was fully able to tell my friend whether I felt any pain from the knife-thrusts he was inflicting upon my hand. In one minute and twenty seconds from the commencement of the operation all sensibility was abolished. After a few minutes' rest a second trial was made in the same manner as before. This was followed by symptoms similar in character to those mentioned in the first attempt, except that sensibility ceased in fifty-five seconds. A stab with a knife sufficiently deep to draw blood was indicative of no sensation whatever."

From these observations on his own person, and from the writings of various authors, Dr. Hammond draws the conclusion that the "proper and orderly way to execute the law in the case of a person condemned to death by hanging is not to let him fall or to jerk him into the air, but to stand him on the ground or on a suitable platform and to adjust the noose carefully around the neck below the larynx; then he should be raised from the place where he is standing by pulling on the rope, which should pass over a pulley fixed to a beam above, and he should be allowed to hang thirty minutes. The rope should be soft and flexible (of cotton or flax), so as to fit closely to the neck. Carried out in this manner, an execution by hanging would be effectually and mercifully performed. The condemned man would undergo no physical or mental suffering from the moment the suspension began, and his life would be taken as speedily and with as much freedom from horrible events as the circumstances of the case would allow."

Of these things we may be positively sure, says the writer: that from the instant suspension takes place there is no sensibility to pain, and that the convulsions which ensue are no more evidence of pain than are the

movements of a decapitated chicken; they are such as always ensue with insensibility when the blood-vessels of the neck and the trachea are suddenly closed.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M. D., SECRETARY.

DECEMBER 13, 1882. Meeting called to order at eight o'clock by DR. GEORGE B. SHATTUCK, chairman.

DR. MORTON PRINCE read a paper entitled

THE TYPHOID EPIDEMICS OF THE LAST DECADE, AND THE NECESSITY OF COMPULSORY DISINFECTION,

which will be published in the JOURNAL.

At the conclusion of the paper, DR. H. I. BOWDITCH said that such a vigorous and outspoken plea for sanitary education and sanitary reform led him to feel new courage, and inspired fresh hopes. The able arguments presented, and the strong array of facts which were produced, should force conviction upon every listener, and be followed by a better appreciation of the value of sanitary work, and the necessity of strengthening the hands of those, who are striving to diffuse intelligence upon this momentous subject. The legislature should be petitioned to amend and enact laws which shall enable the health officers of the State, in both central and local boards to more fully and perfectly carry out the work of sanitary reform. Dr. Bowditch remarked that he was, at one time, connected with the State Board of Health, which endeavored to do good work in educating the people to an appreciation of the extreme dangers of filth pollution, and to other hygienic necessities. The action of the State authorities made it necessary for him to resign that position. At present, the State Board is powerless to carry on any sanitary work, and is burdened with other duties of a different nature. Boards of Health should be entirely independent of any other relation, and should devote their sole energies to the sanitary protection of the citizens; aided by such laws as may be required for the proper performance of this duty.

MR. ERNEST W. BOWDITCH said that he was very much interested in the paper, particularly in those portions relating to the diffusion of the typhoid infection by means of drinking water. Chicago has adopted the dangerous experiment of pouring its sewage into Lake Michigan, near the shore of the lake, and drawing its supply of drinking water from the same source, at a point only a few hundred feet distant. There would seem to be a constant danger to the health of the inhabitants from this cause, and an epidemic might break out at any time.

DR. E. A. W. HARLOW asked the distance to which surface pollution might extend so as to manifest itself by contamination of well supplies.

DR. PRINCE replied that this depends upon a variety of circumstances, such as character of soil, inclination of the surface or of the stratification of the soil, the nature of the subsoil, and the amount and character of the polluting material. Direct contamination of well water has been proved in distances of sixty to one hundred feet. One case is reported in which the poison traveled many hundred feet in a valley and contaminated the water of wells at a lower level. The epidemic at Lausen was very peculiar in this way. Here the infection passed under a mountain and appeared in the water supplying the village upon the other side. This fact was established by impregnating the water of the brook with coloring matter, which reappeared in the water issuing from the other side of the mountain, as well as by dissolving certain chemical substances in the brook, which were detected in the water supply of the village. This constitutes, perhaps, the most interesting and striking source of typhoid infection which has thus far been recorded.

DR. MARCY thought that this paper struck not only at the source and prevention of typhoid fever but of all germ diseases. We are now rewriting all our books in consequence of the knowledge which has been gained in the domain of infectious diseases, and the former limits of this class of diseases have been vastly enlarged, and may in the future be made to include many diseases not now supposed to be due to germ infection. As an example of this he mentioned a house in Blandford, Mass., situated at the foot of a decline of about twenty degrees, from a cemetery which was one fourth of a mile distant. This house has its water supply from a well, and has been the scene of repeated ravages of severe typhoidal and other febrile diseases.

Some years since he examined the village of Littleton, Mass., where an epidemic of typhoid had prevailed. The soil is a clayey loam with substratum, perhaps twenty feet below the surface, of clay. Surface drainage infiltrates to this almost impervious strata into which the wells for the household supply of water are sunk. There are on one street twenty houses which have been visited by typhoid fever, and the disease is constantly recurring. In every case where the disease had occurred, und indeed common to the whole town, the privy and the well were in close proximity to each other. In the present state of knowledge upon the subject of hygiene, we must believe that sanitary protection is necessary not only in typhoid fever, but in all diseases of an epidemic character. In twenty-eight States of our Union, laws have been passed looking to sanitary reforms and protective hygiene. In twenty-two States, laws calculated to regulate the practice of medicine have been passed. Massachusetts will certainly be recreant to her duty if she fails to keep fully abreast of the latest revelations of sanitary science, which must always constitute the most important protection to our people against the ravages of epidemic diseases. Physicians are at present more to be blamed than are the people, for the people depend upon the medical profession for instruction in matters of physical well being.

DR. J. H. MCCOLLOM. By far the greater number of cases of typhoid occurring in the city are those in which the disease has been acquired in the country, and is developed after returning to Boston. The disease is highly infectious, and is readily contracted in summer resorts, owing to the almost universal lack of sanitary knowledge, and the many conditions there present by which the poison may be disseminated among our peripatetic summer population.

The better class of patients are not only willing but are generally anxious to take every protective measure in typhoid fever, and disinfection of the discharges may be perfectly carried out in most cases. For this object a small quantity of sulphate of iron may be placed in the bed-pan, and after the dejection a small quantity of muriatic acid may be poured over the discharge, after

which hot water should be added before pouring into the water-closet.

DR. DURGIN said that typhoid should certainly be carefully disinfected, and at least half a dozen other diseases should be similarly treated. Physicians should realize more thoroughly than they do the grave necessity for these precautions, and then the public will soon learn to value the labors of sanitary reform. Boards of Health can accomplish but little without the coöperation of the medical profession. Over a year ago the origin of typhoid in Boston was made a subject of investigation by the Board of Health, and those investigations are still being carried on. Milk, water, and food, have all been subjected to examination as possible channels of infection, but as yet the results obtained are very meagre.

MR. PUTNAM asked if the ordinary water seal in traps is a sufficient protection against the infection of the air in dwellings from sewer gases. This question is one of great and increasing importance to architects and plumbers.

DR. PRINCE replied that recent experiments in Chicago show that a water seal may be traversed by gases without the aid of pressure. This was shown by means of a U-tube containing water. In one end of the tube was placed sulphuretted hydrogen gas, and in the other end were pieces of clean metallic lead. In a short time the surface of the lead was blackened by the action of the gas, which had passed through the water seal without the aid of pressure. Sterilized fluids were also infected by the passage of germs through the intervening water seal.

DR. G. B. SHATTUCK referred to the experiments and conclusions of Carmichael of Glasgow; his results indicate and support a different opinion.

In connection with the question of contagion DR. J. C. WARREN called attention to the work of French and German observers of the relations of bacteria to this disease.

Eberth has found a short bacillus in the mesenteric glands and spleen in a large number of cases of typhoid, and he noticed that the organisms in some cases were in an inverse proportion to the duration of the disease; but there were also a considerable number of cases in which he could find no organisms. Koch has found the same form of bacillus in all the internal organs in cases of typhoid; he has also seen other forms, namely, long bacilli and micrococci, but these latter he connects with sloughing ulcers of the intestine, finding them only in internal organs in the later stages of the disease. He does not yet feel authorized to speak definitely as to the pathogenic character of the short bacillus, as he also has failed to find it in about half the cases. Dr. Maragliano, of Genoa, has found organisms in the blood of typhoid patients during life. The blood was obtained by means of a hypodermic syringe, which was passed through the abdominal wall into the spleen. Blood was also taken from the tip of the finger with proper precautions. The examination of fifteen patients showed that at the height of the disease the blood of the general circulation contains micrococci and bacilli, the latter resembling both kinds mentioned above. During convalescence these organisms lessen in number, also when quinine was given in large doses they diminished greatly in number, or disappeared altogether. Both the long and short bacilli were obtained from this blood by the "fractional cultivation."

Dr. Warren reminded the members that there were other elements to be considered in the ætiology of typhoid beside that of contagion. The well-known tendency of the disease to reappear in waves of several years' duration, and then subside spontaneously, was familiar to hygienists. The State Board of Health of Connecticut had recently called attention to the subsidence of malaria in Connecticut and also in Massachusetts, where it had within a few years been reappearing coincidently with the return of typhoid.

Professor Ceri has come to the conclusion, as the result of his experiments with malarial germs and soils, that what he calls the *natural germs* of the soil are to be distinguished from the same variety when cultivated, which then have acquired a diminished power of resistance, both to the action of heat and quinine. These influences cause an arrest of the action of the germ without its destruction. The rise and fall of epidemics is said to be due to a gradual weakening of the organisms, caused by cultivation from individual to individual in the human system. The germs which have thus lost their infective power may, under favorable circumstances, regain that power by again becoming natural germs. Infected localities may become disinfected whenever favorable conditions, which are necessary to preserve the natural quality of the germ, cease to exist or are removed.

DR. MARCY alluded to the investigations of Sternberg, in which septic matter was introduced into the tissues of animals, and caused death by processes resembling in some cases the symptoms of typhoid.

DR. BOWDITCH spoke of the universal presence of bacteria in the mouths of healthy and cleanly persons. He showed these organisms to the late Professor Agassiz, who was disinclined to believe that they were ever to be found in the mouth unless there was disease present, until he discovered them in his own mouth. Only one case was examined in which they were not present, and in this case soap was used in cleansing the teeth after every meal. The patient was a young lady. Dr. Prince spoke of a virulent outbreak of typhoid from eating the flesh of an infected animal, which must therefore have been supposed to have been suffering from typhoid. This is a new and unexpected source of danger in this disease.

DR. MARCY mentioned the typhoid infection of drinking water from the bodies of those dead with this disease, by means of leaching from the cemetery to a well, which was located on a lower level, though some distance away. Thus it seems that the poison of typhoid is equally potent whether it be taken in bulk, with food, or in the form of a cold infusion, as instanced in the grave-yard pollution. The question at once arises as to what we shall do with the infected bodies of those dying with typhoid or other epidemic diseases, which seem to be able to affect the public health, even when buried in the earth. Here would seem to be a most important reason for advocating the cremation of the bodies of the dead, particularly in cases of infectious or epidemic diseases.

At this point DR. HAROLD WILLIAMS presented the following resolutions, which were unanimously adopted: —

Resolved: That in the opinion of this Society the history of the past ten years has shown that one great element in the causation and spread of typhoid fever lies in the diffusion of the poison by the intestinal discharges of persons sick with the fever; and this Society

recommends that these discharges be thoroughly disinfected in every case before being disposed of in the privies and sewers.

Resolved: That we, as members of this Society, pledge to the State Board of Health, Lunacy, and Charity, and to the Board of Health of this city, our moral support and hearty coöperation in carrying out whatever measures they may deem necessary for the prevention of typhoid fever and other contagious diseases.

Resolved: That as in the opinion of this Society the number of towns availing themselves of the present statute relating to the appointment of boards of health and health officers throughout the Commonwealth is much less than the public welfare demands, being much less than one half the whole number, this Society recommends to the Suffolk District Medical Society to memorialize the State Legislature for the enactment of such laws as are necessary for the prevention of disease, and to raise sanitary legislation to the present standard of sanitary science.

Resolved: That the secretary of this Section is hereby directed to present these resolutions to the Suffolk District Medical Society at its next meeting, with a request that a committee be appointed to take them into consideration.

MR. ERNEST W. BOWDITCH read a paper upon

THE SIPHONING OF SEWER TRAPS.

By means of a diagram it was shown that the ordinary form of trap which is supposed to form a protection against the entrance of sewer gas from the drains into dwellings is always unsafe, and often entirely useless. The most elaborate and best ventilated system of house fixtures do not in the least obviate or prevent this accident, so that it is liable to bring infection into the best built houses.

The cause of the unsafe condition of the sewer is the fact that the sole obstacle to the entrance of gas into the house fixtures usually consists of a so-called "running trap," which is supposed to effectually seal the pipe between the house and the main sewer or cesspool. The fact, however, is that the flow of water through the drain, particularly if a considerable quantity be discharged suddenly, tends to empty the trap by means of the suction produced by its passage through the farther portions of the drain, and thus an unobstructed channel is at once opened between the sewers and the dwellings connected with them. The proposed remedy is to place a ventilating tube in the drain, so adjusted as to communicate with the lowest part of the cavity of the trap, thus allowing gas within the drain to escape through this ventilator instead of backing up into the house system, and also allowing air to enter the drain when from any cause there may be suction toward the sewer, thus preserving the integrity of the seal between the house system and the sewer or cesspool.

DR. JAMES B. AYER presented a paper upon

DEATH FROM RUPTURE OF AN ANEURISM OF THE SPLENIC ARTERY.[1]

DR. E. G. CUTLER showed the organs exhibiting this interesting pathological condition, and described its more striking features.

Dr. Cutler also showed a peculiar concretion of a calcareous nature, which had been felt beneath the skin of the leg in a young lady, and which had recently been discharged by inflammation and ulceration. It was hard, of whitish color, and shaped much like the incisor tooth of a squirrel, except that it was thicker in proportion to its length.

In connection with the first specimen DR. PRINCE alluded to a case of aneurism of the cœliac axis, seen by him, in which the symptoms were very similar to those of the case reported in this paper.

DR. CUTLER said that he had previously made the autopsy of four similar cases.

The Section voted to present the volume of the Transactions of the Pathological Society of Philadelphia, lately received from that Society, to the Medical Library Association, where the former volumes of the Society's reports are already preserved.

Adjourned.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

JANUARY 22, 1883. DR. CHARLES D. HOMANS presided.

A CASE OF TUBAL PREGNANCY.

DR. GANNETT showed the uterus and ovaries from a case of tubal pregnancy. The woman had been married two years. Her pregnancy began in November, and she enjoyed good health for eight weeks. In the right ovary and Fallopian tube was a clot the size of the fist. She lived eight hours after rupture, there being a quart and a half of blood lost, but no fresh peritonitis. The marks of old peritonitis from a former miscarriage existed.

CALCULUS OF BLADDER.

DR. GAY showed a calculus from the bladder. A first operation by Dr. Bigelow in May gave complete relief for a time. It is a question if the whole stone had been removed then, as a small piece is harder than the rest and may have been a nucleus.

OSTITIS AND ARTHRITIS.

A discussion on Ostitis and Arthritis was opened by Dr. Fifield.

DR. FIFIELD meant to speak to-night of arthritis, not in connection with rheumatism or gout, but with diseased bone, and secondary to that.

Of ostitis, he preferred to consider it as inflammation or disease of bone as a whole rather than in detail, as of periosteum, bone, or of the medulla.

Leaving aside for the moment inflammations of bone as produced by syphilitic or malignant disease, he would allude to Monsieur Gosselin's useful and scientific division of the inflammatory lesions of bone into traumatic and spontaneous ostitis. The traumatic again to be subdivided, so far at least as regards the long bones of the skeleton, into those in which the bone has been struck by an object which does not destroy, or perhaps greatly injure, the soft parts overlying it, "ostéite traumatique abritée," and those where the bone is exposed by division of soft parts or by removal of them, "ostéite traumatique exposée." Both these divisions lead up to hypertrophy, atrophy, or even to suppuration.

As to the first division, the speaker drew attention to the callus succeeding to fractured long bones, always to be recognized for a very long time, perhaps for life, whilst in the young child it could totally disappear.

Again to neuralgic pains following hyperostosis of bone, as in callus, rebellious to remedies.

In regard to the second division, compound injuries of bone, "ostéite traumatique exposée," the fat of bone is said to play an important part in this form of injury as well as in those sheltered from the air, fat emboli of the lung occurring in the latter, the change claimed by Klose, of Breslau, 1856, to take place in the latter and in the conversion of the fat of bone (oleine) into a fatty acid, which, together with other matters, effused blood, pus, etc., forms a toxic compound producing septicæmia.

M. Gosselin claims that in 1859 he set forth the same idea in regard to compound fractures of the tibia as contributing to the gloomy prognosis in this injury.

The second division of ostitis as set forth by M. Gosselin, namely, spontaneous ostitis, resolves itself mainly into a consideration of what has been spoken of variously as diffuse phlegmonous periostitis, ostitis of adolescence, meaning by this a period from the commencement of the second dentition to perhaps the twentieth year, and exceptionally much further on (the ostitis of newly-born children to be considered apart), osteomyelitis, acute necrosis, etc. All these our best authorities would unite under one name, acute ostitis. This ostitis, so far as the speaker knew, did not lead to hypertrophy of bone, to deformity from such hypertrophy, or even to atrophy, but was, as a rule, with some exceptions to be presently mentioned, connected with suppurative abscess as the leading symptom. It is this subject that has engaged so many famous pens, Chassaignac, Demme, Schutzenbergen, Boeckel, Krug-Buse, Vormsen, Hedoin, Giraldes, Lonnet, Ange, Morse, Gosselin, Klose, Gamet, Sezany, Roser, etc., etc. All these have written in regard to abscess connected unmistakably with diseased bone, bone to be felt or seen, bone discharging splinters or bone dust, almost all, or all in fact, occurring near the epiphyses of the long bones, mostly at the lower end of the femur.

To these Dr. Fifield would add a form of abscess, found especially in the latter situation, which might with truth be classed as a supraperiosteal inflammation. It appears frequently without pain and without œdema, but fluctuates, and an incision lets out either laudable, well-concocted pus or a large quantity of blood with but little pus floating with it. The finger pushed to the bottom of the wound reaches truly to the bone, but from which a velvety structure separates it. It is scarcely ever seen excepting in young people. Dr. Fifield cited a case seen in his hospital service this autumn. He had never known such abscesses to be followed by necrosis.

The exceptions to ostitis of adolescence, accompanied by abscess, should here precede our consideration of the general truth and rule. Nearly all the writers heretofore mentioned refer as a cause for these cases to the existence of the epiphyses of the long bones (I include here what may be called the long short bones, such as the metacarpal, metatarsal, and phalangeal bones): these epiphyses, by reason of their great nutrition and rapid growth, and their often exposed situation, predisposing them to irritation and inflammation, whether from interior errors or from outward injuries. Some of the writers prefer not to limit their theories to conditions of the epiphyseal cartilages, but include a thin layer of spongy or cancellated bone lying between the epiphysis and the diaphysis, notably Gamet, These de Paris, 1862, Osteo-periostite juxta-epiphysaire, Osteo-periostite dia-epiphysaire, by Sales.

Now it would seem from the observations of clinicians, of whom perhaps M. Gosselin is as famous as any, that the epiphyseal cartilages are the seat of inflammation of various degrees, from irritation to the most destructive and rapid manifestations of phlegmonous processes; that the predisposition to irritation and inflammation of epiphyseal cartilages, and their severity, varies in accordance with the end of the bone involved; that as it is at the lower extremity of a long bone, generally speaking, that growth takes place most rapidly; it is here that more frequent and greater phenomena of disease may be witnessed. It is from a knowledge of these things that the man of the clinic draws inferences which lead him to correct judgments and truthful prognostications in regard to certain cases placed before him. Thus a youth coming with a shortened limb, a more or less flexed and stiff knee, hip, or elbow, concerning which he can give no more information than a history of fever, pain, and tenderness, a confinement to bed, or needing the assistance of a stick, may have all these things as the effect of an irritation or subacute inflammation of an epiphyseal cartilage, giving rise to what is known as a plastic arthritis, known in French parlance as "arthrite de voisinage." Perhaps not even this has been produced, but such an increase of size of condyles as has prevented normal flexion, and almost brought about a sub-luxation. Such cases Dr. Fifield thought he had seen. One was that of a young girl, who had a very considerable enlargement of the inner condyle of the left humerus, preventing flexion, and exactly simulating the deformity left after a fracture. The case was afterwards shown by the parents to many surgeons, being careful not to divulge to each successive one the opinion of his predecessor. Nearly all pronounced that a fracture had taken place, and some even advised a suit for malpractice. At last Dr. Cheever was consulted and arrived at the same opinion as the first surgeon who saw the case, namely, that it was one of overgrowth of the condyle. The girl was an only child, had been most carefully watched both in-doors and out. The parents had no knowledge of a fall, neither could the child recollect or admit ever having had one. A second case had been brought to Dr. Fifield from the South Shore; in this instance the increased growth had been at the lower end of the femur.

Of the effect of diseases of the bones and epiphyses on the growth of the former, some observations of M. Ollier may not be without interest:—

First. Ostitis has different results upon the growth of bone, according to the part affected.

Second. The arrest of development in cases of juxta-epiphyseal ostitis is observed when the inflammation is situated altogether on the boundary line of the cartilage of conjunction, and attacks this cartilage. In the case of a patient whose radius had ceased to grow since the age of eleven years, after an attack of acute ostitis, the hand was thrown outwards towards the radial side by an increase in growth of the ulna. Two years after the commencement of the disease the radius was three centimetres shorter than that on the other side of the body. To arrest the progress of deformity M. Ollier destroyed the cartilage of conjunction at the inferior extremity of the diaphysis of the ulna. It was followed by complete success.

Roser says that he has seen in the thigh elongations

of many centimetres. More than once he has seen the tibia become elongated, whilst the fibula remained stationary, which brought about a tibio-peroneal dislocation. The same author has seen the ulna cease to grow, with the consequence of a dislocation upwards and forwards. When, on the contrary, the radius has ceased to grow, the lower extremity of the ulna is dislocated, and the hand takes well-marked abduction. He has moreover seen a remarkable elongation of the articular ligaments in the neighborhood of ostitis; an abnormal mobility resulted from this, which the author compares to the articulations of "Punch." Roser claims to have established the following facts: —

First. That what he calls osteomyelitis can bring about a premature disappearance of bone between the diaphysis and the epiphysis. Thenceforward all development of bone ceases.

Second. That when the inflammation does not appear at the epiphysis, but only in its neighborhood, it produces an exaggerated proliferation of bone in this place, and thence an elongation. We are indebted to Dr. William Hunt, of Philadelphia, for a practical application of this subject of different lengths of limbs to the relief of distressed practitioners, haunted by fears of suits at law for damages.

Another form of irritation or inflammation of an epiphyseal cartilage is that described by M. Gosselin as the "ostéite trochanterienne apyrétique," characterized by pain on pressure over the process, and lameness, often obliging patients to keep their beds, or to walk with crutches, during a year or two. Mistaken occasionally for true hip disease, and treated as such, it is perfectly recovered from, and perhaps an undeserved credit is gained for a cure of real disease of the joint.

Still another consequence of disease of the epiphyses, not resulting in suppuration, is that described by Ollier through his pupil, Poncet, entitled albuminous osteoperiostitis, namely, a collection of liquid below the periosteum, and situated near the extremity of a long bone. The liquid is said to be viscous, albuminous, transparent, sometimes green, sometimes colored with blood, sometimes mixed with drops of oil. The treatment is said to be best conducted by repeated punctures with a trocar or aspirator, followed by compression. We have no accurate knowledge of the prognosis, probably from the paucity of cases well observed.

Dr. Fifield spoke from his own observation of a case of disease of the cartilage of conjugation of the upper part of the tibia followed by suppuration of a very mild type, but producing a partial separation of the diaphysis from the epiphysis. Such instances are common enough in the services of the large hospitals of Europe, and are accompanied by extrusions of slivers of bone from time to time, sometimes producing, particularly when occurring at the inferior extremity of the tibia, slow inflammations of the ankle-joint, recovered from at length if the surgeon refrain from operating. In the case seen by Dr. Fifield the diaphysis of the tibia could be bent to and fro from the epiphysis. Amputation was talked of but never performed, and now the doctor occasionally meets the middle-aged man returning from his chopping of wood and hoeing of corn with a very useful leg. Dr. Fifield has not been able to find a record of a similar case where disjunction had proceeded so far and was yet recovered from. This form of disease is undoubtedly seen in the humerus, clavicle, wrist, and other parts.

We name here from memory the disease described by Professor Parrot, physician to the Hôpital des Enfants Assistés, the curious cases of disjunction of epiphysis from diaphysis in the newly born, whose helplessness of limb is sometimes attributed to paralysis rather than to its right cause. It has been principally observed by Professor Parrot on the skeletons of children who have died of congenital syphilis.

We now come to the part of our subject not yet cleared from the confusion which has hung about it since Chassaignac first described it in 1853, and who has been followed by many writers, chief amongst whom are Giraldes, Klose, of Breslau, and Gosselin; the terrible disease known under the various names of subperiosteal abscess, osteomyelitis, acute periostitis, osteo-epiphyseal periostitis, diffuse phlegmonous periostitis, osteomyelitis, ostéo-periostite juxta-epiphysaire, pseudo-rheumatismal inflammation of the bones and articulations. It was to a form or variety of this disease that Chassaignac gave the name of typhus or typhoid of bone, from the prominence of the symptoms of these diseases masking the real one, giving rise not only to errors of diagnosis, but to those of treatment.

Gosselin gives the symptoms as acceleration of pulse, elevation of temperature, thirst, dry tongue, intense headache, stupid appearance of face, want of appetite, delirium. At the same time, or twenty-four or thirty-six hours afterwards, pain is complained of in the limb or limbs about to be diseased, then deep and diffused swelling. These symptoms endure for periods varying from four to fifteen days. The swelling spreads, becomes less hard, but the skin is not reddened, then fluctuation is recognized, at first with difficulty, sometimes confined to one side of a limb, and sometimes surrounding the whole of it. Death is the usual result with the symptoms of pyæmia, but it is said not to be accompanied by the presence of metastatic abscesses in other parts. Recovery is said to take place occasionally, and to be followed by immense necroses.

Klose, of Breslau, in 1858, wrote an article on this disease under the title of Separation of the Epiphyses. He claims to have witnessed the separation of the epiphyses at the lower end of the femur, and the extrusion of the blackened necrosed ends of the diaphysis.

This form of disease the speaker had never seen, deriving all his knowledge from books, unless the following case, seen at the hospital, might be such an one: —

A. S., aged twenty years, entered hospital October 27, 1882. Had been sick two weeks then. She ran on with all the evidences of typhoid fever. On November 7th, thirteen days after admission, she had a chill at night, temperature rising to 104° F. She complained of pain in knees and back. Two days later another chill at night. Nothing found by examination to account for pain in knees. (Attention is here called to the name pseudo-rheumatismal inflammation of bones and articulations given to this disease by Roser.) On the 23d of November, ten days after first chill, some induration was noted in left thigh. Poulticed. On the 30th thigh swollen and tender. December 3d. Fluctuation. Incision, and a basin full of very offensive pus was removed. Cavity washed out with carbolic solution and drained. Four days later a counter-opening was made on inside of thigh, and the bone found denuded as far as the finger could reach. Fearing bleeding from the wound she was transferred

from medical to surgical side of hospital. She came under charge of Dr. Fifield. At this time no elevation of temperature was observed. Pus rapidly formed in the right thigh; a large quantity was removed by aspiration, then abscess cavity opened by knife; bone found perfectly bare as far as could be reached. Death. It is much to be regretted that no autopsy could be had.

It seemed to the speaker that scarce a better picture could be drawn of the disease than the one here presented. Chassaignac paints his in still more lurid and baleful colors. Here is his description: Headache, want of sleep, delirium. Sleeplessness exists in all cases, with children as well as with adults. Delirium belongs to all, with this peculiarity, namely, that it exists only at night. Diarrhœa. Loss of appetite. Thirst. Involuntary evacuations. Diarrhœa has usually come on about the thirteenth day. Dry tongue. Fuliginous teeth. Sloughs over sacrum. Diphtheritic patches in the mouth. The pains in the limbs are said to be awful in their severity, patients screaming with terror at the approach of the least contact. Dreading the knife, they fear even more the necessity of moving away from it.

When the abscesses are opened the pus has been seen to contain oil globules. Roser believed this to show that the medulla was inflamed, and that the oily globules of it passed through the bone in consequence of arterial pressure, citing the fact, if it be one, that water poured into the holes made by a trephine, or those existing in connection with necrosed bone cloacæ, became agitated by pulsations synchronous with those of the heart. Roser was shown cases where, although the pus contained oil globules, the medullary cavity contained none. Yet he held this to be an additional confirmation of his position. The oily globules and pus had passed through so quickly that none had, very naturally, been found when the cavity was opened. His pupil, Dr. Andrea, is said to have performed a curious experiment in this regard. He plunged a fresh tibia into water at 30° Réaumur, that the fat might become fluid. This done, he opened the medullary canal by sawing off the superior part of the diaphysis. Then on the inferior part he removed the periosteum over an extent equal to a five franc piece. He afterwards fitted a stick to the cavity. If the stick was forced rapidly up and down, one saw the drops of fat issue rapidly from the Haversian canals. If it was played slowly, then the oil escaped drop by drop. Some of these ostites, having their origin in epiphyseal cartilages contained within joints, may be accompanied from the commencement with the purulent arthrites that Chassaignac has told us developed themselves in such an insidious manner, and with such slowness, in contrast with the other symptoms. We remember with pride that our dear and regretted friend, the late T. B. Curtis, whose knowledge was all-reaching, used to insist on this origin of many cases of hip disease contrary to the contusion theory put forth by a New York surgeon as accounting for all. Boekel has cited two cases in adolescents, double coxalgias, ending in some days in diarthrosis (meaning by this, perhaps, a separation of the head from the neck of the bone), and of which the course resembled completely that of phlegmonous periostitis.

The treatment of such cases as have been described under the name of typhoid of bone consists, by the almost unanimous consent of all surgeons, in the making of early and free incisions into the affected part. Spillman, of Strasburg, wishes them to be made as soon as pus is suspected, before fluctuation is to be perceived, declaring that even if pus is not reached the operation will prevent the plastic products from being transformed into purulent matters. Billroth, on the contrary, wishes that they may be postponed until fluctuation be evident and the skin thinned. Martin Smith, of America, desires that the surgeon trephine the bone, but is frowned upon by the majority of writers. The treatment of Demme should be noticed here on account of the very brilliant results claimed by him. Impressed with the idea of purulent absorption after incisions (most surgeons have the same idea) Demme empties the abscess sac by trocar, and only in the second period of the disease, that is, when the fever falls, makes his incision with a cautery of hatchet shape. He pretends, says M. Spillman, of the Val de Grace, to have obtained thirteen cures in seventeen cases.

It is a singular fact, still unexplained, that although we may have equally large effusions of pus, equally extensive denudations of bone, yet the fatal typhoid element is not present, and cases are recovered from although bearing with them indelible traces of the conflict. Such cases, perhaps, are those seen where a bone such as the humerus or tibia is attacked. The whole bone seems to die at once and to separate itself from one epiphysis or from both. Such a case was that of Edie G., City Hospital, service of Dr. Fifield, where the whole shaft of the tibia was exposed by an incision going from one end of the bone to the other, then the diaphysis divided in the middle by a chain-saw. The lower half lay perfectly loose from its epiphysis and was lifted out, the other half was divided at a short distance from the upper epiphysis and lifted easily out of its bed. A new shaft rapidly formed, and last winter the child was seen skating. Giraldes gives two or three instances of this kind. One was a removal and regeneration of the shaft of the humerus. Another case seen at the hospital in the service of Dr. Fifield was that of a young boy affected in a similar way as Edie G., namely, sudden death of the shaft of the tibia. Whilst waiting for operation the other tibia was found to be dead, almost before it could have been suspected to be diseased, then the right femur was found bare and lying in a pool of pus. Death quickly followed.

The fingers and toes also afforded instances of ostitis. Not only those seen in connection with whitlow, but where the trouble seems to have its origin in the epiphyseal cartilages. Dr. Fifield here cited a hospital case which seemed to be of such origin. The speaker also said that the subsequent behavior of bone bared by slough and suppuration of soft parts above it appeared to depend a great deal upon situation, for instance, in the fingers. When the last phalanx is bared it is inevitably dead, and is cast out or removed by the surgeon. Most generally the same is true of the middle phalanx, but in the first phalanx it not unfrequently happens that although the bone be seen by the eye and felt by the probe to be bare, yet the phalanx will heal with a depressed cicatrix without any exfoliation from the bone. It is believed by some writers that in these cases the periosteum is adherent to the overlying muscles and is lifted up with them by suppuration from the bone, sustaining no actual loss excepting over the spot where the bone is found bare. This may also occur in other situations than those spoken of.

A brief allusion was made to rheumatic ostitis, lead-

ing to hypertrophy and irregular growth of bone, and yet where no true articular rheumatism had ever existed.

Dr. Fifield also spoke of abscess of bone, and said that the symptoms as given by Brodie were not always to be depended upon as pointing to pus in a cavity of bone. One had such wearing, constant pain, aggravated at night, in hypertrophy of bone merely, the bone being more solid than natural. Another might present a cavity without pus. Another would present the same evidences without any recognizable disease at all. The finding of pus was a mere piece of luck, one guessed at it but never diagnosticated it.

DR. CHEEVER referred to one or two cases illustrating some of Dr. Fifield's points. It has been said that disease of shaft and of the joint are different in adults. This is not always the case. A patient, otherwise in robust health, had pain in the shaft of the tibia. The periosteum was incised with partial relief only, and then the bone was trephined. Eight or nine years after this patient had the identical condition near the inner malleolus. Again he got temporary relief from incision, and he was again trephined with relief. This time, however, he did not recover. There were hectic, etc., and he was amputated above the knee, making a good recovery. Dissection showed an unusual course of disease. Disease of the shaft and of the epiphyses are not commonly found together. He also referred to a case where nodules as large as a lemon seed existed near the root of the thumb-nail, not extending through the skin. He cut them out rather than to amputate. The patient slowly healed, and went away, but some time after, while shaking a horse by the bridle, he hit his thumb, with the immediate result of ostitis of the thumb. This was a mixed case, cartilaginous, not enchondroma, but ostitis.

DR. WARREN spoke of Dr. Fifield's remarks on typhus in connection with the bacterial origin of disease, and contrasted the views of the older French surgeons on spontaneous pyæmia with those of the modern pathologists. He thinks it important for surgeons to recognize that bare bone in the fingers, as spoken of by Dr. Fifield, does not always mean loss of bone.

DR. CHEEVER, while feeling a reluctance in cutting into bone and letting out pus, but also getting venous hæmorrhage, believes that incisions generally do best. We do get septicæmia and death without any break of surface. He referred to a hospital case of fracture of the leg with unbroken skin, but in which the patient died, having had chills and other septic symptoms.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

C. M. JONES, SECRETARY.

DECEMBER 4, 1882. DR. H. W. WILLIAMS presided.

DR. C. H. WILLIAMS read the regular paper on the

TREATMENT OF DISEASES OF THE LACHRYMAL CANAL,

in which the use of probes of not more than two mm. in diameter was recommended, also injections and collyria of weak astringents, and in cases of purulent dacryo-cystitis the injection of iodoform, this being held in suspension in an equal weight of water long enough to be drawn up by the syringe and injected through the divided punctums.

The average of measurements of the bony lachrymal canal in two hundred skulls gave 4.75 mm. as the mean, the largest being 6.5 mm., and the smallest 3.25 mm.

Although the bony canal in most cases is large enough to take probes of four mm. in diameter, yet the soft parts fill up so much of the space, especially in inflammatory states, that the large probes could only be passed with considerable danger of injury.

DR. WADSWORTH said the subject had been very well presented by the reader, and he had little to add. The affection was certainly often a very obstinate one, and apparently little influenced by treatment; now and then patients got on very comfortably by the aid of one or two probings at an interval of months or years. On the other hand, cases of acute phlegmonous inflammation of the sac — those only, however, that begin in this way, for, as a rule, phlegmonous inflammation of the sac is preceded for some time by overflow of tears, showing obstruction of the canal — frequently recover very readily after the abscess is opened without any or with but little probing.

He agreed with the reader that in general it is better not to employ the hollow probe with Anel's syringe. But in some cases the hollow probe is of value, and he instanced a case in which the ordinary probe seemed to pass freely through the whole length of the canal, while the use of the hollow probe showed that there was a firm obstruction, probably bony, occluding its lower end.

Styles seem usually to do much more harm than good; still, patients are occasionally seen who assert they have been permanently relieved of their trouble after wearing a style for a year or two.

Dr. Wadsworth also referred to a case of sarcoma of the posterior nares, which had forced its way through the lachrymal bone and simulated a dilatation of the lachrymal sac, and to two cases of double lachrymal abscess occurring in children during convalescence from scarlet fever.

In reply to a question by Dr. J. B. Ayer, DR. WILLIAMS said that fluids of the affected sac, especially if purulent, were very irritating, and the patient should be directed to keep the fluids thoroughly pressed out one way or the other, though it is preferable, when possible, to force them down through the nostrils. As regards bony obstruction, out of more than two hundred skulls examined he had found only one case of bony exostosis, and in this the canal was entirely closed. The section of the canaliculus is generally ovoid rather than round.

DR. WADSWORTH said that in a skull in his possession the long diameter of the canaliculus was twice as great as the short diameter. He agreed with Dr. Williams in regard to the importance of keeping the sac empty, but patients should be cautioned not to use much force, otherwise the sac wall may be ruptured.

In answer to a question by Dr. Post, DR. WILLIAMS stated that absorption of the affected tissue does not take place under the treatment by probes. The passage is merely kept dilated for the time until the irritating cause is removed, and the parts enabled thereby to resume their normal functions. He further stated, in reply to Dr. Parks, that Bowman's probes have no definite scale of accurate measurements; No. 6 would correspond to nearly two mm. of Theobalt's probes.

DR. CABOT showed an instrument of his own contrivance, which combined an exploring needle with a director.

Recent Literature.

Studies in Pathological Anatomy. By FRANCIS DELAFIELD, M. D. Vol. I. Plates i.–xciii. New York: Wm. Wood, 1882.

This is the first completed volume of a series of publications originally issued in monthly parts.

As the title indicates, it is not a systematic treatise, but a collection of studies upon special subjects. The author states in the preface that he "has attempted to follow the purely objective method, to see and describe whatever could be made out in the different post-mortem lesions of disease. Such a plan involves following Nature wherever she may lead, and gives rise to apparent contradictions which cannot be reconciled."

For the general reader such a plan is certainly not advantageous, and the usefulness of the book is restricted to the comparatively small number of specialists, who can put their own interpretation upon the facts presented by the author, and can control his errors of observation by their own experience.

Profuse illustration is the necessary accompaniment of such a work, and that this has not been spared the ninety-three plates interspersed among one hundred and thirteen pages of text bear evidence. Nothing has appeared on this side of the Atlantic with so many and such handsome original plates.

The large size of the plates, however, adds nothing to their value for the individual reader, and at the same time they are not large enough to be seen at any great distance. No additional details are brought out by amplifying to 750 and 1500 diameters over what could have been obtained by using 400 to 500 diameters. For instance, no further information is gained as to the intimate structure of the giant cell depicted in Plate 48, than if it had been seen at one third of that size.

The subjects treated in this volume are the connective tissue, the pleura, the peritonæum, pneumonia, acute miliary tuberculosis, chronic pneumonia, phthisis, and acute phthisis.

It would lead too far to take up each of these in detail. In all there appears a mixture of the ideas of the older pathologists with those of the more modern schools, and the distinction of some of the subdivisions which has been made appears to be one rather of degree than of kind, and to depend more on clinical than anatomical grounds. For instance, the distinction between chronic pleurisy and the chronic pleurisy of phthisis rests essentially upon the way in which the fibrine and organized tissue are arranged relatively to each other, and which is hardly to be regarded as a constant characteristic.

Not much has been added to the general knowledge of the subject from the study of pneumonia, and phthisis and tuberculosis are at best a tangled skein.

The beauty of the letter-press and plates are certainly to be praised, but this character seems rather to add to the cost of the book than to its value.

Transactions of the Medical Association of the State of Missouri at its Twenty-fifth Annual Session, held at Hannibal, Mo., May 16–18, 1882. 220 pages.

This volume contains a series of papers of average interest and merit. The address of the president on Quacks and Quackery in Missouri is of considerable length, and is startling in its revelations of the ignorance and immorality of a large number of so-called physicians in that State, and of the very considerable loss of life that is to be traced to their malpractice throughout that quack-ridden State. It is to be hoped that the Association may be successful in its efforts to secure legislation which may put an end to such a disgraceful state of affairs.

Pathological Anatomy, Pathology, and Physical Diagnosis. A Series of Clinical Reports Comprising the Principal Diseases of the Human Body. By J. A. JEANCON, M. D. Cincinnati: Progress Publishing Company.

The prospectus is so worded that one expects to find new and original plates illustrating cases of the author. On opening the specimen number, one is surprised to find a very poorly executed reproduction of the plates, and a translation of the cases of the classical work of Cruveilhier. To this is added a few paragraphs on "The General Pathology of the Nervous Centre," taken apparently from Charcot and other French authors.

First Annual Report of the State Board of Health of the State of New Hampshire for the Fiscal Year ending April 30, 1882, with the Registration Report. 1881. 318 pages. Concord: State Printer. 1882.

This book contains not only the usual statistics of epidemic and other diseases, but a number of papers of more than average interest to readers outside the State of New Hampshire. Among these we may mention an article on Adulteration of Food, by Dr. E. J. Bartlett, associate professor of chemistry in Dartmouth College, and one on Water Pollution, Public and Private, by Dr. A. H. Crosby, of Concord. We notice incidentally that the entire expenses of the Board for the year amounted to only $1495.33, which was less than half the appropriation.

Early Aid in Injuries and Accidents. By DR. FRIEDRICH ESMARCH, Professor of Surgery at the University of Kiel, etc. Translated from the German by H. R. H. PRINCESS CHRISTIAN. Philadelphia: Henry C. Lea's Son & Co. 1883.

This little volume of so-called "Ambulance Lectures" is intended for the general public, but in no sense to take the place of a physician's services, merely to direct the right kind of aid before the doctor comes. The first lecture gives a brief outline of some anatomical points, having reference to common accidents. The subsequent ones treat of hæmorrhage, wounds, fractures, sprains, burns, drowning, poisoning, etc. The illustrious translator adds a preface to her country women, in which she says that the possibility of relieving suffering, and perhaps by timely assistance of even saving a life, should more than counterbalance the scruples that some might feel in entering on such a study. Of the soundness of the advice given for immediate treatment the name of the surgeon giving it is an abundant guarantee.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 15, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 Park Street, Boston, Mass.

THE MEETING OF THE NEW YORK STATE MEDICAL SOCIETY AND ITS CODE OF ETHICS.

The New York State Medical Society, at its recent meeting, confirmed its action of last year with regard to the rejection of the Code of Ethics of the American Medical Association, and by a decisive vote refused to change the Provisional Code which it then adopted; a code which, under the name of the New York Code, has been generally discussed by the medical press, and almost without exception adversely. It will be remembered that it copies very closely the former Code, except that it encourages freedom in consultations, and makes up for it by being very stringent with regard to advertising, which seems like excusing sins we are inclined to by condemning those we have no mind to. This Code is called a provisional code, because its chief advocates, those who exerted themselves so actively in having it adopted by the Society, have now openly abandoned it, and have introduced an amendment, to be acted upon at the next meeting of the Society, abolishing this Code and substituting simply the formula that the only offenses for which a member can be disciplined shall be comprised under the heading of "conduct unbecoming a physician and a gentleman." Inasmuch as the law does not require a physician to be a gentleman, and since the abolition of the National Code of Ethics was chiefly urged because it established a standard above that of the law, and was therefore illegal, we do not see how the authors of this simplified Code can consistently support even this; it would seem that there can be no safe ground for them to occupy short of the abolition of all codes, in cases of disagreement invoking the protection of the courts. To this at last must all medical societies come, which, abandoning their own legitimate field, — the cultivation of medical science, and the promoting of mutual acquaintance and good-fellowship in the profession, — assume to legislate for the government of physicians, and to adopt political methods in their management.

It is apparently an unfortunate circumstance for the New York Society that its annual meetings have been held in Albany at the time when the Legislature is in session; the air being full of politics, the miasm has apparently infected the Society, and its recent sessions show it to be deteriorating from a medical society proper into a medico-political society, imbued with an ambition of becoming the medical legislature for the Empire State. It is not without significance in this connection that a committee was appointed to secure a room in the new Capitol for the future meetings of the Society.

The fact that the majority of the medical profession in the State of New York and more than two thirds of the county societies have expressed their disapproval of its action upon the Code of 1882, without influencing the action of the State Society this year, appears to demonstrate that this Society has ceased to be a representative body, and now asserts its right to act as a legal board of control by authority vested in it by its charter from the State. Those most active in the movement which has crippled the usefulness, and threatens the existence, of the Association, are almost entirely from the eastern part of the State, and the county society most distinguished in its advocacy of the measures adopted was the Society of the city of New York, although it is true that a petition signed by some of the oldest and most prominent members of the Society was presented in opposition to its action. It is greatly to be regretted, for the sake of harmony and good feeling, and the best interests of the Society, that the temperate and conciliatory course advocated in this petition was not followed. It recommended rescinding the obnoxious amendment which deprived the Society of its representation in the American Medical Association, and urged the sending of delegates to the next meeting of the Association instructed to ask for such modifications of the Code of 1847 as would meet the views of the medical profession generally. But this suggestion was treated with open disrespect by the new Code advocates.

There is one fallacy that should be pointed out which underlies the entire discussion: it is that the law makes the physician, and that the physician is an officer of the law. If this is granted then the closer our State societies can nestle under the wings of our State legislatures the better, for only in this way is to be obtained the necessary power to govern such a large body of sanitary police as we find in the American medical profession. But this cannot be granted, because it is not true. A physician in this country is a private citizen; he is recognized by the law, and responsible to it like other citizens, but he is not made a physician by legal enactment, nor is he a State officer, and if he is wise he does not wish special legislation, for experience has shown that whenever the profession has tinkered with the law it has been made to suffer for it in the end. The lesson also is so obvious that he who runs may read, that the more our societies confine themselves to their proper field, — the joint cultivation of medical science and good fellowship, — and the less they meddle with medical politics, the better it will be for their own future and the common good of the profession. Although the question will be again brought up next year in the action upon the several amendments that have been referred, it is hoped that a better sentiment will prevail, and that some course may be determined upon that will harmonize the views of the members, and that will commend itself to the judgment of all. If

there is any delegate who persistently interrupts the scientific labors of the Society by engendering disputes and ill feeling and efforts to divide the Society into factions he should be summarily dealt with; if necessary expelled for being guilty of "conduct unbecoming a physician and a gentleman."

The late meeting of the New York Society shows the effects of these disputes, it being confessedly unusually devoid of medical or scientific interest. The papers themselves represented almost exclusively the specialists of New York, who seem to have had control of the meeting in all its aspects; they were not attentively listened to, and discussion was conspicuous by its absence. The net result is to impress the mind with a sense of the predominance of the commercial over the professional or scientific elements of the practice and pursuit of medicine.

THE HOUNSLOW SUICIDE.

IT is long since any event of a personal nature has excited the interest at once of the public and of the medical profession in England, which has been called forth by the Hounslow affair. As the lessons of this tragedy are the same for both sides of the Atlantic, we think it worth while to lay before our readers the main facts in the case.

Dr. Edwardes, a young man, aged thirty-two, who had achieved a good name in London, as a medical assistant, entered into practice about fourteen months ago in Hounslow, a suburb of London, whose name suggests Dick Turpin and such folk, where he had purchased for £1800 a half-interest in the business of Dr. Whitmarsh, an established practitioner. Dr. Edwardes was a married man, of good presence and affable manners, and soon made a favorable impression in the town. He found, however, that the pecuniary returns which had been promised him were not forthcoming, and, while doing most of the hard work, he was making but a bare living, while his partner, with an office practice, was taking the greater part of the profits. Dr. Edwardes had repeatedly expressed to his wife that he was not being properly treated, and had regretted that they had not chosen some other place to begin life, but neither of them had made any public complaints. Things went on thus till some two months ago, when the doctor was called to visit a pretty, young, married woman, who was suffering from some thoracic affection, for which he examined her with the stethoscope. Directly after she told one of her neighbors that the doctor had taken liberties with her, and made improper proposals. Of course, the story once started spread like a pestilence, reaching the ears of the victim last. He met it with a prompt denial. Mrs. Whitmarsh, with exemplary delicacy, brought the story to Mrs. Edwardes, who showed her the door. Dr. Whitmarsh had mean time privately visited the patient, and had spoken very disparagingly of his partner. He however visited her with Edwardes, at the latter's request, on which occasion the woman gave a written retractation of her charges. In spite of this Whitmarsh advised Edwardes to leave the town, which he, of course, refused to do. New stories were started, which Edwardes was taking legal measures to punish, when the woman brought a counter suit. At this point Edwardes found that his partner not only refused to stand by him, but actually proposed to enter the witness box against him unless he would give up his practice and go away. An agent of Whitmarsh came to Edwardes, overwhelmed as the latter was by his misfortunes, to demand an immediate answer as to whether he would accept a small sum and retire from the field. Edwardes promised his answer that night. It was given by prussic acid. The unfortunate man was found dead, leaving a letter in which he gave the story of his wrongs, and ended with the words, "*May God curse Michael Whitmarsh.*"

Then the fickle public, who had merely been indulging in the harmless amusement of talking scandal, found out what they had been doing, and their attempt at reparation took a form which our English friends would probably say was much more likely to occur in an American mining-camp than in a quiet English village. The mob stoned the house of Whitmarsh and leveled his surgery to the ground. He and his family fled the town. The body of the unfortunate Edwardes was buried with honors that rarely have been given to a confessed suicide. The coroner's inquest, which has been made the occasion of a searching investigation into the circumstances of the affair, resulted in a verdict that Dr. Edwardes had died from prussic acid administered by his own hand during temporary insanity; and to this the jury added a very strong expression of their opinion that he had been driven to this act "by the pressure brought to bear by his partner, Dr. Whitmarsh, using the false charge of Mrs. Bignell as a means to drive him to a dishonorable dissolution of partnership." The town's people paid a marked tribute of respect to the young widow, who, it should be said, throughout the sad affair has maintained her husband's cause with the most steadfast loyalty. On the other hand, Whitmarsh and the woman who made the charges required the utmost exertions of the constabulary for their safe conduct to and from the court, where virtually unchecked displays of opinion occurred over and over again. In which particular again it would almost seem as if there were a good deal of human nature still left in England, and as if the machinery of legal processes did not always work so smoothly as our transatlantic contemporaries would have had us believe during the Guiteau trial. The principal witness adhered to the charge which she made, but on cross-examination allowed that she would not have done anything about it if it had not been for the instigation of Dr. Whitmarsh, who brought the lawyer to her. She also admitted having brought a similar charge against another man two years before, and acknowledged certain facts of her previous history bearing unfavorably on her moral character. A neighbor testified that on the day of the visit the woman told her with much pride and exultation that Dr. Edwardes had kissed her.

In a word, as far as the evidence went, it appears that whether or not Edwardes was indiscreet in his conduct, — and the circumstances are entirely against his having been so, — the accuser was at the best but a reckless tale-bearer, one who "casteth fire-brands, arrows, and death, and saith am I not in sport?" and in all probability was either a blackmailer or a tool in the hands of Whitmarsh. That gentleman, for his part, appears in the unenviable light of one who, having received a large sum of money, not only did not deliver the equivalent but sought to get rid of his dupe in order to have a clear field for repeating the transaction with another victim.

The ruin of this young man is the result of two causes; one, the coldness or rapacity of a fellow practitioner; the other, the scandal of a woman's tongue. On the first point we have little to say at the present time. For the credit of the profession we prefer to believe that such incidents are rare. There should be that *esprit de corps*. that practical exemplification of the golden rule, which, the moment a man is calumniously assailed, should bring to his aid the moral support of his professional neighbors. None of us knows when his own turn will come to be struck by the shafts of malice. One of the amenities of a profession that has many hardships is the promptness and heartiness with which neighborly aid and comfort are extended to those who, without intentional ill-doing, have fallen into trouble.

The other lesson to be drawn from this event is the need of a careful self-protection against the whims of the hysterical and the machinations of the vicious among our female patients.

The only adequate protection is in the presence of a third person in all professional visits, especially when anything of a physical examination is to be made. It is well known that surgical anæsthesia often develops erotic feelings, which may actually leave an impression on the patient of having had an objective source, and physicians know how to protect themselves. The fact that hysteria frequently causes a mental state in which the patient is hardly responsible either for the correctness of her conclusions or the truthfulness of her utterances is not so prominent in the minds of the profession. In such a case the lack of any symptoms of unsound mind may lend to her assertions great plausibility. An English barrister has said that he has known, on more than one occasion, a conviction in a court of law following such apparently straightforward statements of hysterical women, when subsequent developments proved the allegations to have been utterly without foundation. The *Lancet*, in a recent editorial, goes so far as to say that in all cases when charges of impropriety are brought against a medical man by young women the presumption should be against their truthfulness because of the frequency of hysteria, and the tendency in that disease to sexual aberrations. At all events it is obvious that the testimony of a third person, whose presence could generally be secured if insisted on, would be of great assistance to a man suffering under such a charge.

To most young physicians come times when they discuss, with Hamlet, the propriety of suicide, and wonder whether the canon of the Everlasting is really fixed against self-slaughter. Their professional training is not always the best preparation for meeting the ills of life. They know they are unable to judge impartially of their own bodily ills; the necessity of consultation in ills other than corporeal is not so universally appreciated. Dr. Edwardes seems to have made the mistake of brooding by himself over his misfortunes. A few hours in London with his friends would certainly have shown him that the accusation of a mischievous woman could not entirely destroy his character in the eyes of those who knew him best.

The expressions of confidence on the part of his friends cannot recall to life the unfortunate and oversensitive man, but they ought not to be without their lesson upon others whose lot seems beyond endurance. Those whose approval is best worth having, whose confidence is the result of intimate acquaintance, do not surrender their opinions at the idle talk of village gossips, though too often the unthinking and the malicious speak earliest and loudest.

THE WATER SUPPLY OF NEW YORK.

FOR some time past the water supply of New York has been the subject of investigation by a commission specially appointed to consider the matter. The conclusions at which they have arrived, which are interesting to a much larger number of people than are situated within reach of the Croton water system, are as follows:—

That the city requires an increased supply of pure, fresh water; that the work necessary for procuring such supply should be commenced as soon as proper legislation to secure prompt, efficient, and economical execution of this work can be provided; that the Croton water-shed will furnish a sufficient and the best supply for this generation; that the consideration of other sources of supply should be excluded except so far as these may become available hereafter as additions or extensions, and may affect the present construction of these works from the city to and at the basin; and that a new aqueduct should be commenced as soon as proper legislation can be secured.

Among those whose opinion was consulted during the investigation was President Chandler, of the Board of Health, who stated that there was an absolute necessity for more water, and that for a number of years the supply per capita had been rapidly diminishing. He was opposed to the use of water-meters, because the wealthy would be willing to pay for all the water they wanted, while the poor would probably stint themselves in the use of it if they had to pay for the quantity consumed. He said he had no faith in the use of salt water, which could only be introduced at an enormous expense, and could be employed only for washing the streets and putting out fires. It was not possible to get good, wholesome water from artesian or other wells on this island, and the present aqueduct could not supply the demand.

MEDICAL NOTES.

— The autopsy of Gambetta, conducted by some of the most eminent physicians and pathologists of France, showed the cause of death to have been perityphlitis and suppurative pericolitis. There were traces of old inflammation causing stricture of the small intestine at the junction with the ileo-cœcal valve. There was extensive infiltration of pus behind the colon and in the abdominal wall. The wound in the hand, which was popularly supposed to be the cause of death, was completely healed.

NEW YORK.

— Dr. Fordyce Barker having been elected President of the Academy of Medicine for the third time, delivered his third inaugural address at the stated meeting of the Academy held February 1st. During the course of it he mentioned that only twenty-four now remained of the one hundred and eighteen original founders of the Society thirty-six years ago, and at the conclusion of the address Dr. Detmold, one of the twenty-four, gave some interesting reminiscences of the early history of the Academy. The President then introduced Mr. Seymour Hayden, who was the guest of the evening, and who, after presenting his congratulations upon the flourishing condition of the Academy, made some remarks on the advantages of the study of art in connection with the practice of medicine and surgery. When he returned to his legitimate profession, he said, after studying art for two years in Italy, in consequence of a dissecting wound which broke down his health, he became fully convinced of the substantial value of art education to the practitioner. His idea was that in studying art the eye and hand became practiced to such an extent that the matter was of practical utility in the various departments of medicine and surgery. In England many medical men took the same view, and a number of surgeons there were also distinguished artists. Members of the medical profession, he thought, should be æsthetic as well as intellectual students. He believed in a return to the old days when physicians were the leaders of society, and that it was their place "to prescribe for the public, not the public for them." After remarks by Dr. Weir and others the Fellows adjourned to the supper room, where there was a substantial collation, and where they had been invited by the president and vice-presidents of the Academy to join with Mr. Hayden in the "loving cup."

— At the annual meeting of the Board of Managers of the New York Medical Mission, lately held at the rooms of the Young Men's Christian Association, Dr. Alfred C. Post was elected President, Drs. G. A. Sabine and William H. Thomson Vice-Presidents, and Dr. George D. Dowkoutt Medical Superintendent. The expenditures during 1882 amounted to more than $2000, and Dr. Dowkoutt reported that since the opening of the first dispensary, in June, 1881, 4002 cases had been treated at the dispensaries, and 2491 visits made to the sick in their homes. The object of the Mission is to combine religious instruction with the giving of free medical attendance to the poor, and two dispensaries are now maintained by it. It is proposed, if possible, to establish under its auspices an institute, on the model of one in Edinburgh, to train persons for service as medical missionaries in foreign countries.

— The wife of the late Dr. George M. Beard died eight days after the decease of the latter, and from the same cause, pneumonia.

Correspondence.

A LETTER FROM VALPARAISO.

MR. EDITOR, — It may be safely assumed that comparatively few people of our great American republic know what an Anglo-Saxon appearing city is in this busy port of industrious little Chili; but let me state right here that I use the word industrious only in comparing Chili with her sister Spanish-American republics. Valparaiso is the only place in all South America where the vigorous races of the hardy North have set the seal of advancing civilization, and in consequence science is getting a foothold, liberty of action and speech increasing, commerce rapidly developing, and the Jesuit and Dominican are preparing to move. The city was never regularly founded. In 1536 the port was first visited by the Spaniards, and a short time afterward a fishing and trading village gradually developed, till, in 1544, the Santiago government, recognizing the commercial importance of the place, declared it the official port of Santiago.

The city, the general form of which is that of an immense amphitheatre, lies in latitude 33° 2′ S., longitude 71° 45′ W., and consists of two distinctive portions: that upon the coast hills and intervening ravines, chiefly a place of residence, and a long narrow strip bordering the bay at the foot of the hills for several miles, where nearly all the business is done.

The bay is small, semicircular in form, and very deep. From the deck of a vessel in the harbor a splendid view can be had of a certainly picturesque city.

Why the name of *Val de Paraiso* (Vale of Paradise) should have been given to this place, I confess is a mystery to me. The hills are imposing, and may be even called grand, but they are barren and forbidding, and should the place be visited during the fury of a *norther* (a very probable thing in the winter season) paradise would be one's last thought. Taking it throughout the year, however, the climate of Valparaiso is a very mild one, closely resembling the coast climate of middle California. During the present year the highest temperature was only 84° F., in January, the lowest being 51° F., in June. The mean annual range was 62° F. The rainy season commences about the first of June and lasts till the end of September, during which time nine tenths of the annual rainfall occurs. Five inches fell in one day in August, the greatest fall of the year. Earthquakes are occasionally experienced here, the last one occurring July 8, 1872, when a number of severe shocks followed rapidly upon each other, extending forty miles inland, shaking down houses, and causing many fractures and contusions, though fortunately no deaths.

Until within the last eighteen months the water supply of the city was as bad as bad could be. The inhabitants were furnished with water chiefly by breakers carried on the backs of mules from the Salto River, eight

miles away, though a small amount was served to the dwellers on the hills from reservoirs filled during the rainy season. Nearly every house had a water tank holding several days' supply, but these tanks were seldom cleaned, and the system was utterly pernicious. The present water system has been in operation a year and a half, and is a blessing of inestimable value to the city. Water is brought eight miles from the Salto River to a reservoir on one of the hills, from which it is distributed to the lower part of the city. Eighteen hundred houses, containing ten thousand people, are thus supplied. Each house is estimated to contain five people, and as seven hundred and fifty gallons are allowed daily to every house, there is a *per capita* supply of one hundred and fifty gallons. This ratio far exceeds that of any European cities; and Glasgow, which has the largest supply in Great Britain, only gives a daily allowance of fifty gallons per inhabitant. As previously mentioned, only the lower portion of the city is supplied by the Salto water works, but I am informed that it is intended to extend the system to the hills as soon as practicable by means of stationary engines.

The disposal of the city sewage has been a problem of vital importance to the community for many years, growing more and more urgent as the population increased. The difficulty of getting water for efficient flushing prevented, however, the adoption of any modern system till the advent of the Salto works, when a private company contracted to build a proper system of sewers through the lower part of the city, maintaining itself for the present by heavy charges upon those who have drains placed in their houses, and thus relieving a criminally ignorant municipality from all responsibility and expense. The water and drain taxes have become so heavy that healthy houses are an expensive luxury, only to be indulged in by the wealthy.

Nearly all the hill dwellers use earth closets, and the brisk southwest winds blow all ill odors rapidly away; indeed, these winds are the salvation of the city.

The unhealthy season may be said to commence with the rains in June and terminate about a month later than they do. All diseases are greatly multiplied during these winter months, but especially is this true of the scourge of the country, small-pox. The average annual death-rate from small-pox in Valparaiso is 178, all these deaths occurring from June to December. The national authorities have become alarmed at the general spread of the disease, and have taken the matter in hand. An act was introduced into the last Congress making vaccination compulsory, but failed to pass. From the last year's report of the Secretary of the Interior I take the following extract: "During last autumn small-pox spread over all the country, and made numerous victims. It is still very prevalent and shows no signs of abating. In 1881 83,449 persons were vaccinated, and with the object of stimulating the public vaccinators an order was issued in November of last year entitling them to one dollar a day when called to a distance of upwards of four kilometres from their places of residence."

The majority of the practitioners here take little interest in their profession, only looking upon it as a means of gaining dollars and cents. There is no medical periodical published in the city, nor is there a semblance of a medical society. The licensed practitioners are numerous, and are about equally foreign and native, but the "by-ways" are not nearly so crowded as with us. Dr. Page, a Yale man, is the only specialist in the place. He finds time out of a large general practice to devote himself to ophthalmic surgery, and has a very respectable eye clinic.

The hospitals of Valparaiso are entirely unworthy a city of its pretensions. The *Hospital de la Caridad* is the municipal hospital, and is under the direction of the *Beneficencia* society, with a bishop at its head. It is situated at the extreme northern end of the city, against the foot-hills which rise to its rear. It is a large, rambling pile of buildings, constructed after no definite plan, additions having simply been made from time to time to meet the increasing demands of the city. The structures are mostly two storied, carelessly put up, badly ventilated, and miserably served. There are thirteen wards, with an aggregate capacity of six hundred and forty souls. These wards are apportioned, two for women, one for children, five for military patients, one for naval, and four for men generally, and contain from thirty to sixty beds each. The medical staff consists of eight members, each member being both physician and surgeon to his own wards. There is no such thing as alternation in service, neither is there a house-physician nor an interne, so after the usual morning visits the patients are left alone for twenty-four hours. The general service is by the Sisters of Charity. During 1881 there were 5164 patients admitted to this hospital, 3917 discharged, and 1157 died, giving a death-rate of one in 4.4, or over twenty per cent. Of these deaths 607 were from phthisis, one in 1.9, or over fifty per cent., which forcibly illustrates the terrible ravages of the disease in this mild climate. There were twenty-four deaths from hepatitis (probably hepatic abscesses), affording a striking evidence of the highly malarious character of the atmosphere. I was assured by Dr. Cooper, an old resident, that it was common practice here to plunge an aspirating needle into an inflamed liver in search of pus. Should an abscess be demonstrated, it is periodically evacuated till the cavity is obliterated. Should nothing be found, however, no harm is done, the perforation of the capsule often giving marked relief.

The English hospital is nothing more than a large private residence upon the Cerro Alegre, which has been diverted to its present use by Dr. Cooper, whose private property it is. The grounds of this institution are large, bright, and attractive, but the building is dark, depressing, illy arranged, and badly administered. Many radical alterations are necessary here, which are not likely to be made, for it is but natural to infer that a hospital cannot be run in the interests of its patients and be at the same time a remunerative investment to its proprietor. The building accommodates about seventy patients, but is rarely taxed to its full capacity. There were 531 admissions during 1881, 360 being maritime, 152 Chilians, and 19 charity cases. It will be seen from this that the chief support of the institution is maritime, Dr. Cooper having arranged with all the consulates, except the American and German, to receive merchant sailors at a given rate. The mortality for the past year was five per cent., a very good showing. In a private room I saw a case of recent ovariotomy. The patient, a Chilena, thirty-five years old, had had a multilocular cyst of the left ovary, which had been several times tapped. The operation was done by Dr. Cooper under antiseptic precautions, the usual median incision being made. Adhesions

were extensive, and much damage was necessarily done the peritonæum. The pedicle was clamped, and cauterized actually, having a cicatricial button after recovery. No peritonitis ensued, the temperature never getting above 99° F. I saw the patient on the sixteenth day after the operation, when she was walking about, and expected to leave the hospital on the following day.

The German Hospital is located just above the English, and like it is merely a private house, which has been converted into a garden hospital in this instance by a number of wealthy German residents of the city. There are only ten rooms, but the place is lovely, bright, clean, and cozy, and is ably administered by Dr. Thèle, of Berlin, who is also the only medical attendant.

. The mortality from all causes in Valparaiso during 1882 amounted to 5564, a death-rate of 46.3+ per 1000.

There are four cemeteries within the city limits, — three Catholic and one Protestant. They are all situated on the hill-tops, in excellent locations, but the three Catholic ones are administered after the usual pernicious manner of the Romish Church. The city regulations relating to burials are strict enough, and I am happy to say prevent street parades during the day. Those who are able to pay the burial fees of the church can bury their dead from six till ten in the morning, but these fees are far too exorbitant for the majority of the population to pay, who have to inter their dead between midnight and four in the morning. Poverty pursues its victims here even after death, for only the wealthy can afford to buy a lot from the church, and those of moderate means have to rent a grave for a year, after which time the priesthood causes the removal of the body to the *Playa Ancha* (potter's field). The vast majority of the dead, however, are simply carried to the Playa Ancha after midnight, and thrown into one of the open pits.

In concluding, let me call attention to the Protestant cemetery, which every American traveling in these parts should not fail to visit, for here he will see the monument erected a few years ago by the naval officers then in the Pacific, and the Rev. Dr. Trumbull, of Valparaiso, to the fifty-three dead heroes who fell in the Essex during her engagement with the Cherub and Phœbe in Valparaiso Bay, March 28, 1815, to whom honor has been thus tardily rendered.

Yours very truly,

ARTHUR C. HEFFENGER, M. D.,
Passed Assistant Surgeon, U. S. Navy.
U. S. S. LACKAWANNA.

Miscellany.

NEW YORK STATE BOARD OF HEALTH. RULINGS AS TO MIXTURES.

WE last week published a list of exemptions or standards that the New York State Board of Health had adopted under the Food and Drugs Act, then awaiting the approval of the governor.

These rulings have produced no little excitement among manufacturers and dealers of food products, and mainly because it is proposed to require that the proportions of each mixture be stated on the label. They hold that this is a needless interference with trade, and practically makes public the results obtained by experience, the benefits of which belong to the manufacturer.

So long as the adulterants are kept within the limit fixed by the Board, it is held that no public good is to be gained by the publication of proportions.

The English law recognizes this fact, and does not require that proportions shall be stated. We think it right that the label should guarantee that the amount of pure article required by the Board is present; also, that the names of the constituents should be stated, but not the relative proportions. In fact this is an important question, and we should like the views of our readers on it. We believe that some good can be accomplished by an avoidance of extreme measures, and that the Board should do all they can, consistent with their duty, to avoid unnecessary antagonisms. — *Sanitary Engineer.*

ANOTHER CASE OF BLACKMAIL.

APROPOS of our editorial on the Hounslow tragedy on another page, we may mention a somewhat similar case with more fortunate results, which has just received a judicial settlement at Toronto, and which we find described in the *Canada Lancet* for February. An action was brought by a man named Lumb against a medical practitioner of Toronto for having, as he alleged, been criminally intimate with his wife. The doctor had attended Mrs. Lumb in a miscarriage, which took place on the 26th of last June, and the plaintiff alleged that the act was committed on the 19th of July following, while the doctor was treating his wife in his professional capacity, and that she had confessed her guilt to him the same day of the occurrence. The plaintiff estimated the damages at $2000 for the loss of his wife's society and companionship through the trouble, although she still lived with him and took care of her four children. The plaintiff based his case on the evidence of his wife, who swore that the doctor took improper liberties with her, and the evidence of one of the children, a lad of ten years of age, who swore that he looked through the opening between the folding doors and saw the doctor leaning over his mother, and heard his mother say, "What will my husband say." On the part of the defendant evidence was produced to show that the folding doors could not have been open at the time, in fact had not been open for months. The wife's evidence was also shown to be contradictory in many important particulars. Medical evidence was produced to show the improbability that the defendant had connection with her at the time mentioned, twenty-three days after the miscarriage. Witnesses also testified that the character of the plaintiff and his wife was such that they would not believe them on their oath. The judge charged strongly in favor of the defendant, and pointed out that owing to a recent change in the law the evidence of a woman could now be taken in such cases as these, which opened the flood-gates to unlimited blackmailing. The jury, after an absence of less than ten minutes, returned into court with a verdict for the defendant.

Such a ruling and verdict are cause for satisfaction to all physicians as well as congratulation to the defendant, who was willing to incur the odium of publicity and the expense of a suit rather than pay the blackmail demanded.

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 3, 1883.

Deaths reported 2404 (no reports from Chicago, St. Louis, and New Orleans): under five years of age 829: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 486, consumption 354, lung diseases 354, diphtheria and croup 150, small-pox 90, scarlet fever 80, typhoid fever 37, diarrhœal diseases 33, whooping-cough 28, measles 22, erysipelas 17, cerebro-spinal meningitis 13, puerperal fever nine, malarial fevers six. From *typhoid fever*, Philadelphia 13, New York six, Pittsburg four, Baltimore, and Cincinnati three each, Providence two, Boston, New Haven, Charleston, Nashville, Lawrence, and Somerville one each. From *diarrhœal diseases*, New York 14, Boston six, Baltimore three, Brooklyn, Cincinnati, Pittsburg, and Providence two each, District of Columbia, and Charleston, one each. From *whooping-cough*, New York 10, Pittsburg four, Cincinnati and New Haven three each, Boston two, Philadelphia, Buffalo, Milwaukee, Lowell, Chelsea, and Woburn one each. From *measles*, New York 12, Boston and Cincinnati three each, Hyde Park two, Brooklyn and Baltimore one each. From *erysipelas*, New York four, Baltimore three, Philadelphia and Brooklyn two each, Cincinnati, District of Columbia, Pittsburg, Buffalo, Milwaukee, and New Haven one each. From *cerebro-spinal meningitis*, Baltimore, Cambridge, Fall River, and Gardner two each, New York, Cincinnati, Lynn, Holyoke, and Weymouth one each. From *puerperal fever*, Boston two, New York, Cincinnati, Buffalo, Providence, New Haven, Brockton, and Gardner one each. From *malarial fevers*, New York five, Baltimore one.

One hundred and ninety-seven cases of small-pox were reported in Baltimore, Pittsburg one; diphtheria 33, scarlet fever 28, typhoid fever three, in Boston; scarlet fever 17 and diphtheria six in Milwaukee.

In 38 cities and towns of Massachusetts, with a population of 1,018,379 (population of the State 1,783,086), the total death-rate for the week was 20.78 against 20.32 and 19.79, for the previous two weeks.

In the 28 great towns of England and Wales, with an estimated population of 8,620,975, for the week ending January 20th, the death-rate was 23.4. Deaths reported 3862: acute diseases of the respiratory organs (London) 389, whooping-cough 97, scarlet fever 86, measles 82, fever 56, diarrhœa 40, diphtheria 22, small-pox (London three, Newcastle two, Nottingham and Derby one each) seven. The death-rates ranged from 13.9 in Cardiff to 31.4 in Manchester; Plymouth 16; Bristol 19.9; Birmingham 20.2; Brighton 21.1; London 21.9; Wolverhampton 22.9; Birkenhead 23.5; Sheffield 26; Hull 29; Leeds 30; Liverpool 30.7. In Edinburgh 23; Glasgow 30.4; Dublin 25.5.

For the week ending January 13th, in 169 German cities and towns, with an estimated population of 8,459,496, the death-rate was 25.8. Deaths reported 4199: under five years of age 1851; consumption 640, lung diseases 499, diphtheria and croup 215, diarrhœal diseases 146, scarlet fever 81, measles and röthein 51, whooping-cough 45, typhoid fever 42, puerperal fever 15, small-pox (Königsberg, Kiel, Heilbronn, Cologne, Rheydt, and Mainz one each) six. The death-rates ranged from 11.1 in Kassel to 40.1 in Chemnitz; Königsberg 35.1; Breslau 37.3; München 29.7; Dresden 22.2; Berlin 22.4; Leipzig 23.7; Hamburg 31.2; Cologne 23.4; Frankfort a. M. 19.7; Strasburg 27.3.

For the week ending January 20th, in the Swiss towns, population 494,390, there were 26 deaths from consumption, lung diseases 21, diarrhœal diseases 15, diphtheria and croup 12, typhoid fever five, scarlet fever one, whooping-cough one, erysipelas one. The death-rates were, at Geneva 9.2; Zurich 8; Basle 19.8; Berne 23.7.

The meteorological record for the week ending February 3d in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps:—

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 2, 1883, TO FEBRUARY 9, 1883.

DELOFFRE, AUGUSTUS A., captain and assistant surgeon, will be relieved from duty in the Department of the Missouri, and report in person to the commanding general, Department of the East, for assignment to duty. Paragraph 3, S. O. 26, A. G. O., January 31, 1883.

ELBREY, FREDERICK W., captain and assistant surgeon. The leave of absence on surgeon's certificate of disability, granted July 21, 1882, is extended six months. Paragraph 5, S. O. 26, A. G. O., January 31, 1883.

NOMINATIONS. — The following gentlemen were nominated by Governor Butler as State Trustees of the Massachusetts General Hospital: Henry P. Kidder, Dr. C. V. Bemis (reappointed), Richard Olney, Dr. Henry G. Clark (instead of S. D. Warren and William Endicott, Jr.).

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at No. 19 Boylston Place, on Monday, February 19, 1883, at eight o'clock P. M. Reader, Dr. E. D. Spear. Subject, Otitis Media Purulenta.

C. M. JONES, *Secretary.*

SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION FOR OBSTETRICS AND GYNÆCOLOGY. — There will be a meeting of this Section at 19 Boylston Place, on Wednesday, February 21st, at eight P. M. The following papers will be presented: Dr. O. W. Doe, A Case of Galactorrhœa. Dr. C. M. Green, The Delivery of the Second Fœtus in Labor with Twins.

J. B. SWIFT, *Secretary.*

BOOKS AND PAMPHLETS RECEIVED. — Seventeenth Report of the Board of Trustees of the Connecticut Hospital for the Insane. State of Connecticut. 1883.

Suicides in New York city during the Eleven Years ending December 31, 1880. By John T. Nagle, M. D. New York. (Reprint.) 1882.

Transactions of the Thirty-Sixth Annual Meeting of the Ohio State Medical Society. 1882. Columbus.

Papstykker til Chromatoptometrisk Tabel af Dr. Ole B. Bull. Pris pr. Par 18 Ore netto. (Uden denne Emballage tages intet Expl. tilbage.) P. T. Mallings Boghandel.

Primary Antiseptic Occlusion in Military Practice, with Cases from the Big-Dry-Wash Fight, near General's Spring, Arizona, July 17, 1882. By H. I. Raymond, A. M., M. D., U. S. A. (Reprint.)

Annual Address delivered before the American Academy of Medicine at Philadelphia, October 26, 1882. By Traill Green, A. M., M. D., President of the Academy. Philadelphia. 1883.

Second Annual Report of the State Board of Health of New York. Transmitted to the Governor February 8, 1882. Albany. 1883.

Lectures.

ON HYDROTHERAPEUTICS.[1]

BY PROFESSOR DUJARDIN-BEAUMETZ,

Member of the Academy of Medicine, Physician to the Hôpital St. Antoine, etc., Paris, France.

GENTLEMEN, — Applied from the earliest antiquity to the treatment of certain affections, cold water did not take its proper place among the resources of our profession till almost the very epoch in which we live. It was as a result of the efforts of a simple peasant, a kind of country quack, and not till after his empirical employment of the remedy, that scientific labors were undertaken to explain the effects, and to determine the indications of cold water applications.[2]

At Graefenburg, a village of Austrian Silesia, lived, at the commencement of this century, a certain Priessnitz, a very observing and intelligent man, who had noted the beneficial effects of cold water treatment on sick animals confided to his care.

Imagining that diseases impregnate a man as liquids do when they penetrate a sponge, he maintained that in order to cure them it sufficed to remove morbid impurities from the cutaneous surface by repeated bathings and the promotion of the excretory function of the skin. He therefore applied cold water to the treatment of the greater part of diseases, and modified successively the divers procedures of hydrotherapy which he put in practice. At first he employed sweatings followed by cold affusions, then advised wrapping the patient in a wet sheet, and, finally, cold baths. He obtained by this mode of treatment marvelous cures, which spread his fame far and wide.

Soon were seen flocking from all parts of Europe sick people seeking remedial aid from the healer of Graefenburg, and the village hovels disappeared to make way for numerous hotels, which soon became insufficient, so great was the number of patients, which kept increasing every day. Moved by this success, the Austrian government shortly appointed a commission which gave officially to Priessnitz the direction of the "hydropathic" establishment, which he had founded, and a few years after the institutor of hydrotherapeutics died crowned with fortune and with glory.

Such is the curious beginning of modern hydrotherapy, which, it will be seen, owed its popularity to the most gross empiricism. More recently the labors of Scoutteten, of Schedel, of Fleury, of Beni Barde, in France; of Chiapponi, in Italy; of Johnson, and of Manby Gully, in England; of Bell and Nicanor Rojas, in America; of Roser, of Lersch, of Pleniger, in Germany, have given a strictly scientific and medical character to the study of hydrotherapeutics, and it is from their contributions that I shall draw material for the several considerations into which I now enter.

PHYSIOLOGICAL ACTION OF COLD.

Numerous investigations have been made the last few years into the physiological action of cold, and of cold water in particular. I shall refer more especially to the valuable study of Winternitz.[3]

Whenever you apply a cold substance, such as ice or cold water, to any part of the body, you determine perturbations in the nervous system affecting the cerebro-spinal axis, and especially the great sympathetic. These phenomena are variable as the application of the refrigerant is of greater or less duration; if the chilling be of short duration, the tactile sensibility is at first augmented; if it be prolonged, all the modes of cutaneous sensibility disappear; a fact which has been utilized in the production of local anæsthesia for minor surgical operations. If, finally, you cease the refrigeration the sensibility, appears anew with a certain degree of hyperæsthesia.[4]

But the most profound modification, and that which effects the most happy results, from the stand-point of therapeutics, is the perturbation occasioned in the vasomotors. Under the influence of reflex action,[5] following cold water applications, the capillaries are seen to become constricted, the peripheral heat to diminish, the cutaneous secretion to cease, the skin to become pale, the muscular elements to contract, giving rise to the phenomenon known as *goose skin*; at the same time

[1] Translated from advance sheets by E. P. Hurd, M. D., of Newburyport, Mass., and now published for the first time.

[2] Hippocrates, in his treatise on "Air, Waters," etc., insists on the uses of cold water in the treatment of diseases. The Romans made great account of hydrotherapy, and a certain Charmis maintained that all diseases were curable by cold water alone. Celsus, Aretæus, Cœlius Aurelianus, all pronounced in favor of cold water medication, and recommended treating fevers by this means. Then it fell into desuetude till the seventeenth century.

In 1638 Louis Septala recommended cold douches; then a Belgian, Hermann Van der Heyden, employed them in all diseases, and Foyes, an Englishman, advocated hydrotherapy with great enthusiasm.

In 1712 appeared a dissertation by Frederic Hoffman, having for title, *De aqua medicina universali*, and showing the marvelous success which attends the therapeutic use of cold water; the system of treatment advocated spread rapidly in Germany.

In Great Britain, Wright, Gregory (of Edinburgh), and especially Currie, all of whom attempted a physiological explanation of the action of cold water, gave a powerful impulse toward the employment of this method.

In Italy, Giannini, Vallisnieri, Cocchi became partisans of hydrotherapy. [This was about the middle of the last century.] Pomme, who wrote in 1765, was about the only French exponent of the new method. Then comes the era of Priessnitz, who, early in this century, gave so great an impetus to the water treatment, and stimulated scientific inquiry, the results of which are seen in the numerous and able physiological treatises whose authors are mentioned in the text.

[3] Winternitz, Die Hydrotherapie auf Physiologischer und klinische Grundlage, Vienna, 1877.

[4] Cold raises, lowers, or abolishes the excitability of the sensory nerves, and Richardson has shown the modifications, varying according to the duration of the refrigeration. When the temperature of the skin is a little below 35° C. vascularization becomes more active, and sensibility more exquisite. When the integument is cooled still more, sensibility undergoes diminution, and at eight degrees below zero it is abolished altogether, to reappear as the temperature returns to the normal.

These modifications of temperature have been noted by Winternitz, and with the æsthesiometer of Sieveking by Helmholtz, by the determination of the quickness of our sensory impressions. From 36° C. to 38° C. this velocity is seventy-two metres a second; with lowering of the temperature it becomes ten times less.

These same modifications of sensibility are produced when the cooling body is applied to the trunk of a nerve of sensation, and these applications produce first hyperæsthesia, then a period of complete anæsthesia.

The experiments of Waller, of Rosenthal, of Eulenburg, of Weir Mitchell, etc., are very instructive and convincing. Richardson, "Action of Extreme Cold on the Nervous System," Medical Times, vol. ii., 1825. Winternitz, op. cit. Waller, On the Symptoms produced by the Application of Cold to the Sciatic Nerve. (Arch. Gén. de Méd., 5th series, vol. xx., p. 346, 1862.)

Eulenburg, Lehrbruch der Functionnellen Nervenkrankheiten, Berlin, 1871.

Weir Mitchell, Injuries of Nerves and their Consequences, Philadelphia, 1872.

[5] Edwards, Brown-Séquard and Tholozan, and Vulpian have shown that when the hand is plunged into cold water the temperature of the other hand is lowered or elevated. Brown-Séquard has, moreover, remarked that the reflex phenomena determined by local applications of cold to the skin are produced in a point symmetrical to that where the local application was made. Dumontpallier has quite recently insisted upon the study of the localization of the æsthesiogenous parts of the skin. Edwards, De l'Influence des Agents Physiques sur la Vie, Paris, 1824. Brown-Séquard and Tholozan, Recherches Experimentales sur quelques uns des Effets du Froid. (Arch. Gén. de Méd., 5th series, vol. xii., p. 683, 1858.) Dumontpallier, Leçons sur les Actions Reflexes. (Un. Méd., 1880.)

the heart's pulsations diminish, the arterial tension augments, as Delmas, of Bordeaux, has shown, and the patient experiences a general chill.

All these symptoms disappear with a rapidity proportioned to the duration of the exposure to the action of the cold. To this period succeeds another assemblage of symptoms to which has been given the name of reaction, a reaction which is characterized by manifestations of an opposite kind. The skin becomes red, animal heat is raised, the secretions augment, the muscular functions acquire a new energy, and a quite special sensation of *bien être* is experienced. It is in this double action on the nervous system that we must seek an explanation of the effects of hydrotherapy, whether considered as an antipyretic, a nerve tonic, or simply as a means of hygiene.

I will leave at one side for the present the antipyretic effects of cold water, to which I shall return when I shall speak of the treatment of fever by cold baths, and I shall at the present time limit myself to the effort to set clearly before you the results which may be obtained in nervous diseases from the double physiological action above mentioned.

ACTION ON THE NERVOUS SYSTEM.

In order that the functions of the nervous system may be accomplished in a regular manner, there must be not only complete integrity of all the constituent parts of that system, but it must receive a uniform and sufficient supply of normal arterial blood. When one of these conditions is at fault immediately modifications, more or less profound, in the nervous system result. This first fact being posited, we may immediately deduce consequences of the most positive kind from the stand-point of hydrotherapy, which acts on the nervous system, on the circulation, and on the nutrition.

On the nervous system by the sudden perturbation which it causes in the functioning of the sensory and motor nerve apparatus, hydrotherapy reëstablishes the regular operation of the cerebro-spinal axis; it, moreover, brings into exercise the vaso-motor centres, and thus produces an equilibrium between the functions of the brain and spine on the one hand, and the great sympathetic on the other. Moreover, it attenuates the exclusive action of certain local affections, which, by reason of reflex influences, become the point of departure of important secondary perturbations of the brain and spine.

By its action on the circulation, which it regulates and renders active, hydrotherapy still further modifies in a happy manner the functions of the brain and spine. Finally, by its general effects on nutrition,[1] by its direct or indirect action on the vaso-constrictors and vaso-dilators, on the secretory nerves, and lastly on the trophic nerves, cold water stimulates nutrition, promotes the regular play of the different organs, and becomes one of the most active agents of tonic and reconstituent medication. Under its influence the globules become richer in hæmoglobin, the oxygenation of the blood more active; and we ought to make a capital point of this fact in the treatment of diseases of the nervous system.

[1] Kund has experimented on the influence of cold in cases of poisoning by strychnia. Frogs poisoned by this medicament, he placed, some in water at 34° C., others in very cold water. The muscles of the former very speedily returned to their state of physiological relaxation, those of the latter, exposed to a low temperature, kept their tetanoid state a long time. The same experiments have been repeated in cats with like results. Kund, Gaz. Med., 1857.

Such is the veritable effect of hydrotherapeutics in nervous affections. I know that there has been much discussion as to whether the action of cold water were sedative, excitant, or perturbing. Some, with Trousseau, have pretended that cold water is the best of sedatives; others, as Fleury, have affirmed its excitant action; others, with Bloch, its perturbing action. These are, I opine, trivial questions, for according as you consider the effects of cold water during its application, or after its application, you observe opposite symptoms, and that it may be at one time perturbing, at another excitant or sedative.

MODES OF APPLICATION.

It is not enough to know the physiological or therapeutical effects of cold water, you must understand the conditions to be fulfilled in order to obtain the most favorable effects. I am, then, going to enter somewhat into details which I believe are of importance, for we have seen physicians prescribe hydrotherapy without insisting either on the mode of application, or on the duration of the douche, or on the temperature of the water. It is necessary, on the contrary, that you should carefully determine all these points in your directions, and that you should not leave, as is often done, to persons who are strangers to the healing art the management of the hydrotherapeutic treatment.

The means of application of cold water are numerous; these may be arranged in three distinct groups: In the one the water is delivered under high pressure, in the second there is no pressure, in the third the applications are made to the naked body by means of cloths or sponges. I shall then speak of three modes of application — douches, baths, and lotions.

DOUCHES.

Douches are by far the most employed. They are divided into a number of varieties, which depend on the apparatus by which they are administered. We have, then, the *douche en pluie*, or shower bath; the *douche à colonne*, in which a column of water is let fall upon the body; the *douche à lame concentrique*, in which three or more concentric streams are directed on some portion of the body surface; the *douche en nappe*, in which the water comes in sheets; the *douche en cercle*, in which a circle of jets plays upon the patient; the *douche en jet mobile*, in which a varying direction is given to the jets. I need not occupy much of your time with a consideration of these douches; you are familiar with them all. In the shower bath the douche is applied by means of a large globe sprinkler (*pomme d'arrosoir*); in the *douche à colonne* the water descends with some force by a circular opening; in the third variety the globe sprinkler, instead of being pierced with a multitude of holes, has several circular chinks through which the water pours; in the *douche en nappe* the watering globe has the form of a bell; in the *jet mobile* a tube of leather or caoutchouc enables one to give a varying direction to the stream. The most used of these douches are the *douche en pluie* and the *mobile jet* douche.

In general, the stronger the pressure of the water, the less painful the sensation of cold. At the same time care is needed in the management of the pressure, which, when too violent, produces painful traumatisms. In the shower bath the douche strikes more especially the upper part of the body, and you ought to avoid, save in exceptional cases, douching the head. As for

the *douches en jet* (the jet sprays), you can make use of different attachments which modify the form of the jet, and give the full jet or the broken jet, which may be directed, according to circumstances, on different parts of the body.

It remains for me to say what should be the temperature of the water, what ought to be the duration of the douche, what preparation the patient should make before, what he should do after, the douche.

As far as the temperature is concerned, the douche may be cold, it may be tempered, or it may be alternately cold and warm. The colder the douche the more intense the reaction, the more painful, too, the application of the douche. So in very susceptible subjects, and those who experience under the influence of cold a painful sensation of cardiac constriction and of suffocation, it is better to have recourse to tempered douches. In administering these douches a jet of cold water and a jet of hot water are turned by means of stop-cocks into the douche apparatus, and you can at your pleasure vary the temperature of the douche. Ordinarily at the commencement of the douche the water is tempered to 25° C. (77° F.), and is lowered during the douche so that finally it is not more than 10° C., or 15° C. (50° F. to 59° F.).

In the douches alternately hot and cold a much more active physiological reaction is obtained. In the so-called "Scotch douche" you begin with a douche of the temperature of 30° C. (86° F.), and gradually raise the temperature to 50° C. (122° F., which is about as hot as can be borne), then you give immediately a douche about as cold as ice. There is another kind of alternating douche in which a succession of warm and cold douches is given to the patient.

DURATION OF THE DOUCHE.

The douche ought always to be exceedingly short. You have just been told that the favorable results of hydrotherapeutics are due to a double action on the nervous system; to obtain this double action the impression of cold must be of short duration. As a general rule its duration should not exceed thirty seconds, and the first application of cold douches ought not to exceed ten or fifteen seconds.

PREPARATION FOR THE DOUCHE.

There are certain rules which should govern the patient before, during, and after, the douche. The greater the difference between the temperature of the body before the douche and that of the water, the more active the reaction will be. It has therefore been advised to cause the patient to take vigorous muscular exercise before the douche, in order to induce some degree of sweating. In our great gymnastic establishments, where the happy idea of douche compartments for the public benefit finds realization, it is at the moment of greatest muscular activity that the douche is taken.

This important condition, to have the skin in a state of perspiration, in order to derive from cold douches all their desirable effects, is little known, not only to the public, but also to physicians. Does not everybody in fact maintain that a cold bath taken when one is sweating is a bad thing, and that it is to this cause that are due the evil effects which sometimes follow the free external use of cold water? I believe this to be a complete mistake; and if we occasionally see congestions of the lungs follow a cold plunge, it is more probable that the individual was chilled before the bath was taken, than that the pulmonary congestion resulted from the bath.

Elsewhere we see, as a medicinal measure, a disposition manifested to favor as much as possible this state of sudation by exercise and artificial means. As artificial means, in Germany they make great use of the *dry blanket*, the patient being enveloped in several blankets thoroughly tucked around him, and kept in the hot, dry, sweating room, or subjected to a powerful vapor bath till a state of free perspiration is induced; then the wrappings are removed and a cold douche is administered, or he is immersed in a bath of cold water. The Russian bath, so much in use among a great many nations, and of which we possess in Paris a very complete establishment, the Hamman, is based entirely on this double action of heat and of cold water.

During the douche the patient ought, as Beni Barde recommends, to suppress, as much as possible, strong contractions of the muscles, and keep a firm hold of the bar for support. The respiratory distress is mitigated by freedom in outcries. In the event of congestive tendencies to the head or to the uterus, it is well to take a warm foot-bath, or douche the lower extremities with warm water, after the cold douche.

IMMERSIONS.

When remedial effects are sought from immersions, the patient either takes a single plunge into cold water, which should be of sufficient depth that the whole body may be immersed, then immediately rubs himself dry till the skin glows, or he remains several minutes in the bath; the latter course is recommended when an antipyretic effect is desired.

Partial baths are often beneficial, such as foot-baths, sitz-baths; those with running water, furnished with implements for local douching, are preferable.

AFFUSIONS AND PACKING IN THE WET SHEET.

Affusions consist in pouring cold water on the naked body of the patient, or in what is called the wet pack. Wrapping the patient in wet blankets is a very active hydrotherapeutic method. It has this advantage, that it may be employed in all places, and without having recourse to the quite complex apparatuses just described. It is, however, a painful application, and is by no means free from danger. The mode of procedure is simple enough: You wrap the patient in a sheet that has been wrung out of icy-cold water, — you may apply the wet sheet with the patient standing or lying, and keep him thus enveloped ten to fifteen seconds, — then with brisk rubbing with dry cloths you try to promote vigorous reaction. This envelopment may be partial; in this case it has been advised to leave the wrappings on during the entire period of reaction.

Such are in general the methods of application of cold water. There are other modes of using cold from a therapeutic point of view, and I shall now speak of applications of ice and pulverizations of ether.

It has been advised to treat certain neuroses by the application of ice the whole length of the vertebral column, and in England chorea is much treated by this method, and so is hysteria. Charcot has even attempted this method at the Salpêtrière, the ice being placed for the space of a half hour, then an hour, over the ovarian region in hysterical patients. By this mean she has observed a diminution in the number and intensity of the attacks.[1]

[1] Experiments have been made by Weir Mitchell, and by Richardson, to determine the direct action of cold on the spinal cord, the brain, and the cerebellum.

Cold destroys the vital properties of the cerebro-spinal axis when

A physician of Varsovie, Lublesky, has advised another means of producing refrigeration — the application of ether spray the whole length of the spinal column. He has thus treated chorea.

Such, gentlemen, are the divers applications of cold in the treatment of nervous diseases. In the next lecture I shall treat of electricity in the same affections; a subject much more complicated, and which will require much persevering study to master.

TWO CASES OF COLOTOMY.[1]

BY J. COLLINS WARREN, M. D.

ALTHOUGH this operation is very frequently performed at the present time, it is not easy to obtain a description in the books which will serve the purpose of a useful guide to the surgeon who is about to undertake his first case of this kind. The best description in the English language is furnished by Allingham, so far as the writer is aware, and he is freely quoted by Bryant. A painstaking and accurate account is given by Koenig.[2] Allingham's rules are: to make an incision beginning one and one half inches to the left of the first spine below the last rib, and running five inches obliquely downwards and forwards across the space between the last rib and the crest of the ilium. Some writers content themselves with saying that the middle of the incision should correspond with the highest point of the *crista ilei*. The length of the incision is occasionally given as three inches. This is about the length of that drawn in Bourgery's plates of Amussat's operation. Packard, in the American edition of Holmes, considers this length sufficient. It is his custom, he informs me, to begin the incision at the depression made by the edge of the quadratus lumborum muscles. Inasmuch as the bowel lies at the edge of the muscle, this would bring the objective point near the beginning of the preliminary incision and not under the centre, as it should be. Moreover, some anatomists affirm that the depression supposed to be caused by the quadratus is really produced by other muscles. Allingham calls attention to the fact that it is sometimes quite difficult to find the bowel, and gives as a guide the direction to draw a line from the anterior to the posterior spinous processes, to extend a line vertically from a point one half inch behind the centre of this line, and it will be found to lie directly over the bowel. The bowel may be opened in the groin according to Littré's method, and modern surgery has deprived this operation of its principal danger, the opening of the peritonæum.

Another method of getting at the colon, described by Fine, consists in making a vertical incision from the eleventh rib to the crest of the ilium through the abdominal walls and opening the colon within the peritonæum.

The precaution sometimes given not to open the bowel in these operations until it has become glued to the lips of the incision seems hardly necessary.

The first case was that of a German girl, twenty-three years of age, who entered the Massachusetts General Hospital with symptoms of disease of the rectum of one year's standing. She was suffering great pain in defecation, and a digital examination showed the lower rectum to be almost completely obstructed by an indurated growth. The patient was etherized a few days later, and the constriction relieved by an incision which completely divided all tissues between the anus and coccyx, including the lining of the bowel and skin. Great relief followed, but in a week or two the symptoms of stricture returned, and it was found that the disease had already extended above the incision. Colotomy was performed on May 24th, Allingham's directions being carefully followed. The bowel was found without difficulty, was caught up by two loops of thread, and the incision stitched together around it. The colon was then opened, and after a very abundant fæcal discharge had taken place was stitched to the edges of the opening left for that purpose. The operation was done with antiseptic precautions, as a slight attack of erysipelas had followed the previous operation. Drainage tubes were inserted at each end of the incision, and a dressing of oakum folded in carbolized gauze was placed over the wound and changed as often as necessary. Except a slight erysipelatous blush lasting a few days recovery was uninterrupted, and the patient was discharged from the hospital June 24th, with the wound entirely healed. There was no inconvenience from leakage from the bowel, although occasionally a small amount of fæcal matter escaped with the morbid discharges from the rectum. There were two natural movements from the bowel daily, and there was complete relief from the previous suffering. During the summer the patient reported herself at the hospital. The movements continued to be well-formed and regular. The disease continued to progress, and she died on January 1st, having been obliged to resort to opiates only a few days before death.

Colotomy was performed in the second case for congenital absence of the rectum. The child, a patient of Dr. W. A. Dunn, was born two days before, and all attempts to open the bowel through the anal orifice were unavailing. The so-called paradox of M. Huguier occurring to my mind, namely, that in infants the sigmoid flexure is in the *right* groin,[3] I selected that position, found the distended bowel without difficulty, and evacuated a large amount of meconium, relieving the enormously distended abdomen. All symptoms were speedily relieved, the child nursed well, and the wound

it is too long applied. The first effect of chilling the cerebrum is a brief sedative action. Then phenomena of motor excitation are developed, sensibility is lessened, and if the application of cold is continued, the animal falls into a profound stupor, and surgical operations may be performed on him without the least movement. This state resembles the hibernal sleep.

When refrigerant applications are made over the cerebellum of birds, backward movements are produced of a very marked character, the explanation of which has not yet been satisfactorily given. According to some they are due to the cerebellum serving as counter-poise to the opto-striate bodies which contain the centres for backward movements. According to Richardson, the cerebellum is the seat of instigation of forward movements, and when its action is suppressed, backward movements take place.

When cold is applied to the medulla oblongata, the respiratory movements are first tumultuous, then they are slowed, and finally cease altogether. Bourneville, De l'Emploi de la Glace. (Progrès Médical, 1876.)

healed without any indications of unusual inflammation. A progressive emaciation soon set in, which continued in spite of the baby's ability to nurse well, and death occurred on the fourteenth day. Unfortunately, Dr. Dunn was unable to procure an autopsy and settle the point whether the ascending or descending colon had been opened. Taking into consideration the fact that it has been shown that the position of the sigmoid flexure described by Huguier is found in a comparatively small percentage of cases, and that when the ascending colon is opened marked emaciation occurs, as has been pointed out by some writers, it seems quite possible that the ascending colon was opened in this instance, although the rapid and abundant discharge of fæces made it seem probable at the time of the operation that the opening had been made near the fundus of the cul-de-sac.

In looking up the literature of this subject after the operation, the proposition of McLeod struck me most favorably, and that is, to perform abdominal section when the rectum is wanting, free the end of the bowel from its connections, and, having emptied it, bring it down and stitch it to the anal opening. This is certainly a severe operation, but it seems to me preferable to all other alternatives.

The treatment of cancer of the rectum deserves a word in connection with the case first reported. In this neighborhood it has been the custom to adopt chiefly an expectant method, the stricture, if marked, being relieved by the passage of bougies; in England colotomy is almost universal; in Germany extirpation is largely resorted to. A linear division of the stricture, which I have performed in a number of cases, brings only temporary relief. A radical operation can, of course, only be attempted with reasonable hope of success in the earlier stages of the disease, but it is important to recognize the fact that the terrible suffering peculiar to cancer in this locality can be greatly relieved by an opening in the bowel at some point above.

NEPHROTOMY FOR HYDRONEPHROSIS. RECOVERY.[1]

BY A. T. CABOT, A. M., M. D.

Surgeon to Out-Patients in the Massachusetts General Hospital; Surgeon to Children's Hospital.

WILLIE H., aged ten, was admitted to the Children's Hospital, April 15, 1882, with the following history: Three months ago he fell down-stairs during an attack of dizziness. For two or three days he passed bloody urine. This soon stopped and he got rapidly better, and was able to be about, but was short of breath. Several weeks after the fall he noticed a swelling on his right side. This swelling has since steadily increased in size, but he has never had any pain nor discomfort from it.

The child is sallow and appears dull and listless. Dr. Watson, who first saw him in the out-patient department, found a prominent fluctuating tumor filling the right side of the abdomen and reaching to the median line. This tumor was dull on percussion; the dullness being continuous with the liver and kidney dullness, and reaching downwards to within an inch of the anterior superior spine of the ilium.

[1] Read before the Surgical Section of the Suffolk District Medical Society, January 3, 1883.

April 18th. Dr Langmaid etherized the child and introduced an aspirator needle into the tumor. He drew off forty-four fluid ounces of clear, slightly yellow fluid, which was analyzed, with the following result: specific gravity 1007; reaction alkaline; albumen one fourth per cent.; sugar absent. The sediment contained large, round cells, and signet ring cells, with red and white blood corpuscles in varying stages of destruction.

April 27th. The fluid had reaccumulated, and Dr. Langmaid again aspirated, obtaining several ounces of a fluid like the last, but tinged with red. This fluid was found to contain urea in small amount.

On May 1st, when I took charge of the wards, the tumor was again large and prominent, and fluctuation was distinctly felt from the abdominal surface through to a point just above the crest of the ilium behind.

May 6th. A consultation with the other surgeons of the staff was held, and incision and drainage of the sac was decided upon.

I accordingly made an incision vertically upwards from the crest of the ilium, along the outer edge of the quadratus lumborum. Upon cutting down carefully through the muscles the cyst wall came into view, and was incised and stitched to the skin. The finger passed into the cavity felt a soft, nodular mass, probably the kidney in the posterior part of the cyst. The ureter could not be detected.

Between two and three pints of amber-colored fluid escaped. A double drainage tube was inserted, and a Lister dressing applied, the operation having been done under spray with all antiseptic precautions.

The fluid was analyzed by Professor Wood, with the following result: reaction slightly acid; specific gravity 1008; indican present; urea present; chlorine present; uric acid present; albumen large trace. The sediment contained blood corpuscles, leucocytes, an occasional triple phosphate crystal, round cells resembling renal epithelium, and cylinders resembling hyaline casts.

May 7th. Recovered well from the ether. The temperature is 101° F., whereas after each of the aspirations it rose to a little above 103° F. The discharge is considerable, and the dressings are changed antiseptically.

May 8th. Quite restless last night, but has no pain. The urine is smoky in color, and the carbolic acid is discontinued, and liquor sod. chlorinatæ one part, water ten parts, is used in its place.

At this time, when the urine was dark, the watery fluid escaping from the wound colored the dressings a bluish-black appearance, just as the urine colored the cloths with which it came in contact. After the discontinuance of the carbolic acid the urine soon resumed its natural color.

The wound was dressed regularly, at first each day, later every second day, and the child continued to do well in every respect.

May 28th. An error of digestion sent the temperature to 104° F.; but on the following morning it again came down nearly to normal, as it had previously been.

The discharge, which was mainly watery, with very little purulent character, steadily diminished in amount. During May and June the boy was up and playing about the ward, and finally, June 14th (five and a half weeks after the operation), the tube was removed and the wound quickly closed.

June 19th. He went to the Convalescent Home at Wellesley, and on July 3d he finally went home with no sign of his former trouble, beyond the scar of the incision in the lumbar region. He has since been constantly heard from and has remained perfectly well.

The diagnosis in this case was tolerably certain.

The fall was followed immediately by bloody urine, and the gradually increasing tumor was noticed soon after this. The comparatively rapid growth of this tumor to a considerable size, with absence of pain and tenderness, and with perfect fluctuation felt over its whole surface, made its cystic character evident. The preceding hæmaturia strongly suggested the kidney as the seat of its origin. Finally, the character of the fluid removed, containing as it did urea, with but little albumen, placed the existence of hydronephrosis beyond question.

It is interesting to notice that at each withdrawal of fluid the amount of urea and other urinary constituents became more and more appreciable, while the albumen decidedly diminished in amount. This increase of urea has been previously observed in these cases, and is the natural result of relieving the pressure upon the kidney.

Also during the carbolism after the operation the urine flowing from the wound was similarly colored with that from the bladder. This shows that the kidney retained a very fair degree of activity, and that the ureter must have again become pervious before the fistula in the side closed, otherwise we should have had a reaccumulation of fluid.

A daily measure of the amount of urine passed was attempted, but could not be made exact, owing to an attack of diarrhœa, necessitating frequent use of the bed-pan when the sister in charge was not in the ward. We found, roughly however, that after the operation the urine gradually increased in amount, but remained always rather below normal.

The proper operative treatment of hydronephrosis is a recent and still unsettled surgical problem. The three methods of treatment which have been employed with more or less success are aspiration or tapping, removal of the kidney (nephrectomy), drainage by antiseptic incision (nephrotomy).

In Ziemssen's Cyclopædia of Medicine (American edition) Ebstein says, in regard to the treatment of hydronephrosis, that the results of the operative treatment of this disease are thus far not exactly encouraging, and as a general rule we shall be justified in having recourse to such means only when life is threatened. Further, he says that the puncture of hydronephrotic sacs is dangerous because an outbreak of peritonitis is always to be feared.

This opinion was expressed at a time when the importance of antiseptic methods was not appreciated, and in recent journals several cases are reported in which cures have been obtained by successive aspirations of the sac.

Hicks [1] and Croft [2] have each reported a case of cure after aspiration. Both the patients were boys (ages eleven and twelve), and the hydronephrosis was in both cases of traumatic origin. Three aspirations were required in one case, eight in the other.

Doe [3] has reported the case of a woman with a nodular stricture of the rectum, probably cancerous, with coincident hydronephrosis, in which, after two aspirations, the renal tumor did not reappear while the patient remained under observation.

The most distinguished advocate of the total extirpation of the kidney in these cases is Mr. Knowsley Thornton. He prefers the operation by abdominal incision, and uses that described by Langenbuch along the outer edge of the rectus muscle. By this incision he claims that the parts are much better exposed, and that the surgeon can advance understandingly to the enucleation of the tumor, whereas with the lumbar incision the space is small, and the operator is hampered in his movements.

In a clinical lecture reported in the *Medical Times and Gazette* of May 6, 1882, he says, "To sum up, then, I would recommend that the lumbar incision be used only for cases in which there is a strong suspicion that a calculus is present, and that the operation will end in nephrolithotomy; and I should be disposed in any case in which I had commenced by the lumbar incision and then found it necessary to complete the nephrectomy to do so by Langenbuch's incision, utilizing a portion of the already made lumbar incision for drainage, and closing the remainder."

"I would in all other cases, such as neoplasms of the kidney, hydronephrosis, pyonephrosis, and floating kidney, operate by abdominal section, making the incision along the outer edge of the rectus abdominis instead of in the median line."

Lastly, in regard to the treatment by incision and drainage.

Czerny, who read a very complete paper on the surgery of the kidney at the International Medical Congress, held in London two years ago, says that incision of the cyst and stitching the edges of the opening to the skin is the best plan in cases of fixed hydronephrosis, pyonephrosis, and echinococcus, while extirpation is indicated in cases of wounds of the kidney, floating kidney, pyonephrosis, calculous pyelitis, cysts, hydronephrosis, tumors, and fistulæ connected with the ureters *so soon as the life of the patient is endangered, and when other methods have proved ineffectual.* This, too, only provided the other kidney is healthy.

He advises nephrectomy by the abdominal incision when the kidney is movable; by the lumbar incision when it is fixed, and regards the lumbar incision as the safer operation.

Ultzmann,[4] after speaking unfavorably of the plan of total extirpation of the kidney, and of the treatment by puncture and the injection of iodine, says "the most advantageous method is, however, incision of the tumor, especially when done in Simon's method." This consisted in inserting four little trocars into the sac so that they inclosed between them a diamond-shaped space upon the abdominal wall. These were left in place some time in order that the slight inflammation caused by their presence might bring about an adhesion of the peritoneal surfaces; finally, an incision was made through the middle of the space inclosed by them, and the sac opened.

Kroner,[5] in the course of an article upon the surgery of the kidney, discusses the treatment of hydronephrosis by incision and drainage. He only succeeded in finding five reported cases, three of which proved fatal. He comes to the conclusion that it is impossible to secure the obliteration of the hydronephrotic sac.

[5] Archiv f. Gynækol., 1881, xvii., p. 87.

If there be any bit of secreting tissue left this will, on relief from pressure, go on secreting urine. To find the orifice of the ureter and restore its potency is so difficult as to be practically impossible. Injection of the sac with iodine is fruitless.

Weir [1] has had two cases which he successfully treated and cured by antiseptic incision and drainage. Both of these patients were young men. In each of them a bougie was passed from the wound into the ureter until it met an obstruction, and was then found to be firmly grasped as by a stricture.

Peters [2] has operated upon one case in a woman of forty-seven. In this case a sinus remained at the end of a year, which, however, discharged but little. Antiseptic precautions were omitted after a few dressings.

Tuckwell [3] has reported a case in which he operated in a similar manner upon a child eleven years old, with congenital hydronephrosis. He obtained a perfect cure.

M. Le Dentu opened a hydronephrotic sac in the groin, but was later obliged to remove the organ by lumbar incision. His patient recovered.

The case reported at the head of this paper together with those which I have quoted above seem to indicate that in some cases at least the simple incision and drainage of the cyst is competent to work a cure.

By making the opening in the lumbar region the danger of peritonitis, against which Simon's method imperfectly guards, is avoided. The thinness of the cyst wall in my case would have made it a matter of considerable difficulty to keep the urine out of the peritoneal cavity had the operation of nephrectomy been attempted, and the restoration of the functions of the kidney shows that that operation would have unnecessarily removed a useful organ.

The fact that a hydronephrosis had a traumatic origin should, I think, encourage us to hope that by simply emptying the cyst, and giving the constricted portion of the ureter a complete rest from pressure a cure may be accomplished, and the calibre of the ureter may be restored.

Two of the cases of cure by aspiration which I have reported, as well as my case, were consequent upon an injury.

The immediate local effects of an injury (inflammation or hæmorrhage) may pass off, and yet the hydronephrosis once established persists. Something may be learned in this regard from the behavior of the urethra under somewhat similar circumstances.

A moderate stricture of the urethra or an enlarged prostate may allow a sufficiently free passage of urine. An occasion arises when an accident of circumstance prevents the passage of urine when the bladder is full and it becomes over-distended; complete retention is the result. This is a not uncommon experience, and that the urethra becomes again pervious when, by aspiration or puncture, the urine is drawn off and the pressure relieved is well known.

We should, therefore, I think, in hydronephrosis of recent origin, particularly when it depends on traumatic causes, expect that in a fair proportion of cases, after aspiration or incision in the loin, the relief from pressure will allow the ureter to recover its calibre.

If aspiration is not followed by high fever or other unpleasant symptoms it may be repeated a number of times. One case of recovery after eight aspirations is reported. When, however, as in the case which I have reported, the aspirations are followed by considerable fever, when the cyst rapidly refills, and the patient loses rather than gains ground, an antiseptic incision is, I think, called for.

SOME TYPHOID EPIDEMICS OF THE PAST DECADE, AND THE NECESSITY OF COMPULSORY DISINFECTION.[4]

BY MORTON PRINCE, M. D.,
Assistant City Physician, Boston.

MY object in presenting this paper to your notice is to advocate the adoption of measures which I believe offer a fair promise of diminishing the frequency of typhoid fever, and especially of preventing the occurrence in the future of those widespread epidemics which have proved so disastrous to whole communities in the past. These measures are nothing new; they are familiar to us all. It is to the necessity of their rigid employment that I wish to call attention; "an ounce of prevention is worth a pound of cure," and if there be any practicable means at our command, which holds out any reasonable promise of diminishing the number of cases of typhoid fever in any appreciable degree, it is not only our duty to employ it, but I believe it to be the duty of the government to see that it is employed. Whether there is reason to believe that we have such a means I propose now to consider.

As every one knows, there are two theories as to the origin of typhoid. The one, originally proposed by Budd, maintains that the active principle of typhoid fever is a specific poison, which can only arise from a preceding case of the fever, and never *de novo*. No matter how much filth may be introduced into the system, it can never give rise to typhoid, unless the specific poison be present in addition. As Leibermeister puts it, no matter how well you manure your fields, unless you sow the seed you cannot reap one beard of wheat, and this poison (germs, if you will,) of typhoid, like the grains of wheat, though it may require a soil of decomposing, organic matter for its growth, can never itself be produced by anything but preëxisting typhoid poison.

According to the second theory, although the poison, which has been introduced into the system, *may be* transmitted from some preceding case, it also may arise spontaneously or *de novo* from decomposing, organic matter.

Now it will be noticed that there is one thing common to both theories, and that is, that typhoid fever may be produced by the poison generated in one case being introduced (though possibly only after having undergone secondary transformation) into the system of another. In other words, it is *possible* for one case to infect more or less directly another case.

However strong may be the evidence in favor of the spontaneous origin of typhoid, the evidence is equally strong in favor of its being transmitted from one person to another *under certain conditions*. These conditions require the poison contained in the intestinal discharges to be introduced into the system by one way or another, as, for example, by water, by air or milk. There are those who hold that typhoid can only arise by infection from a preceding case in this way. This,

[4] Read December 17th before the Suffolk District Medical Society.

I think, must be considered at present unproven. Though the possibility of its being true must be admitted. It is a question, however, which is beyond my purpose to consider here, as I propose to deal only with reasonably well-established facts; and one of these facts is that typhoid can be transmitted from one person to another, though perhaps indirectly. The occurrence of outbreaks of this fever has been too often associated with the pollution of drinking water and of milk, with the intestinal discharges of previous cases, to allow of explanation through the theory of mere coincidence. So far as we know, the only way by which the contagium is conveyed is by means of the intestinal discharges. The practical question for us, as sanitarians, is, How often is the poison transmitted in this manner? How many cases can be shown to have been infected by preceding cases? For if the number be small, no prophylactic measures looking to disinfection as a remedy will be of benefit; if the number be large, we shall be justified in employing such means as will insure us against the dangers of contagion. It stands to reason that whatever cases are annually caused in this way would not occur if the poison were thoroughly destroyed when generated in every case; and if the number be considerable it would clearly become the duty of the government, municipal or State, to see that this precaution is taken. Now what are the data which can be utilized for this purpose?

Unfortunately we are met with difficulties at the very beginning. Not only is it impossible to trace endemic cases in most instances to their sources, but even when this is attempted and successfully done, the results are rarely published; and especially is this the case in large towns, where the surrounding conditions are most complex, and a different focus of infection exists for nearly every case. The time and labor requisite for the investigation of such cases would be so great as to render any such attempt impracticable.

It is only when the number occurring in any one locality reaches such proportions as to constitute an epidemic and to cause alarm that attention is attracted to the danger and thorough investigation is made. It is often then found that a large number, if not all, the cases can be traced to one focus of infection. Accordingly it is only such instances which can serve us in solving the problem we have undertaken. But it may be safely concluded that the same law holds good for the one class of cases as for the other, and if the instances shall be found to be numerous where epidemic cases are due to infection from a preceding case, it may be concluded that endemic cases of similar origin are of equal frequency, to say nothing of the danger to which communities are exposed from epidemics.

In searching the medical literature for data I have confined myself principally to English sources for several reasons.

In the first place, for the proper investigation of the causation of disease there is required suitable sanitary machinery, such as does not obtain in this country, but is to be found in England, where every district, I believe, has its health officer or expert medical inspectors. The reports of these officers are always published, and consequently the results easily obtained. Then, again, widespread epidemics are not as frequent in this country as in England, if one can judge from the little information at hand. On this we are to be congratulated, but no one knows how long this immunity, if it is an immunity, will last. Information on the occurrence of epidemics with us is too scanty, and difficult of access for use. In English literature we have an *embarras de richesse*. When, however, I have accidentally come across an account of an epidemic occurring elsewhere I have occasionally noted it. The list is a long one, and the time at my disposal will allow me to give in detail only a few of the most noted epidemics. These will serve as examples of the manner in which typhoid may be propagated.

The first I have to relate is an exception, and did not occur in England, but it is so striking in its details and in the skillful manner in which it was investigated that I cannot forbear to relate it.

CASE I. In the summer of 1872, in the neighborhood of the little Swiss village of Lansen, consisting of only seven hundred and eighty inhabitants, there occurred in a farm-house, situated about a mile from the town, and separated from it by a mountain, a case of typhoid fever. This case was followed by three others in the same house. The physician in charge directed that the discharges be disinfected and buried. This warning was heedlessly neglected, and they were thrown into the privy and upon a dunghill without disinfection. As a result the poison was washed into a brook which helped feed, by a subterranean passage running under the mountain, the spring supplying the town. An epidemic broke out, and within the first three weeks one hundred of the inhabitants were attacked. Before it ceased 137 persons fell ill, or seventeen per cent. of the population.

CASE II. In 1879 the water supply of Caterham and the neighboring district proved insufficient, and the water company sank a new well, and constructed an adit leading from this to one of the old wells. It happened that one of the workmen employed in the excavations suffered from typhoid fever, but continued work for a while, though troubled with profuse diarrhœa. This man frequently polluted the well with his discharges, and as a consequence the poison was carried into the water mains, and an epidemic of typhoid broke out amongst those using the company's water. In six weeks 350 people contracted the disease. Before the epidemic ceased this number was raised to 370.

I now proceed to relate some examples of another source of infection, namely, milk: —

CASE III. In a district of London called Marylebone, in the summer of 1873, there broke out an epidemic of typhoid fever. Two hundred and forty-four cases occurred in one hundred and forty-three households. On investigation it was found that two hundred and eighteen or nine tenths of these were in families which obtained their milk from the same dairy. But, on the other hand, in sixty-three families supplied by this dairy there were no cases of fever. Further investigation showed that all the families in which the fever appeared used a particular or nursery milk, while not one of the sixty-three families used it. It was further ascertained that this dairy from which the suspected milk came was supplied by seven farms, and from the seventh the nursery milk came. Inquiry at this farm revealed the following facts: A short time previous to the outbreak the occupier fell sick with typhoid fever, and died. His discharges were not disinfected, but in order to guard against contagion they were carried away, and buried in an ash heap beyond the precincts of the farm buildings. It turned out to have been the most unfortunate spot that could have been chosen. The water used for *dairy* purposes had been drawn from a well situated in a yard adjoining the farm-house. This had been given up for drinking purposes on account of its bad taste. It was then shown that the soakage from a certain pig-sty had made its way towards the well along the foundation of a wall. Against this very wall stood the ash heap in which the enteric stools and slops had been buried. Thus the typhoid poison had been introduced into the milk, and 244 persons were infected.

I come now to record a famous epidemic which is strikingly interesting both from the directness with which the source was discovered, and from the virulence of the epidemic itself: —

CASE IV. In the town of Over-Darwen, England, in a house at a considerable distance from the town itself, there arrived a young woman suffering from typhoid fever. The drain from this house emptied itself into a neighboring field for agricultural purposes. Unfortunately, through this field passed the water main carrying the water for the town. Special precautions had been taken

to avert the danger of sewage percolating through into the water. In spite of this, however, it was afterwards found that where the drain and water pipes came in contact there was a leak, which allowed the contents of the drain to be sucked freely into the water pipe. The sequence of events was as might have been anticipated. The dejecta of the first case were thrown without disinfection into the water-closet; from here they passed into the house drain, and entered the water main, which in turn distributed the poison amongst the inhabitants of the town. In three weeks from the arrival of the first young lady a terrible epidemic broke out, and 2035 persons were attacked.

Although I might add to this list the stories of many more epidemics, I will not task your patience with telling them. Those I have just related are but a few of the many I have collected. I have here a long list of many more, all occurring within the past few years, and traced to the pollution of either milk or drinking water with the poison in the discharges of typhoid patients, and by which 7148 persons were attacked. In this number I have not included the epidemics of North Taunton, of Arcot, of Basle, of Baldock, of Beddle, of Bradford, of Dewesbury, of Guildford, of Hucknall Torquard, of Lewes, of Sherborne, of Terling, of Tideswell, of Crosshills, of Dublin, of Tolcarne Head, of Swansea, and of Croydon (1878), and Shrewsbury, by which many thousands more were attacked, because, though distinctly traced to the pollution of water or milk, it was not, in my opinion, shown conclusively that the poison of typhoidal discharges was also present. Nor have the large number of smaller epidemics been included, even though traced to specific infection, because of the labor necessary for the research.

The epidemics which have been utilized were all, or nearly all, investigated by official inspectors, sanitary experts of the highest skill, and by them reported on. As a result we have a total of seven thousand one hundred and forty-eight cases in which it was distinctly determined that the poison had been transmitted from the intestinal discharges of a previous case. Seven thousand cases which might have been prevented had proper precautions been taken.

There can be no doubt that the little town of Lansen would have been spared the terrible catastrophe which overtook it were it not for the carelessness and indifference of the people who failed to obey the directions of the physician attending the first case.

Had the intestinal discharges of the farmer, who supplied the dairy at Marylebone with milk, been disinfected before being disposed of in the ash heap, that town would have escaped the disaster which befel it.

Had proper precautions been taken in disposing of the excreta of the young woman who carried the fever to Over-Darwen, two thousand inhabitants of that unhappy town would have been spared.

The same story is repeated over and over again. It was repeated in Lower Gornae, where seven hundred persons were infected from poisoned privies and wells, and in Glasgow in 1873, and again in 1878 and 1880, where nearly four hundred caught the fever from polluted milk. It was repeated in Hawkesbury Upton, where one hundred and thirteen persons out of six hundred inhabitants contracted the fever by drinking water which had been infected with the discharges of a man, who arrived in the village while sick with the fever, and in the little settlement of North Boston, where over half the population fell sick within a month after the arrival of a stranger ill with the disease. It has just been repeated in the pollution of the water supply of Bangor, England, and the outbreak of an epidemic which only ceased during this last month, and which attacked five hundred and forty-eight persons. It was repeated everywhere else.

How little the mere numerical figures tell us of the real suffering inflicted. How little they tell us of the long days and nights of lingering pain, of the anxious watchings, the midnight vigils, the alternate hopes and fears, and the vacant hearths. How little of all this can be told with numbers. This can only be known by those who have suffered.

(To be continued.)

RECENT PROGRESS IN MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M. D.

TOXICOLOGY.

DISTRIBUTION AND ELIMINATION OF LEAD.

Victor Lehmann [1] has reached the following conclusions as the results of experiments made upon rabbits to whom varying amounts of nitrate of lead had been administered subcutaneously. The amount of lead in the organs and secretions is dependent only to a certain extent upon the amount introduced into the system.

The greatest amount is found in the bile, heart, and kidneys; after long-continued administration the amount in the brain and bones becomes considerable.

The liver, muscles, and blood invariably contain a smaller quantity than the remaining organs and secretions. In one case 0.250 grammes of nitrate of lead was administered; the amount of lead extracted from three grammes of bile exceeded slightly the amount extracted from thirty-two grammes of liver.

Elimination takes place through the urine and bile about equally. Lead could not be detected in the urine sixteen days after the administration of 0.5 grammes of nitrate of lead. If, twenty-four to thirty days after poisoning, and when lead could no longer be detected in the urine, iodide or bromide of potassium was administered to the amount of fifty milligrammes daily, lead again appeared in the urine in appreciable quantity. An equal amount of chloride of sodium had no influence on the elimination.

THE ACTIVE POISON IN THE COMBUSTION-PRODUCTS OF TOBACCO.

R. Kissling [2] has collected the principal publications on this subject, and the present paper is devoted to a critical discussion of the same, and at the same time to an account of his own investigations.

Referring to Melsens' researches the author mentions that he is the only investigator who has conclusively established the existence of nicotine in tobacco-smoke. The quantity of this alkaloid amounts to about 0.7 per cent. of the weight of tobacco consumed, and about fifteen per cent. of the total quantity of nicotine contained in tobacco. He shows that Vohl's opinion as to the non-existence of nicotine in tobacco-smoke is without foundation. Vohl evidently disregarded the fact that nicotine is decomposed by warm potassic hydrate. The publications of Heubel, LeBon, and Pease, who found nicotine in tobacco-smoke, cannot be regarded as a satisfactory solution of the whole question, as they are very incomplete.

[1] Berichte der deutschen chemischen Gesellschaft, 1882, page 2627, from Zeitschrift für physiologische Chemie, vi., p. 528.

[2] Journal of the Chemical Society, London, 1882, pages 906 and 1253, from Dingler's polytechnisches Journal, 1882.

The author's investigations were made mainly with a view of proving the presence of nicotine. His experiments were made with cigar-smoke, as this is the form in which tobacco is most extensively consumed. The smoke of a cigar was drawn, by means of an aspirator, through a long condensing tube and a system of five flasks. The first and third flasks were empty, the second contained alcohol, the fourth dilute sulphuric acid, and the fifth weak soda-lye. The current of air, and with it the intensity of smoking, was regulated so that a cigar lasted for about half an hour. The ingredients condensed and absorbed in the various flasks were then examined. Full details are given of the various experiments and of the methods of examination employed, and the results are arranged in a series of tables.

The conclusions arrived at by the author are the following: Carbonic oxide, sulphuretted hydrogen, hydrocyanic acid, the picoline bases, and nicotine are the active poisons contained in tobacco-smoke. The quantity of the first three constituents is too small and their volatility too great to be of importance in determining the influence of smoking on the organism. The picoline bases also are present in relatively small quantities, so that the toxic action of the smoke is essentially due to the large proportion of nicotine contained therein. As the cigar becomes shorter the smoke becomes richer in nicotine. The proportion of nicotine destroyed by smoking a cigar is relatively small.

POTASSIO-BISMUTHOUS IODIDE AS A TEST FOR ALKALOIDS.

F. Mangini[1] finds that the characters of this reagent vary considerably according to the manner in which it is prepared. When obtained by Russland's process, described by Dragendorff, it produces a turbidity even in pure water; but when prepared by mixing three parts of iodide of potassium with sixteen parts of liquid iodide of bismuth and three parts of hydrochloric acid, it does not give any turbidity with water, and is an extremely delicate test for alkaloids, serving also to distinguish many of them one from the other by the various gradations of color of the precipitates and their alterations after long standing. The behavior of the more important alkaloids with this reagent is described in the original paper.

URINARY CHEMISTRY.

REDUCING SUBSTANCES IN THE URINE.

W. G. Smith, M. D., in a paper read before the Dublin Biological Club, April 18, 1882,[2] reports a case in which the urine presented all the characteristics of a urine described by Boedeker in 1861, that is, it contained a reducing substance, with a strong affinity for oxygen. Boedeker gave the name alkapton to this substance. The urine in the case reported by Dr. Smith was passed by a girl three years old, apparently in perfect health, and not taking any medicine. It was normal in appearance when first passed, but on being allowed to stand it deepened in color, and stained the child's linen. Its specific gravity was 1025, its reaction acid. Bile and albumen absent. Urea = 1.2 per cent. The urine gave the reactions of the so-called alkapton. Ferric chloride produced a distinct green color, which was turned reddish brown by the subsequent addition of an alkali.

It is probable that the word alkapton can no longer be considered as referring to any definite substance. If retained it must be regarded rather as a general term including several bodies which confer upon urine the property of becoming dark with an alkali, from above downward. In Ebstein and Müller's case[3] it appears probable that the alkapton reaction was due to brenzcatechin, which is known also by the name pyrocatechin.

In Dr. Smith's case the reducing substance was precipitated by the basic acetate of lead. The precipitate was washed, diffused in water, and decomposed by sulphuretted hydrogen; the sulphide of lead was separated by filtration, and the filtrate distilled in an atmosphere of carbonic-acid gas. The reducing body remained in the residue. From the fact that it did not volatilize on distillation, and on account of the characteristic reaction with ferric chloride, which was obtained both from the original urine and from the residue after distillation, Dr. Smith concludes that the body which gave the reactions was protocatechuic acid. An optical examination made subsequently by Professor Hartley confirmed this conclusion.[4]

From the researches of M. Vetlesen, published in *Nordiskt Medicinskt Arkiv* for 1882,[5] it appears that during the internal use of oil of turpentine the urine contains a rather large quantity of a reducing substance, which, on boiling, reduces an alkaline solution of oxide of bismuth, and reduces the black oxide of copper, and seems by its reactions to be composed in great part of matter strongly resembling grape sugar without being in any way identical with it. The reaction disappears after fermentation, which process appears to act more slowly than with grape sugar. A small quantity of hydrochloric acid destroys this reducing substance at a relatively low temperature, while grape sugar is only slightly destroyed. It appears to be optically indifferent. The body is probably a kind of fermentable sugar, the nature of which is not exactly determined. Its quantity seems to be related to the amount of the dose of turpentine, and diminishes if the use of this drug is continued for a certain time.

A VARIETY OF ALBUMEN COAGULATED BY NITRIC ACID AND REDISSOLVED BY ALCOHOL.

The most common test for albumen in the urine is the nitric-acid test. After the internal use of turpentine or balsams the urine at times contains resinous matters which are precipitated by nitric acid as a white cloud, which is redissolved on the addition of alcohol, and is thus distinguished from albumen. L. Garnier[6] calls attention to two cases of nephritis in which the urine treated with nitric acid gave a coagulum soluble in alcohol; the patients, however, had taken no turpentine or balsams. Further study showed that these urines contained a variety of albumen which was coagulated by boiling, by picric acid, and by alcohol; which reacted to Millon's reagent; which was coagulated by nitric acid; the nitric acid coagulum was, however, soluble in alcohol, and might have been mistaken for resinous matters, if its reactions had not been further studied. The amount of

albumen in the twenty-four hours' urine was in one case three and one half grammes, in the other case two grammes.

COMMON SALT AS A TEST FOR ALBUMEN.

Dr. William Roberts[1] recommends a saturated solution of salt, acidulated with about five per cent. of the dilute hydrochloric acid of the Pharmacopœia, as a very delicate test for albumen. The method of applying the test is similar to that employed with nitric acid. The salt solution is allowed to flow down so as to form a distinct layer below the urine. If albumen is present a white cloudy zone appears at the junction of the two fluids. The precipitation of albumen by an acidulated salt solution is not due to a true coagulation. In this respect the salt test differs from the nitric acid and heat tests. In the latter cases the albumen is transformed into an insoluble modification, coagulated albumen. In the salt test the precipitate is not insoluble, but is redissolved by the free addition of water, or even by the free addition of the albuminous urine itself. It is therefore essential that the salt solution should be in excess at the point of the expected reaction. In point of delicacy the salt test equals the nitric acid test. In high-colored urines it is superior, as it does not produce any deepening of the tint as nitric acid does, neither does it disengage any gas. It causes no precipitation of urates. Like nitric acid it produces a cloudiness in the urine of patients taking large doses of resinous substances, and it produces this reaction whether the liquid is hot or cold. The cloudiness caused by resinous substances is not removed by the addition of more urine. Another advantage of the salt solution is its non-corrosive character. A serious disadvantage is that it precipitates peptones, so that a slight cloudiness may occasionally be obtained in urines with which the nitric acid and heat tests give no reaction. Dr. Roberts thinks a better idea of the quantity of albumen present, as indicated by the density of the cloud, is obtained by the nitric-acid test.

NEW URINARY COLORING MATTERS.

Three new urinary coloring matters have been observed. P. Plósz[2] met with one in the urine of a patient suffering from cysto-pyelitis with chronic parenchymatous nephritis. The urine, upon exposure to the air, assumed first a greenish-brown, after longer standing a reddish, color on the surface. The sediment contained a reddish-violet coloring matter, crystallizing in sheaf-like collections of needles or rhombic plates; it was soluble in ether or chloroform; its solution showed two well-marked absorption bands, one between D and E, but nearer D, the other between b and F, but nearer F. The coloring matter was not changed by exposure to air, warming, by acids, or alkalies. The author suggests that it may be a scatol derivative, analogous to indigo-blue. It was again met with in the urine of a patient suffering with chronic peritonitis with effusion into the abdominal cavity.

M. Nencki and N. Sieber[3] have obtained from urine a new coloring matter for which they propose the name uroroseïn. It was first obtained by them from the urine of a patient suffering from a severe form of diabetes mellitus. In four other cases of the same disease the coloring matter was absent. They have met with it in the urine in other diseases; in all, in about ten per cent. of the pathological urines examined by them. They have never found it in the urine of persons in health. It may be detected as follows: five to ten cubic centimetres of a twenty-five per cent. solution of sulphuric or hydrochloric acid are added to 50–100 cubic centimetres of urine. If uroroseïn is present the urine assumes a reddish color; the urine is then gently shaken with a few cubic centimetres of amylic alcohol, which takes out the coloring matter. The red alcoholic solution shows a characteristic absorption band between D and E, but somewhat nearer D. The color appears to exist in the urine in the form of a sulpho-acid, the salts of which are decomposed by mineral acids in the cold. It is not removed from urine by common ether, chloroform, benzol, or bisulphide of carbon; it is, with difficulty, soluble in acetic ether; ammonia, the fixed alkalies, and alkaline carbonates immediately decolorize the red solution obtained by the addition of acids to the urine, but the color returns upon the addition of an acid in excess. Its acid alcoholic solution is immediately decolorized by zinc dust; if, however, the filtered liquid is exposed to the air it soon assumes again the red color. The coloring matter is very unstable, and this fact, the authors think, explains its non-observance hitherto in pathological urines. Uroroseïn differs distinctly from urobilin and indigo-blue, and from all coloring matters hitherto found in pathological urines. It resembles closely the rosaniline colors, but differs from them in being very unstable.

E. Neusser[4] has observed a new pathological coloring matter in the urine of a patient suffering from pleuritis. The urine had a blood-red color, an acid reaction, and contained no albumen. Examined spectroscopically it showed two sharply defined absorption bands between D and E, occupying the position of the oxy-hæmoglobin bands; also a tolerably strong darkening of the violet end of the spectrum up to the line b. The spectrum was not changed by the addition of sulphide of ammonium or by boiling with potassic hydrate. If the urine was boiled with hydrochloric acid and then decomposed with potassic hydrate, the coloring matter was carried down with the phosphates and could be removed from the precipitate by means of alcohol acidulated with sulphuric acid. It could also be extracted from the evaporated urine by means of alcohol containing oxalic acid, but not by ether or non-acidulated alcohol.

The urine did not respond to the turpentine and guiacum test. Tannin gave a dirty-red precipitate, from which no hæmin crystals could be obtained. It was not satisfactorily determined whether or not the coloring matter contained iron. The acid alcoholic solution was decolorized by zinc and hydrochloric acid, as well as by sodium amalgam. From the spectroscopical appearances, which are minutely described in the original paper, Neusser concludes that the coloring matter is either hæmatoporphyrin or a body very similar to it. He met with the coloring matter a second time in an albuminous urine of a patient with tuberculosis.

ACETO-ACETIC ACID. ACETONURIA.

Jaksch[5] believes he has isolated the substance which

[1] The Lancet, October 14, 1882, page 613.
[2] Zeitschrift für physiologische Chemie, vi., p. 504.
[3] Journal für praktische Chemie, 1882, Nos. 17, 18, page 333.
[4] Zeitschrift für analytische Chemie, 1882, page 476. Abstract.
[5] Berichte der deutschen chemischen Gesellschaft, 1882, page 1496.

in many urines causes a red color upon the addition of ferric chloride. He finds that it is an acid, soluble in water, alcohol, and ether. It forms salts with the bases. He has as yet obtained none of these in the crystalline form. The acid, which in his opinion is aceto-acetic acid, as well as its salts, even when in minute quantity, gives a red color upon the addition of ferric chloride. They are decomposed, upon warming, with the production of acetone.

Jaksch has also examined[1] the urine in nearly six hundred cases of various acute and chronic diseases, and finds that the reaction in question may occur not only in the urine in diabetes mellitus, but also in that of the acute exanthemata and other affections. He also finds that the substance producing the reaction may be distinguished in two ways from other substances, as formiates, acetates, phenol, salicylic acid, and sulphocyanic acid, which give a similar color with ferric chloride.

(1.) It is decomposed by heat; if, therefore, the urine is boiled for five or six minutes the reaction can no longer be obtained.

(2.) It may be removed from the urine by shaking the latter with ether, and may be detected in the ether solution by the addition of ferric chloride; the red color thus obtained fades upon standing for some days.

The red color produced by the substances previously mentioned is stable; if due to formiates or acetates the color disappears upon boiling, and a basic salt of iron is precipitated; salicylic acid may be removed by shaking the urine with benzol or chloroform, which do not remove aceto-acetic acid.

Jaksch also believes[2] that the volatile substance which, according to Lieben,[3] is contained in the distillate from normal urine, and from which iodoform is obtained by the action of sodic or potassic hydrate and iodine, is acetone, which must therefore be considered a constant and normal product of tissue metamorphosis.

The amount of acetone in the daily urine of a person in health is probably not more than 0.010 gramme. An increased amount is at times found in the urine in diabetes mellitus, especially in those cases in which the urine gives the red color with ferric chloride. But the author has also found that the distillate from febrile urines contains with great regularity and in relatively large quantity a substance which gives the iodoform reaction. This substance was obtained from three hundred litres of febrile urine, and was separated by fractional distillation into two bodies, one of which came over at 55.8° C., the other at 73°–76° C. The first was identical in all its properties with acetone, the second with alcohol, containing traces of acetone. From three hundred litres of urine 6.3 grammes acetone and 2.2 grammes alcohol were obtained. The quantity of acetone in febrile urine is, as a rule, several decigrammes, and increases as the fever increases. In non-febrile affections the amount of acetone excreted is not, as a rule, increased. Exceptions were observed, however, in some cases of carcinoma, in hydrophobia, in the so-called acetonæmia, and in certain cases of diabetes mellitus. In increased acetonuria the urine at times, but by no means always, gives the reaction for aceto-acetic acid.

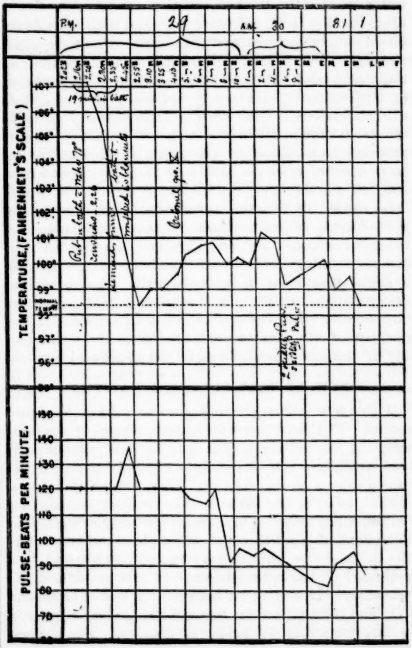
Hospital Practice and Clinical Memoranda.



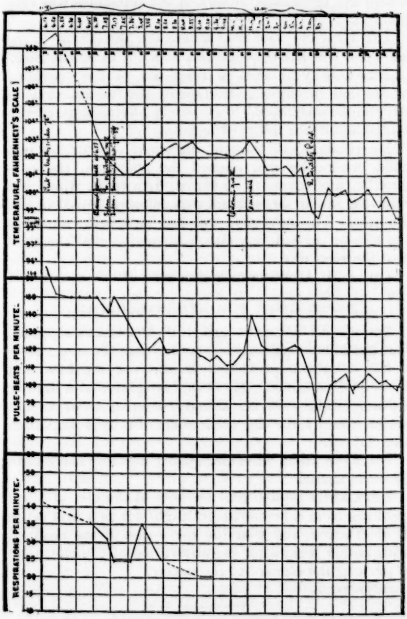
BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF A. M. SUMNER, M. D.

REPORTED BY DR. MAURICE D. CLARKE, HOUSE PHYSICIAN.

TWO CASES OF SUNSTROKE. RECOVERY.

——— ———, a single man, thirty-three years old, a native of Ireland, a waiter at the Parker House was brought to the hospital July 29th (an excessively hot day) by the police, who could give no information about him. He was unconscious; his pupils were slightly unequal, contracted, and irresponsive to light; his breathing labored; an odor of alcohol was detected in his breath; his temperature, by the rectum, was 107.2° F.; pulse 120, of fair strength.



The diagnosis of sunstroke was made, and the patient was placed in a bath of 78° F., and an ice-bag applied to his head. In ten minutes he was able to tell his name and answer questions. At the end of fourteen minutes the temperature had fallen nearly two degrees, and five minutes later it was 102.7° F., when he was taken out of the bath, placed on a bed, and covered with blankets. The temperature, however, continued to fall until, twenty minutes later, it reached 98.6° F. The pulse remained at 120 till evening, when it fell to 92. There was a secondary rise of temperature (101° F.) in the night, and a fall to normal

the next morning. Physical examination, later, discovered a general bronchitis and chronic catarrhal pneumonia at one apex. He had no other symptom or sign, and was discharged the next day.

—— ——, a widower, sixty-eight years old, a native of Ireland, without any occupation, was found unconscious in a barn the afternoon of August 9, 1882, and taken to the hospital two hours later, still unconscious (Dr. E. J. Forster on duty). Temperature by rectum 108.4° F.; pulse 168, of fair strength; respirations 42; pupils alike, contracted, and irresponsive to light. He had had involuntary dejections. He was put at once in a bath at 78° F., and an ice-bag placed on his head.

Five minutes later the temperature had risen to 108.8° F., and the pulse was 152. The breathing was irregular, sometimes stopping altogether for a second or two. The pupils began to dilate.

Twenty-five minutes later the temperature had fallen to 104.7° F.; pulse 150; respirations 36. Parts of

the body turned bluish, and friction was applied smartly with the hands and with a flesh-brush.

After being in the bath thirty-eight minutes he was taken out, the temperature then being 103.4° F. and the pulse 150. The heart's action was quite feeble, and ten minims of tincture of digitalis and ten grains and a half of ammonium carbonate were given by hypodermic injection. He was left naked on the bed to still farther cool.

Thirteen minutes afterwards the temperature was 102° F.; pulse 141. Nine minutes later he vomited and had an involuntary dejection. Fourteen minutes later the temperature was 101.5° F.; pulse 150; respirations 24. He was covered with blankets and surrounded with heaters.

After the lapse of eighteen minutes the temperature fell to 101° F., which was the lowest point it reached until the next morning. The pulse was 132. There was another involuntary dejection. Ten minutes later the temperature had risen to 101.6° F., but the pulse had fallen to 120. The pupils were dilated but responsive, and other reflexes were present.

For the next hour and a quarter the temperature was over 102° F., reaching 102.8° F. once, but the pulse continued to fall. The blankets were removed, and he was given several sponge baths. There was another involuntary dejection and several slight attacks of vomiting.

Four hours and a quarter after being put into the bath his temperature was 102° F., pulse 112, and he was semi-conscious, but it was not until an hour and three quarters later that consciousness fully returned. There were no unfavorable symptoms during the night, but it was not until the next morning that his temperature reached normal. There was a slight secondary rise (99.4° F.) during the day.

Physical examination showed some pulmonary emphysema and chronic bronchitis, a heart somewhat dilated, with mitral insufficiency, pulmonary œdema, and atheromatous arteries. He remained in the hospital three weeks, during which time the heart's action became more regular, the œdema disappeared from the lungs, and the general physical condition improved. His mind, however, showed signs of decay, he never seeming fully to realize his surroundings, and being subject to delusions about his friends and himself. This condition may have existed before the sunstroke. The day after the attack there was albuminuria, but this disappeared before he was discharged.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

SURGICAL SECTION.

H. C. HAVEN, M. D., SECRETARY.

JANUARY 3, 1883. DR. R. M. HODGES in the chair.

DR. H. B. BOWDITCH exhibited Professor Bell's

INDUCTION BALANCE AND ELECTRIC PROBE FOR BULLETS,

and, assisted by Mr. Gleeson, demonstrated its action. A needle, buried in the thigh of a patient of Dr. A. T. Cabot, was accurately located; its position had been previously ascertained by Dr. Cabot, and its correct location by the instrument was subsequently demonstrated to those present.[1]

On motion of Dr. H. I. BOWDITCH, the thanks of the Section were voted to Professor Bell and Mr. Gleeson.

DR. J. COLLINS WARREN reported.

TWO CASES OF COLOTOMY.

DR. JOHN HOMANS, in opening the discussion, spoke as follows: I consider colotomy one of the most benefi-

[1] For full description of the instrument and Dr. Bowditch's remarks see the Proceedings of the Boston Society of Medical Sciences, to be hereafter published.

[2] See page 172 of this number of the JOURNAL.

cent of now curative operations, the relief afforded being very great.

This operation is very popular in England. There is a great difference in the amount of distention of the abdomen in intestinal obstruction. Some patients go four or five weeks without much distention.

I saw one case where there had been no movement of the bowels for two months, the skin was brown, and the sweat had a fæcal odor; it is now a year, and I am *told* there has been no movement. The first time I operated I had never seen it done; this case was reported in the Boston Medical and Surgical Journal. The woman was a patient of Dr. Cutler's. There was temporary obstruction of the rectum following confinement six weeks previously. There had been no dejection for three weeks, and the vomiting was stercoraceous. Allingham's method was employed. The patient recovered, and the rectum became patent. She went to New York, and I afterwards heard of her through the late Dr. Erskine Mason, who had tried to close the small fistula which was left, but without success.

In the second case I removed an ovarian tumor from a woman in 1881. Some time after constipation was noticed, which gradually increased until not even flatus was passed. I thought at first that the operation was responsible for it. I opened the abdomen through the cicatrix, and found nodules of cancer. Upon separating the intestine from the cicatrix no obstruction was evident, but an annular stricture was finally discovered at the upper end of the sigmoid flexure. I did not try to excise it, as I could not get it above the mons veneris. Dr. Elliot held the bowel while I made an incision into it and stitched it to the edges of the skin just over the pubes. A great gush of fæces followed, and I think that a little got into the abdominal cavity. She recovered entirely, and got through the following summer very comfortably. Her only difficulty was that she could not control the passage of wind. She died about a week ago, and at that time there was a mass of cancer extending from the left inguinal region up to the liver. My next case was that of a woman from the West with intestinal obstruction. She was a patient of Dr. Nichols. I made my incision on the right of the rectus into the peritoneal cavity, and on exploration found obstruction in the descending colon near the lower splenic region. It was very difficult to return the coils of intestines through the incision before opening the colon, and this is the difficulty which is usually met with in these anterior peritoneal operations. I finally succeeded in reducing the bowels; opened the colon and stitched the edges to the edges of the incision. Great relief followed, but the final result was fatal. The discomfort which follows this operation is not as great as would be supposed. A pad is worn over the artificial anus, which is removed at regular periods, and the fæces are received into some conveniently-shaped cup. I consider the lumbar operation the best, although it is difficult to decide often whether to operate on the right or left loin. The operation relieves the patient from a great deal of suffering, and the after condition is not as nasty as is commonly imagined.

In reply to a question by Dr. Lyman, as to whether contraction of the opening followed, Dr. Homans replied in the negative, and that in the lumbar region there was even a tendency to prolapse.

For the first few days there was apt to be a considerable discharge of mucus.

DR. GANNETT asked if there was any desire for defecation in these cases?

DR. HOMANS had not met with it. In one of his cases fæces were sometimes formed in the rectum, and had to be dug out at intervals.

DR. WARREN stated that one of his patients did have a sensation of desire to defecate. It was stated that if the opening was small it had a tendency to close.

DR. H. P. BOWDITCH asked Dr. Homans where the fæces present in the rectum, as mentioned by him, came from, and whether they might not have been there before the operation?

DR. HOMANS thought there might have been a private passage through which the liquid parts of the fæces passed and afterwards became solid.

DR. MIXTER said that he had seen Mr. Heath operate in London, and that he had been obliged to puncture the bowel to relieve the distention before being able to return it.

DR. LYMAN spoke of a case under his observation, where the vermicular motion of the intestines was very marked.

DR. HOMANS said that where the distention of the abdomen was not extreme this was apt to be the case.

DR. CHEEVER said, in reference to the operation of incision through a stricture of the rectum, that his experience was limited to two cases; abscess, pelvic cellulitis, and death followed in both.

He recalled one case of intestinal obstruction in a child, where he had opened the abdomen, the constriction was found to be caused by a twist, which was relieved, and a large liquid evacuation followed in five minutes. The operation was too late, being done on the fifth or seventh day after obstruction, and the child died the next day.

DR. A. T. CABOT reported a case of

NEPHROTOMY FOR HYDRONEPHROSIS.[1]

DR. C. D. HOMANS asked if Dr. Cabot supposed that the kidney was normal at the time the boy fell.

DR. CABOT replied that he did not see how that could be determined. He should imagine that a slightly movable kidney or an already existing twist in the ureter would favor the occurrence of a hydronephrosis after injury.

DR. FITZ asked whether hæmorrhage might not have been the cause?

DR. CABOT replied that he thought the clot of blood resulting from a hæmorrhage might act as a first cause of obstruction, and that the distention of the retained urine would then, after the absorption of the clot, tend to prolong the closure of the ureter.

Adjourned.

MASSACHUSETTS MEDICAL SOCIETY, COUNCILORS' MEETING.

A STATED meeting was held at No. 19 Boylston Place, Boston, on February 7, 1883, at eleven o'clock, A. M.

ELECTION OF DELEGATES.

The meeting was called to order by the President, Dr. Alfred Hosmer. After the reading and acceptance of the record of the previous meeting, delegates were appointed to represent the Society at the meetings of other State Medical Societies, as follows: —

[1] See page 173 of this number of the JOURNAL.

Maine: Drs. J. Ayer, of Boston; G. D. Colony, of Fitchburg.

New Hampshire: Drs. F. H. Hooper, of New Bedford; C. Dutton, of Tyngsborough.

Rhode Island: Drs. T. H. Gage, of Worcester; W. N. Stone, of Wellfleet.

Connecticut: Drs. S. L. Abbot, of Boston; G. J. Townsend, of South Natick.

New Jersey: Drs. H. P. Walcott, of Cambridge; G. H. Pillsbury, of Lowell.

Committees were appointed to audit the Treasurer's accounts, to examine the library, to examine the By-Laws of District Societies.

Reports were received from the Committee on Finance, recommending the remission of dues to certain Fellows; also from the Committee on Membership recommending that some members be dropped from the roll for non-payment of dues, and that some others be allowed to retire or resign. The recommendations of these committees were adopted.

LETTER FROM SIR JAMES PAGET.

The following letter, addressed to the Recording Secretary, was read: —

"LONDON, *October* 9, 1882.

"SIR, — I shall be obliged by your offering to the officers and members of the Massachusetts Medical Society my grateful thanks for the honor they have conferred on me in electing me an honorary member of their body. It shall be a motive to me to strive still to do good scientific work.

"I am, sir, obediently yours, JAMES PAGET."

DIPLOMAS. — ADMISSION TO THE SOCIETY. — CENSORS.

In accordance with the recommendation of the Committee on Medical Diplomas it was voted that the Columbus Medical College, of Columbus, Ohio, be dropped from the list of medical colleges whose diplomas are recognized for admission to the Society.

The committee appointed in June, 1882, to report on the subject of admission to the Society responded through Dr. Shattuck. The report stated that it would be very undesirable to apply to the Legislature for any modification of the charter. Experience proves that by-laws should not be abrogated or modified except for urgent cause. The present system of admission to the Society comes from much deliberation and experience, and the growth of many years. Much is being done, and more may still be done, to promote its wise administration. It has not been thoroughly tried, and we should wait till this has been done before we start on a new departure.

The committee offered several resolutions, of which, after considerable discussion, the following were passed: —

Resolved, That the Councilors of the Massachusetts Medical Society hereby call upon District Societies to exercise great discretion and care in the choice of Censors, and exhort all Censors to a faithful and painstaking discharge of their duties as set forth in the By-Laws and Rules.

Resolved, That the Councilors hereby express their approval of stated and occasional meetings of all the Censors, — who may thus confer as to how their responsible duties may be performed to the greatest advantage of the important interests intrusted to them, — and recommend a continuance of these meetings.

Resolved, That the Councilors hereby call the attention of District Societies and Censors to the following matters of great importance: —

All Censors must be elected by ballot, and can only be elected at the annual meetings of District Societies.

No Censor can act as such unless he be present at the meeting. No Censor can act by deputy.

No Board of Censors can hold a special meeting, or adjourn except to a specified time and place.

Every board except the Suffolk Board must hold a meeting whenever there is a stated meeting of its District Society.

Resolved, That a copy of these resolutions be sent by the Secretary to every Censor and to every Secretary of a District Society.

REGISTRATION OF BIRTHS AND DEATHS.

A communication was read from the Berkshire District Medical Society protesting against the existing laws of the State regarding the registration of births and deaths, and requesting the Councilors to petition the Legislature for proper compensation to the profession for the performance of duties which the laws demand. After discussion, on motion of Dr. Amory, it was voted that a committee of five be appointed to present the memorial of the Berkshire District Medical Society in regard to the repeal or modification of the registration law, and to appear on behalf of the Massachusetts Medical Society before the Legislature to request a repeal or modification of sections 7 and 9 of chapter 33 of the Public Statutes.

The following were appointed to constitute the committee: Drs. R. Amory, H. Holmes, A. H. Cowdrey, E. B. Harvey, L. Miller.

Adjourned at 12.30 P. M.

Recent Literature.

Anatomical Technology as Applied to the Domestic Cat: an Introduction to Human, Veterinary, and Comparative Anatomy. With Illustrations by BURT G. WILDER, M. D., and SIMON H. GAGE, B. S., New York and Chicago: A. S. Barnes & Co. 1882.

The readers of the works of any observer noted for the strength with which he holds original and not generally accepted views can hardly help joining the group of his admirers or opponents according as they agree or not with these views, quite irrespective of the merits of the work immediately before them.

We shall endeavor in this case not to follow the common custom. Professor Wilder's views on homologies and on nomenclature have been sufficiently discussed in these pages and elsewhere. We do not share them; but that is no reason why we cannot give well deserved praise for great labor, patience, and knowledge. The student who will carefully dissect a few cats according to the rules given in this book will have a great advantage over the one who begins his work with the human body, and if he will master the instructions for the various methods of preparation, he will know more than most graduates in medicine.

A Guide to the Practical Examination of Urine. By JAMES TYSON, M. D. Fourth edition. Philadelphia: P. Blakiston, Son & Co. 1883.

Previous editions of this book have been favorably noticed in the pages of the JOURNAL. The present edition furnishes evidence of careful revision. A few errors which occur in the third edition have been corrected, and several additions, of such a character as to add to the completeness of the book without increasing much its size, have been made to the text. A colored plate, illustrating Vogel's scale of urine tints, has also been added. We can recommend the book to practitioners and students as the best working guide to the practical examination of urine in the English language.

THE WEIGHT AND DEVELOPMENT OF THE BRAIN AS INDICATIVE OF INTELLECTUAL FORCE.

THE examination of the brain of Gambetta and the reported results have called attention again somewhat, to the relation of the weight of a brain and development of its convolutions to the intellectual force of the individual, and it may not be amiss to recall once more what is known and what is not known in regard to this question.

Gambetta's brain, if the report reaching us was correct, weighed only 1160 grammes, or about thirty-six ounces. This is a very small brain, from whatever point of view regarded, whether from that of age, of sex, of race, or of body stature. The development of the convolutions on the other hand, it is stated, was more than usually varied and well defined. Gambetta must be acknowledged to have been possessed of gifts and acquirements in a marked degree, of the so-called intellectual character, as well as of others of an emotional nature.

Since Gambetta's death we have received the report of the post-mortem examination of a quite well-known gentleman dying in Ohio, Dr. E. H. Knight, formerly employed in the Patent Office at Washington, subsequently one of the American Commissioners to the French Exposition of 1880, and author of the Mechanical Dictionary. He was a man of marked mental activity and vigor, endowed with a phenomenal and very correct memory. His brain is reported as having weighed sixty-four ounces, but we are ignorant of the appearances presented by the convolutions.

We cite these two extreme instances, coming within a few weeks of each other, as showing how difficult it is to arrive at any fixed law in regard to this subject, especially from individual cases. The results reached by Rudolf Wagner, who in 1860 published a table of nine hundred and sixty-four recorded cases in which the weight of the brain had been ascertained, are thus summarized by Quain: First. Although the greatest number of brains belonging to men of superior intellect are found to be heaviest or largest, yet there are so many instances in which the brains of such persons have not surpassed or have even fallen below the average size of the brains of ordinary persons, that superiority of size cannot, in the present state of our knowledge, be regarded as a constant accompaniment of superiority of intellect, even when due regard has been paid to the comparative stature and other circumstances of the individuals. Second. It would appear that, in the brains of certain persons of superior intellect, the cerebral convolutions have been found more numerous and more deeply divided than in those of persons of ordinary mental endowments and without cultivation. But numerous exceptional instances are also found of paucity of convolutions coincident with superior intellect, which makes it impossible at present to deduce any certain conclusion with respect to the relation between the number or extent of the convolutions and the intellectual manifestations of different persons.

Very much the same view is taken by Pozzi in the *Revue d'Anthropologie* for 1878. He is disposed to lay a good deal of stress upon the composition and thickness of the gray substance, and, in regarding the brain as a mixed organ serving both for the elaboration of thoughts and for excitation of direct muscular movements, to consider muscular development as well as stature as a factor. The same view again is taken by Dr. Thomas Dwight in a paper communicated to the American Academy of Arts and Sciences on the brain of a distinguished man.[1]

Age, sex, race, education or intellectual development, muscular development or stature, may be stated as the chief and most constant factors affecting at least the weight of the brain, but any general laws which it has yet been attempted to formulate for these are certainly subject to very numerous exceptions. As to the development of the convolutions and extent and composition of the gray substance, it may be said that no laws, even of the most general character, have yet been suggested, if we except a not very successful attempt by Benedikt, to classify the brains of criminals according to the appearances or absence of certain fissures, and the limited observations of the younger Wagner.

The human brain is found to be absolutely heavier than that of all the lower animals except the elephant and whale. The best observations appear to show that in both sexes the weight increases rapidly up to the seventh year, more slowly to between sixteen and twenty, and again more slowly to between thirty and forty, by which time the maximum weight is attained; subsequently there appears to be a slow but progressive diminution in weight which, according to Boyd, who weighed two thousand and eighty-six brains of sane persons of both sexes dying in the St. Marylebone Infirmary, scarcely begins before sixty years.

The average weight of the brain of the civilized adult male is generally stated at forty-nine and one half ounces, and of the female at forty-four ounces. In a series of two hundred and seventy-eight cases the maximum weight of the adult male brain was sixty-five ounces, and the minimum weight thirty-four ounces; and in a series of one hundred and ninety-one cases the maximum weight of the adult female brain was fifty-six ounces, and the minimum weight thirty-one ounces. These maxima and minima have been surpassed in reported cases, as we shall presently show. As to the relative brain weight in the two sexes, John Marshall[2] states that the "proportion of brain is larger

[1] Mr. Chauncey Wright.
[2] Proceedings of the Royal Society, 1874–75.

in the male than in the female, not only generally but even at corresponding heights, as, for example, in short men as compared with tall women. Evidence [showing] that the well-known sexual difference in the weight of the male brain overrides the influence of stature, which has a tendency to diminish his proportionate amount of brain."

The number of observations upon brains of different races is as yet too limited to be of absolute value, but as far as such have gone would indicate a decided superiority of the European over the semi-civilized or savage races, and a slight superiority in weight of the English or Scotch brains over French or German.

As to the relation of intellectual force and development to the weight of the brain, it can only be said that a number of eminent men in various walks of life — as Cuvier, a naturalist, Knight, a patent lawyer and encyclopedist, Abercrombie, a philosopher and physician, Goodsir, an anatomist, Simpson, a physician, Dirichilet and Gauss, mathematicians, De Morny and Daniel Webster, statesmen, Campbell, a lawyer, Agassiz, a naturalist, Chalmers, a preacher — have had very heavy or average brains, weighing from sixty-four and one half ounces to forty-eight ounces; on the other hand there are instances of idiots with very heavy as well as very light brains, and of eminent men — of whom, perhaps, Gambetta is the most striking example — with brains much below the average.

In regard to the relation of stature to brain weight, Marshall concludes that "all estimates of other influences regulating the brain weights in Man, whether these be sex, age, occupation, education, or disease, are liable to error unless the influence of stature be first eliminated." He finds that "an increase of stature is accompanied by an increase in the absolute weight of the encephalon in both sexes, and that, notwithstanding this absolute increase of the encephalon and its parts in obedience to an increase of the stature, the increase itself is not *pari passu* with the stature; on the contrary, there is a gradual and progressive relative diminution in the proportion of encephalic substance to the stature as this latter itself increases."

As a few exceptions to the usually received opinions in regard to brain weight we have selected the following from various sources: —

In the *British Medical Journal* for 1872 we find the report of a brain of a boy thirteen years of age, who "had been a particularly healthy lad, showing no evidence of rachitis, and very intelligent." He died from injuries caused by a fall from an omnibus. The brain weighed fifty-eight ounces. Dr. Batty Tuke reported in the same journal in 1872 the brain of an idiot which weighed sixty ounces; the cerebellum, however, was deformed, the left half showing numerous abnormal convolutions. In the same volume of the same journal is reported a brain which weighed sixty-seven ounces. The owner was a bricklayer, a man thirty-eight years old, five feet nine inches and a half in height, "could neither read nor write, was not very sober, had a good memory, and was fond of politics." In the collection of the Army Medical Museum at Washington is a brain of the remarkable weight of seventy-three and one half ounces. It was taken from a Chippewa Indian squaw, hydrocephalic and a dwarf. The Proceedings of the Connecticut Medical Society for 1878 contain a report of a female brain weighing fifty-nine ounces. The person is stated to have been of medium stature, body weight one hundred and twenty-five pounds, large head, and nervous temperament, and to have possessed more than average mental ability. She became insane, and committed suicide. Boyd's large series of 2086 brains were taken from the lower classes of London, and yet give an average weight.

In regard to the weight of the brains of the insane, Dr. W. G. Balfour, writing in the *Edinburgh Review* for 1872, and comparing his results with previous figures of Drs. Thurnam, Peacock, and Skae, is inclined to the conclusion that insane brains vary from sane as regards weight in being slightly lighter; that this is dependent on a decrease in the weight of the cerebrum, there being no loss of weight in the cerebellum, and that the cases of chronic insanity and dementia in which serous effusions and œdema of the brain substance are so often met with furnish a probable cause for the decrease. There seems no reason to suppose that in cases of recent insanity any difference between the weights of sane and insane brains is to be detected.

HYDRIATRY.

COLD water has been in all ages recognized as a remedial agent of great power. Irrigations, baths, and epithems, were recommended by Hippocrates, who learned the medicinal uses of water in Egypt. He inculcates the importance of cold drinks and cold epithems in fevers, of cold affusions in hysteria and tetanus, and even in gouty and rheumatic inflammations of the joints, though he says in these cases cold applications should be used with great care. According to Celsus, a certain Petro used to "cover his fever patients with a great many clothes, that he might excite both heat and thirst, whereupon he gave cold water to drink, and if it raised a sweat he pronounced the patient out of danger."

Aetius recommends cold bathing and cold douches for menorrhagia and sexual debility, and many of his modern successors have found the external employment of cold water invaluable in these cases.

Charmis, of Marseilles, in the century in which Pliny lived, recommended all who wished to preserve their constitutional vigor to an extreme old age to take a cold plunge every day, the bath not to be omitted even in the winter season; a regimen which multitudes in his time adopted, and from which many since his day claim that they have derived strength and recuperation. We remember even to have read in the life of that distinguished statesman and representative of modern culture, who was familiarly known as the "Old Man Eloquent" (the late John Quincy Adams), that regularly as the early morning hour arrived he was seen to repair to the river near his dwelling for his customary plunge; in the cold of the winter he used

to take his morning bath through a hole in the ice. The venerable statesman was free to attribute his wonderful constitutional robustness, his freedom from colds, pulmonary troubles, rheumatisms, etc., to the invigorating effects of his daily bath in the river.

Galen treats largely of the uses of cold water in sickness. This author recommends cold drinks and cold epithems in constipation of the bowels; a remedy which certainly sometimes works exceedingly well. We have known severe cases of constipation to be overcome by drinking a goblet of cold, spring water, the last thing at night and the first thing in the morning (the morning draught may for a time, if expedient, be medicated with a teaspoonful of Glauber, Epsom, or even common salt); cold, wet compresses over the abdomen may sometimes be used to great advantage.

Perhaps no event in modern times, till we come down to the epoch of Priessnitz, has tended more to popularize the cold water treatment of disease, than the publication by S. Hahn, in 1738, and J. S. Hahn, in 1745, of two celebrated treatises on the properties and uses of cold water. These physicians lived in Prussian Silesia, not far from Graefenburg, the home afterward of Priessnitz, and their works, according to Stillé, contain a full account of the medicinal uses of cold water, including its application to almost every known disease. We cite from Stillé the following illustration of their mode of treatment: "A lady was affected in almost all her joints with gout, which had resisted every method of treatment. At last she was treated in the following manner: Cold affusions and lotions upon the bare head and body; wrapping in sheets soaked in cold water, and which were kept constantly wet for the space of two nights and two days; she sweated and recovered." This rather heroic treatment of acute gout would, we think, find few imitators at the present day.

Hydriatry was still further brought into vogue by the cold-water treatment of fevers by Jackson and Currie, the latter part of the eighteenth century. Both of them, according to the same authority from whom we have just quoted, were led by fortuitous circumstances to the adoption of this practice. "Jackson, by learning that some twenty years before a number of patients on board a hospital ship, had, in the delirium of fever, thrown themselves into the sea, and that the survivors from drowning were restored to their senses." Currie was indebted to the observations of Dr. Wright, published in 1786, the latter having noted the beneficial effects of cold affusions in fever.

Next comes the era of Priessnitz, and the impulse given by him, as a result of empirical observation, to modern hydriatry. This has been fully dwelt on in the lecture which we publish to-day, in which are described the uses of cold water in nervous diseases, and the divers modes of application. The efficacy of continuous cold applications to the head and spine in cerebral and spinal inflammations is undoubted; here the process of irrigation has found much favor. The *modus operandi* of cold in these cases, in repelling blood from the meninges, is sufficiently understood. That some functional nervous diseases are also benefited — sometimes permanently — by cold douches and cold baths, is also established, though precisely how the "shock," followed by the "reaction," operates, is still obscure. Further study on these points is needed.

The application of cold water in disease is to be recognized as a remedial agent of considerable power, and not to be ordered carelessly and indiscriminately. Our readers will find the lecture on this subject in the present issue of the *Journal* of much interest.

THE FINANCIAL PROBLEM IN THE ENGLISH HOSPITALS.

A CONSIDERABLE falling off in the income of some of the London hospitals has occurred. Four of them have found it necessary during the past year to pay a considerable fraction of their current expenses out of a gradually decreasing reserve. In the case of King's College Hospital the income fell short of the expenditure by £9500; at St. George's the deficiency was £8000; at University College Hospital it was £6000; and at the Westminster Hospital £4000. This deficiency is believed to be due, in part, to the establishment of "Hospital Sunday," with the origin of which, at all events, it was coincident. This method of giving enables persons who have formerly contributed large sums under the glare of a wide-spread publication of subscription lists to make their contributions secretly. It seems that when the left hand does not know what the right hand does, the latter sometimes does less than it otherwise might.

According to figures given in the *British Medical Journal* it would seem that probably the aggregate sums contributed in charity for hospital maintenance were not decreasing, but that the falling off in the receipts of the large general hospitals is counterbalanced by the sums given to the great number of small, special institutions, as those for women, for children, for nervous diseases, and the cottage hospitals, which have sprung up in late years, and which provide for cases formerly treated in general establishments. It is worthy of note that the large pay-hospitals are not suffering from the financial stringency, which suggests a way in which the funds of the other institutions may be replenished, namely, by adding pay-wards for private patients, and by an endeavor to collect even from poor patients a small sum proportionate to their ability. We are inclined to think that in this country at least there is enough gratuitous hospital care furnished, and that if enlarged accommodations are demanded, they should be paid for, in part, at any rate, by their beneficiaries, who will thereby be saved from the undesirable effects of absolute alms-taking.

MEDICAL NOTES.

— Permanganate of potassa seems to be the latest wrinkle among the medical quidnuncs. Injections of Condy's fluid have long been well thought of for

gonorrhœa. And Drs. Ringer and Murrell (*Lancet*, January 6th) strongly recommend the pills as a cure for amenorrhœa. It is said, however, that permanganate of potash when made up with any readily oxidized excipient, as glycerine, has an unpleasant way of "going off." If it should deflagrate when administered *per vias naturales* it would be startling. But then it is to be said, that if this reaction is a common result of such a combination their topical application to the uterine cavity might reasonably be expected to relieve amenorrhœa.

— We have received the first number of *Science*, a new weekly of neat exterior, and twenty-six quarto pages of reading matter. It is edited by Mr. Samuel H. Scudder, and owned by a company, the president of which is President Gilman of Johns Hopkins University. *Science* will be published at Cambridge. According to the prospectus it "will be a strictly independent journal, devoted to the advancement of knowledge and scientific research in America, and will be technical only in so far as the subject-matter may require. On the one hand it will claim the support of scientific men as the most available channel for the early publication of condensed results of their researches, and on the other it will appeal to the intelligence of the general public by its careful exposition of scientific discovery, while both will profit by its weekly reports of scientific progress, drawn from original sources of the very latest date, and from all parts of the world."

— The Medical Record Visiting List or Physician's Diary is one of the neatest and handiest offered to the profession.

— It is said that the czar of Russia has broken up the medical college for women at St. Petersburg, which was founded by his father, the late czar.

— Block, of Dantzic (quoted in Annals of Anatomy and Surgery, December, 1882), has been experimenting with a view to ascertaining the feasibility of operative surgery upon the thoracic viscera, and reports that he has a number of times opened the thorax in dogs and sewed up purposely made rents in the heart muscle after laying the pericardium freely open; in a considerable number of cases the animals survived this operation. He also resected the lungs in a large number of dogs, removing from one to four lobes, and several of the largest animals lived for months.

NEW YORK.

— On February 5th Mr. Seymour Haden gave the first of two lectures at Chickering Hall on the principles and practice of etching. In speaking of his own work as an etcher he said, "It could hardly be expected that an amateur could take it up successfully. It may be said that I am an amateur, but I wish to say that I began the study of art the day I began the study of medicine, and have continued the study ever since. While my days were spent in the dissecting room, my nights were spent in the schools of art. To that I may add my experience as a collector, and also the fact that I never published an etching until I was an expert."

— One effect of the adoption of the new Code of Ethics last year, and the effort to sustain it at the recent meeting of the State Medical Society, has been the introduction into the Legislature at Albany of a most outrageous bill, which provides that no State or county medical society shall adopt any rule or regulation which shall prevent members of such societies from consulting with any legally authorized practitioners of any school, and that all rules or regulations prohibiting such consultations shall be null and void. This extraordinary measure was received with no little favor by a large number of the Solons present, but some of them had sufficient sense of decency to secure a postponement of action in regard to it.

— At the meeting of the New York Society of Medical Jurisprudence, held February 8th, Dr. William A. Hammond read a paper on Intellectual Monomania, with Depression, in its Medico-Legal Relations, as Illustrated by the Case of Dubourque, the Fourteenth Street Assassin. Dubourque, it will be remembered, is the maniac who stabbed several women, one of them fatally, on Fourteenth Street, New York, when crowded with pedestrians, in October last. This disorder, Dr. Hammond said, differed in its symptoms and causes from both emotional insanity and melancholia, and one of its most striking characteristics was the patient's delusion that he was the victim of persecution. It was often the case that he believed that whole bodies of men were banded together against him. When examined after his arrest Dubourque spoke glibly on other subjects than that of his crime, both in French and English, and, as it was evident that he was shamming for a purpose, Dr. Hammond decided that he was insane, but was able to distinguish between right and wrong, and therefore amenable to punishment. His mania, as well as that of his father, with whom he walked the streets with placards accusing the government of having cheated them out of a large inheritance, was caused by the disappointment of not receiving an expected legacy from the old man's brother, who died in California. The legal question suggested by this case, Dr. Hammond said, was whether or not the city was liable for damages when it allowed a man like Dubourque, who had been, previous to his last exploits, arrested for an attempted homicide, and acquitted on the ground of insanity, to go at large.

An interesting discussion of this question by the lawyers present followed. Mr. Livingston said that as the corporation owed protection to all citizens, it was liable for a neglect of this duty. Mr. Miller thought that the city could be prosecuted for criminal negligence for acts committed by irresponsible individuals, of whose irresponsibility, as in Dubourque's case, it had constructive notice. Mr. Brooks said the acquittal of a criminal on the ground of insanity was not such notice to the corporation as would serve for the grounds of an action for damages, but that the person whose duty it was by law to commit a declared lunatic to an asylum might be liable for injuries consequent on his neglect of such duty. Mr. Linderburg believed that it was quite within the discretion of a judge, who might be satisfied that a man who was acquitted on

the ground of insanity at the time his crime was committed and might have afterwards become sane, to discharge him, and that in any event a magistrate could not be prosecuted for a judicial act in an action for damages. In this opinion several other legal gentlemen coincided. Dr. Spitzka, who also examined Dubourque, differed from Dr. Hammond in his opinion that the murderer's knowledge of right and wrong was not obliterated by his disease, which was General Paresis, at the time he stabbed the women. His examination convinced him that he was wholly irresponsible, and that his insanity was incurable.

— A somewhat similar case to that of Dubourque has just occurred in Bellevue Hospital, although in the latter instance the insanity seemed to be clearly attributable to alcoholism. On January 31st a man by the name of Mahon, an engineer by occupation, was admitted to the hospital apparently on the verge of delirium tremens. Under the treatment to which he was subjected he improved so much, however, that he was discharged the following day. He then immediately commenced drinking heavily again, and on February 3d was readmitted to the hospital. He was at first confined in a cell, but the next morning was given the freedom of the corridor and waiting-room. The keeper in charge did not seem to anticipate any danger, although the man was very despondent, and kept muttering to himself about being pursued by persons who wished to kill him. Suddenly he became violent, exclaiming, "There he is. He has a pistol, and is going to murder me," and before he could be secured he had fractured the skulls of a fellow-patient and the keeper with a three-legged stool and an earthenware spittoon, which were in the corridor. The patient, who was sitting quietly at a table reading at the time, died instantly, but it is thought that the keeper may possibly recover.

— By the will of the late Samuel Willets a bequest of $50,000 each is made to the Hospital for the Relief of the Ruptured and Crippled and to the New York Infirmary for Women and Children, of both of which institutions he was president at the time of his death. He also left $50,000 to the New York Hospital, and $5000 each to a number of dispensaries and other medical charities.

— The State Board of Charities has declared that the insane asylum at Mineola, Long Island, is overcrowded, and directed that the buildings must either be enlarged or some of the patients removed to other institutions.

— According to the newspapers a negro woman, Caroline Townsend, has lately died at Flushing, L. I., at the remarkable age of one hundred and twelve years.

— The proceeds of the annual Purim charity ball (Jewish) at the Academy of Music will this year be devoted to the support of Mount Sinai Hospital.

— Mr. William E. Dodge, one of the most benevolent citizens of New York, died suddenly on the 9th of February. The last time that he was out it was to visit a building which he had recently purchased, and had been fitting up for a home for inebriate women.

Correspondence.

CONCERNING NEWPORT, R. I., AS A RESORT FOR CONSUMPTIVES.

MR. EDITOR, — In the *Sanitarian* of January 18th and 25th, an article headed Newport in Winter gives statistics in reference to pulmonary consumption, and says, among other things, "Newport has been recommended by eminent physicians as a desirable winter resort for consumptives, and they present facts and figures," etc., etc.

These "facts and figures" are compiled by Dr. H. R. Storer, of Boston, and so far as they alone are concerned are perfectly correct. It is shown that Newport has a smaller ratio of mortality from consumption, both as compared to the population and the total mortality from all causes, than any other locality in Rhode Island; and, further, that in this State the ratio of mortality is smaller than anywhere in this country except the Northwestern States. The only objection to this finding lies in the fact that Newport as a city is not the only one of its size on the Atlantic coast with such small percentage of deaths as mentioned (12.92 per cent. of all causes).

What appears to me to be a grave error, and one which in its bad effects may become far-reaching, are the conclusions certain to be drawn from this recommendation. The errors and false conclusions are as follows: —

Certain constituents of climate and soil favor the development, — are the *causes* of consumption. Certain other constituents favor the arrest, more or less permanent, of consumption. These may be said to be some of the elements of repair, of *cure*.

Secondly, it by no means follows that because a certain section of country does not favor the development of consumption in its inhabitants therefore is the climate of that section suitable for the cure or arrest of consumption. Neither is it an argument against that particular section, but it is dangerous doctrine to preach.

Now I put up two propositions, and will endeavor to prove them as tersely as possible: —

(1.) That the climate and soil do not particularly favor the development of phthisis among its inhabitants.

(2.) That the climate and soil are inimical to the arrest or cure of phthisis in any of its forms.

Proposition I. The figures show a relatively small mortality from phthisis, and this speaks for itself. Of all causes by which the *exposed* on the one hand (overcrowding and bad food), and the *sensitive* on the other (hereditarily vulnerable with irritable mucous membranes and skins), are found to develop phthisis, subsoil moisture is the greatest. This has been abundantly proven by Dr. Bowditch and Dr. Buchanan. The original character of the soil and the drainage, natural and artificial, determine the quantities of surface or ground-water likely to be retained. Health reports from Newport show that both as to soil and drainage the city is as near perfection as any city on the Atlantic. Moreover, Newport is not a city of such dimensions as to make overcrowding a prominent factor. The population of 16,000 is not remarkable, nor do we hear much of poverty; much, however, do we hear of wealth and general comfort.

Proposition II. We have the statistics of the mortality from phthisis among the comparatively well-to-do

inhabitants. We have none of arrest or cure of phthisis of patients who have gone there, nor of those who reside there. Are we at liberty to imagine that the mortality showing is likewise a showing of the whole number of those stricken with consumption or something akin to it?

The chief elements of climate are pressure, temperature as to means and range, humidity, intensity of sunlight, electricity, the production of ozone, and the admixtures in the air. Without going into detail as to what we now know of the effect of these various constituents upon the several forms of consumption, let me unhesitatingly say that *dryness* is the chief desideratum. And what may be called a dry atmosphere? According to Vivenot a climate may be called dry when below fifty-five per cent. of saturation (one hundred per cent. represents saturation); moderately dry, fifty-six to seventy per cent.; moist, seventy-one to eighty-five per cent.; excessively moist, eighty-six to one hundred per cent.

Now we do not find fault with a climate in which the mean relative humidity is of the moderately dry (or moderately moist, which is the same thing), provided it is accompanied by a warm (not hot) or cool climate, and a moderate monthly and annual range. This therapeutical law is absolute for a certain class of patients: dryness with or without high altitude, which excludes equability in our zone; for another class, the "irritable," equability of temperature with dryness, or, rather, moderate dryness, because equability and dryness are not found in anything but relative company, if I may so express myself. Now, let us see where Newport stands as to relative moisture and equability of temperature. I quote from the Signal Service Report of 1880: —

MONTHLY AND ANNUAL MEAN RELATIVE HUMIDITY.

July	73.4	January	76.5	
August	77.2	February	74.0	
September	77.6	March	70.2	Annual
October	74.3	April	70.4	Mean, 74.7
November	76.1	May	73.4	
December	80.3	June	73.0	

Annual mean of seventy-four per cent. of saturation; one month — and that a *winter* month — eighty per cent., and only twice as low as seventy per cent.

Now as to equability, shown by the —

MONTHLY AND ANNUAL RANGE.

July	32° F.	January	46° F.	
August	32°	February	53°	Maximum 86°
September	35°	March	45°	Minimum 2°
October	50°	April	37°	Annual range,
November	50°	May	47°	84°
December	51°	June	37°	

Equability of temperature may be said to exist, broadly speaking, where monthly ranges are below 25° F., and the annual range not above from 30° F. to 40° F. (maximum 80° F., minimum 40° F.)

Here we have for Newport monthly ranges of 32° F., and from that up to 53° F., and an annual fluctuation of eighty-four degrees. In short, not one of the elements of climate which are suitable for consumptives.

But this is not all. Fully granting the comparative immunity of the inhabitants of Newport from consumption, let us look to what we may expect of acute inflammations of the respiratory organs. The Rhode Island Registration Report for 1880 gives the total number of deaths from pneumonia and congestion of lungs in Newport city as 11, in the Newport County towns only 7, and a total for sixteen years in Newport County of 230 deaths. Bristol County has 171 deaths from the same cause. These figures are neither remarkably high nor very low.

The point I wish to make in connection with acute inflammations of the lungs is this: The concurrence of excessive moisture, sudden fluctuations of the thermometer, and high winds favor the development of these troubles. To the chronic cavity or infiltration of a consumptive acute inflammations are in the nature of an exacerbation of the original trouble. The climatic conditions which assist in bringing about this state of affairs may be found at Newport, "recommended as a winter resort for consumptives." Further comment is unnecessary. Respectfully yours,

J. HILGARD TYNDALE, M. D.
31 EAST TWENTY-SECOND STREET, NEW YORK.

A "VINDICATIVE" LETTER.

MR. EDITOR, — Your announcement and comment on my Manual in your issue of January 25, 1883, page 89, appears to my humble judgment anything but fair. You take the liberty in describing the color of paper, odor, etc. I feel assured you have never participated in country printing. I presume you are not aware that this little "rag-edged pamphlet" cost fully as much as a handsomely printed octavo volume in the enlightened city of Boston. The two abstracts that you refer to, on pages 19 and 22, was eagerly looked for. Lord Bacon says, "Read not to contradict, to confute, nor to believe and take for granted, nor to find talk and discourse, but to weigh and consider. The mind which is searching for truth ought to remain in a state of suspense until superior evidence on one side or the other incline the balance of the judgment and determine the probability or certainty to the one side." "But yet this truth being never so certain, never so clear, he may be ignorant of either, of all of them, to take pains to employ his faculties as he should to inform himself about them." Locke.

I here publicly profess I will to the end of my days acknowledge as the greatest obligation that any person can confer upon me if, in the spirit of meekness, he will point out to me any error or enthusiastical delusion into which I have fallen.

I have admitted in the preface of the Manual that for its origin I am indebted to "Joh. Fred. Faselii Elementa Medicinia Forensis." I will concede I am guilty of negligence and rational hypothesis for not commuting the above-mentioned abstracts into the latest advancement of science. I despise deceit, and lay no claims to superior wisdom and infallibility, but I hate to be made out an unwarrantable quack. I have but one consolation, "That unwarlike learning which is nourished by ease, and flourishes by praise and reward, which sustains not vehemency of opinion, and is the sport of artifices and impostures, is overthrown by opposition." Lord Bacon.

There is a German proverb, "Thue recht und scheue niemand." I will always avow what is due to science. As Baron Humboldt says: "Ce servit faire tort au progrès des sciences que de ne pas vouloir abandonner des théories contraires aux observations que presente l'état actuel de nos connoissances."

I never sought eminence, but I have taken a solemn pledge before the altar of Galen to try and honorably act in the progress of my chosen profession. Now what a legacy is there for me? What a reward for all that is true and noble to me, and for all that is softest and best in a physician's life? A bad name, a pledgeist, a literary quack. I can only say as Iago in Othello: —

> "He that filches from me my good name,
> Robs me of that which not enriches him,
> And makes me poor indeed."

I make these observations, sir, not with any desire to make you deviate by an hair's breadth from the path of duty which you are bound to tread as editor of a scientific medical journal, but I make them to pray, to entreat, to beseech you, with the last stroke of my pen, hereafter not to bestow your opinion upon speculative theories and visionary ideas, but to try and accurately weigh in every particular the character and standing of man.

C. H. VON KLEIN.

HAMILTON, OHIO, *February* 8, 1883.

THE VAGINAL DOUCHE.

MR. EDITOR, — Having seen in your journal several illustrations of apparatus for using the vaginal douche, I desire to give a description of one I have used for several years, and which I believe to be equally efficacious, though more convenient and simple than any other.

It consists of a small cot (made of ordinary rough lumber), three feet long and two feet wide, the upper surface of which is concave from side to side and slopes from behind forwards with a fall of about two inches. It is made low, so that it can be pushed under the bed when not in use, and for that purpose I put rollers under the feet. A piece of rubber cloth, extending over the front, is laid on the top of the cot, and a common tin pan placed on the floor in front of it. I always use the fountain syringe with a capacity suitable to each case, which can be refilled, if necessary, by the patient or an attendant. Closing the stop-cock while filling the syringe, it is opened to expel the air, and then closed again. Then the patient, with the nozzle of the syringe in her hand, lies on the cot, places her feet, one on each side of the front edge, and a pillow under her head. After introducing the nozzle, the stop-cock is opened, and the injection, as it runs from her, must run into the pan.

Very respectfully yours, D. M. APPEL,
Assistant Surgeon U. S. Army.

FORT ELLIOTT, TEXAS, *February* 3, 1883.

Miscellany.

SCHOOLS OF MEDICINE.

THE difficulty in getting before the public the facts concerning the non-sectarian position of rational medicine makes it cause for satisfaction whenever a correct presentation of the attitude of the medical profession is made in any leading periodical. From a paper by Dr. R. O. Beard in the *Popular Science Monthly* for February, 1883, we make the following quotation: —

"Nothing is so popular as prejudice, and no prejudice so popular as that resting upon a supposed scientific basis, or backed by reputed scientific authority. Always obstructive to the spirit of progress, it is peculiarly so when related to a subject so closely concerning the interest of the people as the study and treatment of disease. In these physically degenerate days the avoidance or remedy of the thousand 'ills which flesh is heir to' is a question of well-nigh universal import. The urgency of this common need offers a partial reason for the adoption and perpetuation, by the public mind, of the differences which are supposed to exist between the two great schools of medicine, while, at the same time, it measures the greatness of the misfortune of the fact.

"Rooted in the professional ignorance and bigotry of almost a century ago, fostered by the bitter rivalries and exclusivism of opposing theorists, these differences have been taken up and fed by popular opinion, until they seriously embarrass the progress of medical knowledge, and tend to destroy all faith in the science and art of healing.

"The medical fraternity at large, and of both schools alike, is responsible for this unfortunate condition of affairs. When professional men who, supposably, represent the best phases of liberal thought and scientific culture lend their names to the partisanship of mere theory, and array themselves under sectarian titles which signify their adherence to an exclusive dogma, it is small wonder that the laity should follow in their footsteps and cast their views into the yet narrower mould of unreasoning prejudice. And, as professional hands have sown this seed of error, it is they who must gather its barren harvest and uproot the tares of false opinion from the popular mind."

CONVALLARIA MAJALIS. THE OTHER SIDE.

DR. B. STILLER, in the *Wiener Medizinische Wochenschrift*, adds his experience to the observations on convallaria majalis, which, it will be seen, is of different tenor from that of the Russians, who introduced it, and of M. Germain-Sée, who first made it prominent.

Seventeen persons were treated by Stiller, some for relapses, making a total of twenty-one cases, fifteen of whom were males; the ages varied from eleven to seventy years, and the diseases were four cases of mitral insufficiency with aortic regurgitation, one of pure mitral regurgitation, five of regurgitant and stenotic mitral disease, four of mitral stenosis, five of weak heart with dilated left ventricle, and, lastly, two cases of Graves' disease, altogether a motley group of cardiac diseases. Out of the twenty-one cases seventeen gave absolutely negative results with convallaria; there was not the least influence on the frequency or rhythm of the heart's action. Some of these cases proving intractable to convallaria were subsequently benefited by digitalis; two individuals experienced a certain degree of the diuretic effect of the new drug without any of the other vaunted phenomena, not even the dropsy being diminished; two patients underwent decided improvement in most of the cardiac symptoms during the use of the new medicine, but these cannot outweigh the large balance of negative results.

It will be remembered that the advocates of this drug claimed for it all the advantages of digitalis in regulating the frequency and rhythm of the heart beats, increasing the strength of the contractions, and raising the blood pressure, and without any of the dangers of the cumulative action of digitalis.

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 10, 1883.

Deaths reported 2767 (no report from New Orleans): under five years of age 1051: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 520, consumption 400, lung diseases 374, diphtheria and croup 180, scarlet fever 99, small-pox 63, typhoid fever 33, diarrhœal diseases 26, cerebro-spinal meningitis 24, measles 23, whooping-cough 23, malarial fevers 19, erysipelas 16, puerperal fever 13, typhus fever one. From *typhoid fever*, Philadelphia eight, New York and Pittsburg four each, Chicago, Boston, and Cincinnati three each, Baltimore and Buffalo two each, District of Columbia, Providence, Charleston, and Wakefield one each. From *diarrhœal diseases*, Boston seven, New York six, St. Louis three, Brooklyn, Baltimore, Cincinnati, and Nashville two each, Chicago and District of Columbia one each. From *cerebro-spinal meningitis*, New York seven, Chicago three, St. Louis, Milwaukee, and Lynn two each, Baltimore, Buffalo, Providence, Charleston, Nashville, Lowell, Holyoke, and Marblehead one each. From *measles*, New York 15, Nashville two, Brooklyn, Chicago, Cincinnati, Pittsburg, Providence, and Chicopee one each. From *whooping-cough*, New York 10, Brooklyn and Pittsburg three each, Cincinnati two, Chicago, St. Louis, New Haven, Fall River, and Chicopee one each. From *malarial fevers*, New York nine, Brooklyn four, St. Louis and Baltimore two each, Chicago and New Haven one each. From *erysipelas*, New York four, Philadelphia and Boston three each, Brooklyn and Buffalo two each, Cincinnati and Providence one each. From *puerperal fever*, St. Louis three, Chicago and Boston two each, Brooklyn, Cincinnati, Nashville, Springfield, New Bedford, and Peabody one each. From *typhus fever*, Baltimore one.

One hundred and seventy-seven cases of small-pox were reported in Baltimore, Pittsburg three, Lawrence one; diphtheria 31, scarlet fever 20, typhoid fever 10, in Boston; scarlet fever 17 and diphtheria seven in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of 1,052,318 (population of the State 1,783,086), the total death-rate for the week was 21.25 against 20.78 and 20.32, for the previous two weeks.

In the 28 great towns of England and Wales, with an estimated population of 8,620,975, for the week ending January 27th, the death-rate was 22.4. Deaths reported 3703: acute diseases of the respiratory organs (London) 369, whooping-cough 129, scarlet fever 87, fever 59, measles 52, diarrhœa 37, diphtheria 36, small-pox (London eight, Nottingham, Sheffield, and Newcastle one each) 11. The death-rates ranged from 12.7 in Brighton to 31.1 in Liverpool; Leicester 16.1; Birkenhead 18.2; London 20.4; Birmingham 22.9; Leeds 24.3; Sheffield 27.2; Manchester 28.9; Sunderland 30.6. In Edinburgh 21.2; Glasgow 29.7; Dublin 34.9.

The meteorological record for the week ending February 10th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 9, 1883, TO FEBRUARY 16, 1883.

BROWN, JOS. B., lieutenant-colonel and surgeon. Detailed as member of board for examination of assistant surgeons for promotion and candidates for admission into the medical corps, U. S. Army, to convene at New York City on March 1, 1883. Paragraph 1, S. O. 35, A. G. O., February 10, 1883.

CLEMENTS, BENNETT A., major and surgeon. Detailed as member of board for examination of assistant surgeons for promotion and candidates for admission into the medical corps, U. S. Army, to convene at New York City on March 1, 1883. Paragraph 1, S. O. 35, A. G. O., February 10, 1883.

JANEWAY, JOHN H., major and surgeon. Detailed as member of board for examination of assistant surgeons for promotion and candidates for admission into the medical corps, U. S. Army, to convene at New York City on March 1, 1883. Paragraph 1, S. O. 35, A. G. O., February 10, 1883.

TOWN, FRANCIS L., major and surgeon, is relieved from duty at Fort Walla Walla, and will report to the commanding officer, Vancouver Barracks, for duty as post surgeon. S. O. 1, Department of the Columbia, January 27, 1883.

WOODWARD, J. J., major and surgeon. The extension of leave of absence on account of sickness, granted October 6, 1882, is further extended six months on account of sickness. Paragraph 9, S. O. 34, A. G. O., February 9, 1883.

TAYLOR, MARCUS E., captain and assistant surgeon. So much of S. O. 20, A. G. O., January 24, 1883, as directs him to report in person to the commanding general, Department of the East, is amended to direct him to report in person to the commanding officer, David's Island, New York Harbor, for duty at that station. Paragraph 2, S. O. 33, A. G. O., February 8, 1883.

THE "HAMMOND PRIZE" OF THE AMERICAN NEUROLOGICAL ASSOCIATION. — The American Neurological Association offers a prize of five hundred dollars, to be known as the William A. Hammond Prize, and to be awarded at the meeting in June, 1884, to the author of the best essay on the *Functions of the Thalamus in Man*.

The conditions under which this prize is to be awarded are as follows: —

(1.) The prize is open to competitors of all nationalities.

(2.) The essays are to be based upon original observations and experiments on man and the lower animals.

(3.) The competing essays must be written in the English, French, or German language; if in the last, the manuscript is to be in the Italian handwriting.

(4.) Essays are to be sent (postage prepaid) to the Secretary of the Prize Committee, Dr. E. C. Seguin, 41 West Twentieth Street, New York City, on or before February 1, 1884; each essay to be marked by a distinctive device or motto, and accompanied by a sealed envelope bearing the same device or motto, and containing the author's visiting card.

(5.) The successful essay will be the property of the Association, which will assume the care of its publication.

(6.) Any intimation tending to reveal the authorship of any of the essays submitted, whether directly or indirectly conveyed to the committee or to any member thereof, shall exclude the essay from competition.

(7.) The award of the prize will be announced by the undersigned committee, and will be publicly declared by the president of the Association at the meeting in June, 1884.

(8.) The amount of the prize will be given to the successful competitor in gold coin of the United States, or, if he prefer it, in the shape of a gold medal bearing a suitable device and inscription.

Signed, { F. T. MILES, M. D., *Baltimore.*
J. S. JEWELL, M. D., *Chicago.*
E. C. SEGUIN, M. D., *New York.*

No essay of sufficient originality having been sent to the committee this prize is again offered to universal competition.

E. C. SEGUIN, *Secretary.*

AN ARMY MEDICAL BOARD has been ordered to assemble at the Army Building, corner of Houston and Greene Streets, New York City, New York, March 1, 1883, for the examination of such persons as may be properly invited to present themselves before it as candidates for appointment in the medical corps of the army, and will probably continue in session about three months.

All candidates for appointment in the medical corps must apply to the Secretary of War for an invitation to appear for examination. The application must be in the handwriting of the applicant, must state date and place of his birth and place and State of which he is a permanent resident, and must be accompanied by certificates based on personal acquaintance from at least two persons of repute as to citizenship, character, and moral habits; testimonials as to professional standing from professors of the medical college at which he graduated should also accompany the application if they can be obtained. The candidate must be between twenty-one and twenty-eight years of age (without any exceptions), and a graduate of a regular medical college, evidence of which, his diploma, must be submitted to the board.

Further information regarding these examinations and the nature thereof can be obtained by addressing the surgeon-general, U. S. Army, Washington, D. C.

CENSORS' MEETING. — The Censors of the Suffolk District Medical Society will meet for the examination of candidates at 19 Boylston Place, on Thursday, February 22, at three o'clock.

H. C. HAVEN, *Secretary.*

SUFFOLK DISTRICT MEDICAL SOCIETY. — There will be a regular meeting of the Society on Saturday, February 24th, at 19 Boylston Place, at 7.45 P. M. Reader, Dr. J. H. Warren. Subject, Tissue-Repair. Supper at the usual hour.

H. C. HAVEN, *Secretary.*

THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT. — The Society will meet at the Medical Library, 19 Boylston Place, at eight P. M., Monday, February 26, 1883. Reader, Dr. J. Orne Green. Subject, The Action of Quinine upon the Ear.

E. M. BUCKINGHAM, M. D., *Secretary.*

Original Articles.

SOME TYPHOID EPIDEMICS OF THE PAST DECADE, AND THE NECESSITY OF COMPULSORY DISINFECTION.[1]

BY MORTON PRINCE, M. D.,
Assistant City Physician, Boston.

IN this country, as I have said before, we have, fortunately, not as yet been visited by such terrible epidemics as have occurred in England and on the Continent, but it may happen at any time, the next week, perhaps, or the week after, that one of our neighboring towns, now esteemed happy in its healthfulness, may meet with a disaster which will teach us, when it is too late, the lesson we should be learning to-day.

We learn from the last report of the Board of Health that the sewage of the town of Natick, a town of over eight thousand inhabitants, is daily passing into Cochituate lake, being only opposed by a dam, through which it filters. There can be little doubt that the only thing which saves us from some extensive epidemic in this city is the vast dilution which this filth undergoes before being consumed. How long this safeguard will last no one can say. Whatever amount of sewage fails to reach the consumer of water is settling to the bottom of the lake, there to form a sediment of greater or less extent. If any one doubts this let him some day take a long stick, stand on the embankment of Charles River, and poke up the mud and filth on the bottom. It is only a difference of quantity in the two cases, not of quality.

I am willing to predict that some time in the future, unless some remedy is applied, perhaps during a season of drought, the quantity of sewage in the lake will become so great as to produce an epidemic of typhoid, which will spread throughout the city, sparing neither rich nor poor.

In the country towns to-day throughout the State the wells are commonly sunk close to the privies, into which the discharges of those sick with the fever are daily thrown, to a great extent without disinfection, to take the chances of serving as foci for future disease. In the city they are thrown into the drains. Who shall say what proportion of the cases which occur in Boston to-day are due to the spontaneous origin of the poison, and how many (if we could but trace them) are infected with the poison deposited by preceding cases in the sewers? Typhoid has been prevailing to a marked extent in this city. During the past four months there were reported 527 cases. These cases were thoroughly investigated by the Board of Health, with a view to discovering the source of infection. The milk and water supply were carefully inquired into without revealing anything suspicious, but out of 462 instances where the premises were inspected sanitary defects were found in 324 or seventy per cent. In how many of these cases was the poison cultivated in the drains, as in the experiments of Pasteur and Koch, from the produce of a previous case, and allowed to enter the apartments along with the gases of the sewer? Whatever this number is, just so many could have been prevented if the poison had been destroyed when generated.

The danger of allowing the discharges to be thrown without disinfection into the sewers may be understood from the following facts: During the past year the Board of Health, following its usual custom, examined a large number of houses in eleven different sections of the city, and occupied by all classes of the community. The examinations are made without any previous knowledge of the sanitary conditions of the houses: —

The total number examined was 491.

The number in which bad odors were found was 332.

The number in which defective drains were found was 279.

The number in which defective trapping was found was 210.

The number having offensive privy vaults was 72.

The number having offensive water-closets was 50;

While those having ventilation to the soil pipe or drain *was only* 40.

The danger from the pollution of well water in country towns may be appreciated from Mr. Ernest W. Bowditch's report on The Sanitary Condition of Nahant. After the epidemic of typhoid in that town in the summer of 1881 all, or nearly all, the wells in the town were submitted to chemical examination. Out of 190 wells examined 79 or forty-one and one half per cent. were considered to be desirable waters, while 111 or *fifty eight and one half per cent. were found to be so polluted as to be dangerous for use.*

There is no reason to suppose that the wells of other towns are in any better condition than were those of Nahant. On the contrary, Mr. Bowditch truly remarks, "the character and intelligence of a majority of the citizens and visitors preclude the possibility of the intentional omission of any sanitary care that could be considered necessary, either on individual estates or in the town as a whole, and yet here in the midst of wealth and intelligence some of the grossest instances of careless-ness, as regards the simplest sanitary matters, that can be conceived of have come to light." There can be no doubt that throughout the State are thousands of wells in a dangerous condition, polluted daily with the drainage from privies and sewers, and only awaiting the time when the germs of typhoid shall be carried into them to serve as cultivators and distributors of fever.

It has been calculated that there are 10,000 persons sick with typhoid every year in this State alone. In England Dr. Budd, as far back as 1859, calculated the number to be from 100,000 to 150,000, and Dr. Maclagan, in 1879, at 200,000. In other words, however unpoetical it may sound, we have in this State an army of 10,000 intestines discharging daily for a number of weeks each year a most virulent poison into the outer world. Is it any wonder, then, that we cannot follow each germ in its wanderings over the land, or trace back every case of fever to the germ which took root in its soil!

To what extent our total of infected cases would be swelled could we count the number of endemic cases which would be found to have their source of infection in previous cases, were efforts directed to that end, it is not in our power to say, but to an unprejudiced mind there can be no doubt that the figures would be alarming. That it is possible by proper methods of disinfection to prevent the occurrence of a large proportion of such cases is no Utopian idea, nor one that passes the bounds of probabilities.

A commission appointed by the city government in 1875 to investigate the sanitary condition of Boston,

[1] Concluded from page 175.

and composed of such men as Dr. Calvin Ellis, Dr. R. M. Hodges, Dr. Samuel Green, and the late Drs. Buckingham and Curtis, in its report declared that "our first line of defense against the spread of typhoid fever from a diseased individual consists in the proper treatment of the dejections, which are held to contain the seeds of the disease. . . . The dejections should, if possible, be rendered harmless before being thrown into the privy, and so being allowed to mingle with sewage."

The *British Medical Journal*, the leading representative of medical opinion in England, declared in a recent editorial that typhoid fever was a preventable disease, and in its epidemic form could be entirely suppressed, and could be limited to a comparatively insignificant number of sporadic cases.

Dr. Budd, over twenty-five years ago, maintained the possibility of stamping out typhoid fever, and laid down rules for observance. But Budd, to whom the credit is due of being the first to demonstrate the communicability of the fever, went farther, and claimed that every case was due to infection from a preëxisting one, and no case ever arose *de novo*. While I am at present unprepared to follow him and other eminent authorities thus far, I think there can be little doubt as to the infectious origin of a large number of cases, and if it be true, as is among the possibilities, however unsubstantiated to-day, that no case arises spontaneously, but only from some preceding case, the number of preventable cases is greatly increased, and it is not entering the realms of imagination to say that typhoid fever may eventually be reduced to a comparatively small number of sporadic cases.

Dr. Gage, in his annual address before the Massachusetts Medical Society, estimated the number of cases which occurred in Massachusetts alone between the years 1840 and 1880 in round numbers at 390,000; of these *about* 40,000 perished. As this writer says, "these are startling figures."

After a consideration of the above facts it seems to me that the conclusion is justifiable that a large proportion of these cases could have been prevented if proper precautions had been taken; or, if this be doubted, it still must be conceded by the most skeptical that the evidence is sufficiently strong to justify any reasonable means to attain this end.

I now come to the main purpose of this paper, What is the remedy for the future? I believe it is alone to be found *in legal enactments through State and local boards of health. It should be compulsory for every householder in whose dwelling a case of typhoid occurs to see that the dejections are disinfected with proper and prescribed means*, and to this end every case of typhoid should be reported to the proper local officers, who should furnish, at the public expense if necessary, efficient chemicals, such as sulphate of iron, for this purpose.

Disinfection cannot be left to the physician alone, even supposing that he can be reasonably called upon for this duty. There are many factors on his part which would, and do, operate to prevent such a measure from being carried out. Universal skepticism, with which some are endowed, as well as the general frailties of human nature, where demands are made on the time and labor of the busy practitioner, would play their part. There is also a general tendency with the physician to "take the chances," as he himself is so often obliged to do, when called upon to expose himself to contagion. On the other hand it is absolutely useless for any board of health, however able and efficient, to attempt to enforce thorough disinfection — and if not thorough it is useless — unless supported by the public sentiment of the profession and of the community at large, and aided by the willing coöperation of both. But for the enforcement of such regulations, as I have advocated in this paper, something more is necessary than the mere passing of laws. There would be required a more extensive sanitary machinery than that which we now have. It seems to me that the present statutes regarding the establishment of boards of health and health officers are too general and lax. If any town does not choose to take advantage of them their effect is void. Furthermore, by allowing the selectmen of towns to act as boards of health the benefit of experts is lost. It is to be feared that the knowledge of the average selectman in matters pertaining to sanitary science is somewhat similar to that of the famous Pickwickian character who "had a vast variety of opinions on a vast variety of subjects." It is difficult to ascertain the number of cities and towns in the Commonwealth which have regularly appointed boards or medical officers. But from information obtained at the State Board of Health and elsewhere *sixty only out of three hundred and forty-one towns* would be a fair estimate. This shows how inefficient are the existing statutes, and how necessary it is that some radical measures should be adopted in order that the object may be accomplished for which they were framed.

In the present arrangement there is lacking that general centralization which is necessary for unity of system and action. Thoroughness and efficiency can only be obtained by having similar methods of investigation and common sanitary regulations for every town.

It seems to me that some such scheme as the following is requisite. There should be a central State Board of Health, which should be yoked neither with the goddess of charity on the one hand nor of lunacy on the other. The present triple-headed monster, from which, being hybrid by nature, only sterility can be expected, should be abolished. Then every town of, say, three thousand inhabitants which possesses no local board of health should be obliged to appoint medical health officers. The remainder of the smaller towns, unless they also elect to appoint such officers, should then be grouped in districts, for each of which similar officers should be appointed. Connected with the central State Board should be sanitary inspectors, who should be medical men. Whenever a case of typhoid or other contagious disease occurs it should be reported to the local boards of health, or medical officers, who should investigate the case with a view to discovering the focus of infection. The investigation should be conducted upon a general systematic plan, established by the central board, and should always include the milk, water, food, air, drainage, habits of the people, late whereabouts, etc., etc.

If the case is one of typhoid the medical officers should see that the family in which the case occurs properly disinfects the discharges, and if the circumstances are such as to warrant it the disinfectants should be furnished at the public expense. Other diseases should be treated according to recognized sanitary requirements. The local boards of health of cities should be independent of all central authority. Whenever any extensive epidemic occurs in any part of the State, one of the State sanitary inspectors should be

sent to aid in the investigation, and the results should be publicly reported. With some such machinery as this I believe that not only would our knowledge of the ætiology of disease and the conditions of contagion be greatly enhanced, but a vast amount of sickness be prevented.

It will probably be said in objection that the time is not yet ripe for disinfection to be compulsory, and without the coöperation of the community it would be impracticable to enforce the laws. If such be the case it is not because the laws of hygiene are not sufficiently determined, but because the community has not been educated up to the present standard of sanitary science. And it is here that the medical profession should be the leader and educator of public opinion. If we are convinced of the necessity of sanitary reform, and of the enforcement of regulations for the protection of health, we should, by continued agitation and public expression, instruct the public in the laws of sanitary science, and give warning of the dangers to which it is exposed. It is to the medical profession that the public looks for guidance in these matters, and the profession should give forth no uncertain sound. It seems to me that the public can in no better way be informed of the dangers to health and of the necessity of employing proper precautions for the prevention of contagion than by some such measure as I have ventured to propose. It seems to me that its moral force alone would be incalculable, and that it would be the very best method of educating the people in sanitary matters. But it would of course require time to be thoroughly and efficiently put into operation. That it would eventually succeed I think there can be little doubt. We must remember that a large proportion of the community is ready to-day to do anything for the preservation of its health. It only waits to be assured of the reality of the dangers and of the utility of prophylactic measures.

The cost of the measures just advocated would be small, so small as to justify them on experimental grounds alone. How shortsighted seems the public policy which expends thousands, nay millions, of dollars throughout the Commonwealth to secure perfect systems of drainage while the very fountain-head of one poison, at least, is allowed to flow on, and to be carried whither chance may direct. However desirable a good system of sewerage may be, it is certainly more philosophical to destroy the very poison at its birth rather than to depend alone upon the soundness of conductors to take it away. Traps will leak, and drains will get out of order, no matter how thoroughly the work be done. And as long as this is the case, and as long as the dejections of typhoid patients are thrown without disinfection into the sewers the poison will propagate itself, and typhoid will continue with undiminished virulence.

A CASE OF CONGENITAL MALFORMATION OF THE GENITAL ORGANS.[1]

BY E. F. CUMMINGS, M. D.

On the 8th of September, 1880, an infant, apparently about three months old, was found in the city, abandoned by its parents, and was taken to the temporary home on Chardon Street. It was subsequently taken in charge by the Superintendent of Out-Door Poor, whose duty it is to provide for such children, and the medical care of it devolved upon me from that time until its death, September 11, 1882.

On examination the child was found to be healthy and normally developed, with the exception of the genital organs; these were malformed to that extent that it was impossible to accurately determine its sex, although my own opinion was that it was a case of hypospadias.

The infant was sent to board with a family in the country, and I saw it frequently during the two years in which it was under my care. The child was generally healthy, having fewer infantile troubles than the majority of children who are artificially brought up. There was no disorder in which the cause was traceable to the malformation, but in one instance, and that was an attack of acute cystitis, when the child was about eighteen months old, due to a constriction of the urethra, spasmodic in character, and a consequent retention of the urine. When my attention was first called to this difficulty, I found the patient passed but a small amount of urine at a time, and the act appeared to give rise to considerable pain. The urine was loaded with pus, and by pressure over the bladder pus could be squeezed out from the urethral opening.

At first but a very small bougie could be passed through the urethra, but by gradual dilatation it was enlarged sufficiently to admit of a double catheter. The bladder was then washed out with a weak solution of carbolic acid. This treatment was continued twice a day, the symptoms began to subside very soon, and in two weeks the patient recovered entirely from the attack and had no further trouble of the sort.

The child's death was caused by acute enteritis with convulsions. As the last sickness had no connection with the malformation as far as could be ascertained, I shall not enter into it in detail.

The child appeared to have more than ordinary intelligence, was affectionate, and, if we accept the evidence of the members of the family in which it was boarded, it was really quite a paragon of excellence. They became so much attached to it that they had the body buried in their own lot, and mourned for it as much as they would for one of their own offspring.

Shortly after the infant came under the care of the State the mother was found; but as she was unable to properly care for it she was glad to let it remain where it was. On questioning her she admitted that she was probably intoxicated at the time of the connection which resulted in conception. She was a married woman, and had had one other child, which was then living; but her husband was not the father of this one. As far as she knew there had never been any abnormal development in any of the members of her family.

In a few days after the body was buried I had it disinterred, and, although decomposition had begun, with the assistance of Mr. Walter Carl, of the class of 1883 in the Harvard Medical School, succeeded in getting a pretty good cast of the external genital organs; he also made a drawing of the parts as they appeared at that time, both of which I will pass around.

Before the autopsy several physicians saw the body, and expressed the opinion that it was a case of hypospadias.

A good idea of the external genital organs can be gotten from the cast and drawing. There is what appears to be a bifid scrotum, with well-marked rugæ, a

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, January 10, 1883.

penis of perhaps half the normal size, with a distinct glans, but no urethral opening in it. The latter is found at the base of the penis or enlarged clitoris.

The outward appearance is certainly indicative of a male child. I first made an incision into the supposed scrotum, but on dissecting found no testicle. I found, however, what I supposed to be the spermatic cord, and followed its course through the external and internal ring into the abdomen. On opening the abdomen I was surprised to find a uterus of fully the ordinary size in a child of that age, and what I supposed to be the spermatic cord was attached to the body of the uterus, and proved to be the round ligament. The walls of the uterus were thin, and the cavity, which as you will see if you examine the organ, was very much distended, was two thirds full of a viscid substance resembling lymph in appearance. There is no distinct cervix as is seen in the normal organ, and an entire absence of a vagina.

What corresponds to the os uteri is an orifice large enough to admit of an ordinary sized probe, opening into the urethra about one fourth of the distance from the neck of the bladder to the urethral opening.

The appendages of the uterus are all present, — the Fallopian tubes, the ovaries and their ligaments, and the round ligament. The ovaries, however, are misshapen, being long and narrow, and situated higher up in the broad ligament than normal.

To sum up the features of especial interest in this case, we have a malformation confined to the organs of generation; the external organs presenting more the appearance of belonging to a male than a female. The penis or enormously enlarged clitoris, the bifid scrotum or a phenomenon having the appearance of such, and the urethral opening, — all of these favor the supposition that the child was a male. On the other hand, the internal organs, the uterus and its appendages, prove conclusively that it was a female. In view of the fact, however, that the external genital organs bore such a resemblance to those of a male, I think it is safe to class this case with the so-called hermaphrodites.

I shall not enter into the cause of this malformation, as I have not studied the subject sufficiently to do it justice. If you will allow me, however, I will give you the opinion of a non-medical man, the officer who found the mother of the child after she had deserted it. On questioning her he found that the act of coition, which probably resulted in conception, was performed in a house that stood on the line between the States of Maine and New Hampshire. From this fact he argued that it was not strange that the condition of the child should be such as we found it.

A CASE OF POISONING WITH ILLUMINATING GAS.[1]

BY A. L. MASON, M. D.

A MAN apparently in the prime of life went to one of the smaller hotels in the city early in the forenoon of September 19, 1882, engaged a room, and soon retired. In the evening he was found unconscious, being supposed to have blown out the gas, and was brought by the police to the hospital in a comatose condition. The pupils were equal, contracted, and at first irresponsive to light. There was no cyanosis. The breathing was 50 to the minute and shallow. The pulse was 120 and weak. There were abundant râles in the chest. The temperature was 100.2° F. Three pints of urine, which smelt strongly of gas, were drawn by catheter. An ice cap was placed on his head, and as he could not be made to swallow, an ounce of whiskey was given every two hours by rectum.

The next morning the temperature was 104° F., pulse 132, respirations 65, and he appeared to be failing. Two pints and a half of gas-smelling urine were obtained by catheter. The bowels were evacuated, and nutritive enemata were ordered. At noon the rectal temperature was 105.8° F., and he was sponged with ice water for an hour, under which the breathing became slower, the temperature fell to 102° F., and the pulse improved. There were also reflex movements of the legs and yawning. After the bath there was some tremor, and a partial return of the previous condition. He was given hypodermic injections of brandy. In the evening the temperature rose to 104.5° F., pulse 180, respirations 52. The cold sponge bath was repeated, reducing the temperature to 103.2° F., and the pulse and breathing improved. After the bath, however, there was the same return as before to the previous condition, and the hypodermic injections of brandy were repeated. He was catheterized regularly.

The next morning, thirty-six hours after admission, the temperature was 102° F., pulse 190, respirations 40. He was given thirty grains of quinia sulphate by rectum, and bathed occasionally with cool water. The temperature, pulse, and respirations fell during the day, to rise again moderately in the evening, and the baths were omitted.

The next morning (third day) the temperature was 103° F., pulse 150, respirations 48, and the baths were resumed. Physical examination, which had been found very difficult on account of the shallow respiration and general condition, detected coarse moist râles in the right side and back, and loud friction sounds in the left side and front.

There was the usual evening exacerbation of the fever, but the next morning (fourth day) the temperature fell to 99.2° F., pulse 115, respirations 38. The right pupil was larger than the left. He was rapidly failing, and died in the course of that day, the fourth after entrance. The urine showed nothing beyond a trace of albumen.

At the autopsy, twenty-three hours after death, by Drs. Johnson and Clarke, there was found a recent fibrinous pleurisy on both sides of the chest, with about two hundred cubic centimetres of a puriform fluid in the left pleural cavity. The upper lobe of the right lung was solidified by an acute fibrinous pneumonia in the stage of gray hepatization.

This case is reported to the Society as being one of rare occurrence in this community, and is interesting as showing the complications which appear to have prevented recovery even after a lapse of time which would seem to have been sufficient for the elimination of the poison.

Of the various gases of which illuminating gas is composed carbonic oxide is mainly responsible for the poisonous effects, which are analogous to those produced by the vapors of charcoal, in France so ready and frequent a suicidal agent. Physiological researches have established the fact that carbonic oxide displaces oxygen from the blood and enters into combination

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, January 10, 1883.

with the coloring matter so that no more oxygen can be absorbed. Both the arterial and the venous blood may be of a bright cherry-red color, and this compound of carbonic oxide and hæmoglobin is not easily eliminated. Therefore its action is to be regarded as that of an irritant narcotic poison, with a special action on the nervous centres and the respiratory organs, independently of the suffocation which is due to want of oxygen. The inhalation of oxygen would seem to be indicated as a therapeutic measure, and in a number of recorded instances the transfusion of healthy blood has resulted successfully after the withdrawal of a certain portion of the contaminated fluid.

The elimination seems to be largely through the kidneys, as was shown in this case by the free secretion of urine, and its strong gaseous odor. Diabetes, mellitus, and albuminuria are frequent accompaniments.

A similar case was recorded by Dr. F. W. Draper in the last volume of City Hospital Reports, page 100.

RECENT PROGRESS IN THE TREATMENT OF THORACIC DISEASES.

BY F. I. KNIGHT, M. D.

ARGUMENTS IN FAVOR OF THE THEORY OF DILATATION OF THE HEART AS THE CAUSE OF CARDIAC HÆMIC MURMURS, AND OF THE APPENDIX OF THE LEFT AURICLE BEING THE PRIMARY SEAT OF THIS MURMUR.

DR. GEORGE W. BALFOUR read an interesting communication on this subject before two societies last summer.[1] He has been led to adopt the theory of dilatation of the heart as the cause of cardiac, hæmic, or chlorotic murmurs, (1) *because it seems to be the only one capable of reconciling the various discrepant hypotheses regarding the origin of these murmurs.* This theory is fraught with most important instruction on the one hand, and with a no less momentous warning on the other; because if it be true there is no longer any real distinction between functional and organic murmurs, and a murmur can only be regarded as functional when it is found to have been curable. Moreover, if functional (chlorotic) murmurs are really due to dilatation, as these murmurs are known to disappear in by far the larger number of cases, we thus obtain the important generalization that dilatation of the heart is a curable disease. The aortic orifice is the classic position of the hæmic murmur, but this hypothesis is totally at variance with the now well-known fact that the hæmic murmur at its first appearance, though it is a basic murmur, is not propagated along the aorta or into the carotids, and has its maximum intensity in the neighborhood of the pulmonary artery. On the other hand, Marchall Hughes's idea that the pulmonary artery is itself the seat of the murmur is untenable, because there is no possible cause of murmur in the pulmonary artery in such cases which is not equally operative at the aortic orifice, or, indeed, more so; while the universally recognized basic position of the primary hæmic murmur completely excludes Parrot's theory that it originates at the tricuspid orifice. Stokes is the only British authority who recognizes the possibility of the hæmic murmur being occasionally mitral in position. Thus we have each of the four orifices of the heart described in turn by most competent authority as the point of origin of the hæmic murmur, and each of them discarded as incompetent because inconsistent with actual facts in individual cases. Considering the unanimity which prevails amongst all cardiac authorities in regard to organic murmurs, there can be but one explanation of this extraordinary discrepancy as to the hæmic murmur, and that is that it is a murmur which may be audible in all the various positions described.

(2.) The theory of cardiac dilatation, as the cause of the hæmic murmur, is thoroughly *consistent with the results obtained by experimental investigation.* When the late Dr. Marshall Hall was engaged in investigating the effects of the loss of blood upon the system, he observed that during the reaction subsequent to such loss the action of the heart was "accompanied by a peculiar noise resembling that of the saw or of the file, termed by the French *bruissement*, and very discernible on applying the ear to the chest." This *bruissement* Marshall Hall distinctly recognized as identical with the chlorotic murmur, and he accepted its artificial production by loss of blood as a clear proof of the purely hæmic character of the murmur.

(3.) The theory of hæmic murmurs being due to cardiac dilatation is *perfectly consonant with clinical experience.* Wunderlich and Friedreich have described the chlorotic heart as dilated; while Beau, Bamberger, and Stark have adopted the more rational view that it is hypertrophied as well as dilated; and so well established does this view seem now to be, that Dr. Heitler, of Vienna, one of the most recent writers on cardiac disease, speaks of the dilated hypertrophy of the heart as a well-known and acknowledged fact. As the heart dilates the mitral and tricuspid valves become incompetent, and the resulting regurgitation gives rise to murmurs. The regurgitation through the tricuspid produces undulations in the jugular veins, and the abnormally large ventricular blood-waves, coupled with the abnormal friction of the spanæmic blood at the arterial orifices, give rise to systolic murmurs in the aortic and pulmonary areas, which are also propagated along the carotids, and may be heard on the slightest compression in every artery in the body.

Thus in advanced chlorosis we have murmurs in every cardiac area — the earliest indication of any lesion of the heart being an accentuated pulmonary second, due to loss of tone of the left ventricle. Dr. Balfour is sure that all agree with Hayden that the primary cardiac hæmic murmur is basic; that it is not prolonged in any special direction, but radiates round the pulmonary area, in the neighborhood of which its position of maximum intensity lies. It has already been pointed out that there are in chlorosis no causes of murmur operative at the pulmonary orifice which are not at least as active at the aortic opening, so that a pulmonary murmur would certainly be accompanied by an aortic murmur also, and the latter would, of course, be propagated along the course of the aorta, and more or less distinctly into the carotids. This primary murmur cannot, therefore, be pulmonary; and, indeed, on careful examination, its position of maximum intensity is found not to be over the pulmonary artery at all, but from one to two inches to the left of the sternum, in the second interspace. In this position this murmur is to be detected at its

[1] Edinburgh Medical Journal, October, 1882.

very earliest appearance, quite to the outside of the pulmonary artery; here, too, Dr. Balfour rarely fails to detect, at least during expiration, some faint pulsation.

A basic systolic murmur, occupying precisely the position of the primary chlorotic murmur, is not unknown in other forms of cardiac dilatation, and it has been long recognized as of common occurrence in cases of mitral stenosis, in which also a pulsation in the second left interspace, due to the appendix of the left auricle, is of no infrequent occurrence. Naunyn proved that this depended upon mitral regurgitation.[1] The fluid veins formed at the mitral orifice impinge upon the tense auricular wall and throw it into sonorous vibrations, which are conveyed to the chest wall by the appendix of the left auricle, which lies in contact with it at the base of the heart. Naunyn's views have been accepted by all recent authorities. The basic position and auricular character of a mitral regurgitant murmur in certain cases is therefore an acknowledged fact. That the primary cardiac hæmic murmur has a similar origin seems to be proved by these facts: (1.) In chlorosis the heart is dilated and hypertrophied, and the primary murmurs are certainly not arterial in character. (2.) The position of maximum intensity of the primary hæmic murmur and of Naunyn's murmur is precisely the same; and (3) the graphic record of the pulsation in both classes of cases is similar, and as it is known to be auricular in the one it is most probably auricular in the other also, especially as it is certainly neither ventricular nor belonging to the conus arteriosus. The dilated condition of the heart, even in the very earliest stages of chlorosis, is to be inferred from the apex-beat being either entirely absent or only faintly perceptible, not in the usual position but just beneath the lower part of the sternum. This is due to the dilatation of the right ventricle, which dilates *pari passu* with the left ventricle, and, like a water-cushion, separates it from the chest wall, leaving the dilated appendix of the left auricle the only part of the left side of the heart in contact with the chest wall. The peculiar position of the primary hæmic murmur is no doubt largely, if not wholly, due to this. Shortly after the appearance of the primary hæmic murmur a tricuspid murmur and jugular undulation are found to be developed. This is naturally accompanied by a pulmonary and also by an aortic systolic murmur, the active cause in the production of both these murmurs being the large blood-waves sent on by the dilated and hypertrophied ventricles. The aortic murmur is, of course, propagated into the carotid arteries. About the same time we also have a systolic murmur in the mitral area; but this is probably due to the right ventricle being now so dilated that its apex occupies the position of the left apex in health. It is only rarely, and chiefly in a peculiar class of cases, that we have an opportunity of watching the gradual development of the hæmic murmur from area to area, but we all have frequent enough opportunities of tracing the involution of this murmur; and, if carefully observed, it will be found to die off precisely in the reverse order to that which I have described, the venous hum being the last to disappear.

With a short auricular appendix it is, of course, quite possible that the primary hæmic murmur may be pulmonary, or aortic, or even tricuspid in character. But, though such a state of things is undoubtedly possible, it must be extremely rare. Dr. Balfour has not seen such, his argument being that the cardiac murmurs of chlorosis are formed in a dilated and hypertrophied heart, and that the primary position of the murmur is in by far the larger proportion of cases, if not in all, to be found over the left auricular appendix, where it comes up from behind, just to the left of the pulmonary artery.[2]

A SUBSTITUTE FOR DIGITALIS. THE CONVALLARIA MAJALIS.

Dr. E. P. Hurd[3] calls attention to this drug, reproducing portions of Germain Sée's article, which appeared in the *Bulletin General de Thèrapeutique* for July 30, 1882. This plant, commonly known as "lily of the valley," has been regarded as a remedy for dropsy by the peasants of Western Europe.

In 1880 two Russian physicians published results of treatment of cardiac dropsy with the convallaria. Professor Sée has recently experimented on animals and man with it. A drop of the extract of the flowers brought in contact with the naked heart of the frog arrests the action of that organ in about two minutes. The result is obtained by injection under the skin. In a dog four drops of the extract injected into a vein caused death in ten minutes. The heart is first slowed and the respirations quickened, then the heart's action becomes irregular and the pulsations faint and very rapid; the blood pressure first augments and then is lowered, the respirations become slower and slower, the heart's action ceases, pressure falling to zero, and the respiratory movements cease in their turn. The excito-motor power of the nerves and nerve-centres is unaffected. The excitability of the pneumogastrics is weakened, not destroyed. No diuretic effects were observed in the dog. Professor Sée administered the drug, usually half a gramme of the extract daily (in some cases increased to a gramme), to twenty cases of cardiac disease. In all but three there was decided improvement, as shown in the increased strength of the heart's action, increase of urine, disappearance of dropsy, or some other marked change properly attributable to the drug. In his conclusions Professor Sée says that convallaria increases the energy of the heart, and has a decided diuretic action ("the most powerful, the most constant, and most useful effect is the abundant diuresis"). It has no deleterious effect on the economy, and no cumulative action.

Dr. Hurd has employed a fluid extract in two cardiac cases, with benefit; in one a copious diuresis set in on the third day of its administration, the quantity of urine passed increasing from eight to sixty ounces.

Dr. A. H. Smith reported at a meeting of the New York Academy of Medicine,[4] a case of typhoid fever, in which, the pulse being imperceptible at the wrist, and the first sound of the heart scarcely audible, the hypodermic injection of the fluid extract of convallaria temporarily restored the radial pulse and distinctness of the heart sounds; also a case (seen in consultation) of peritonitis under the opium treatment, in which the patient suddenly went into a condition of collapse.

[2] For a fuller account of the position and mechanism of the hæmic murmur see London Lancet, September, 1867, page 383, and Balfour on Diseases of the Heart, etc., 2d edit., 1882, pages 84 and 137.

[3] New York Medical Record, September 9, 1882.

[4] New York Medical Record, December 9, 1882.

Caffein and atropia had been given, and the galvanic battery had been applied. The man was apparently dead. The battery was continued. Convallaria was used hypodermically. After the lapse of nearly half an hour the heart's action began to increase in strength and exceedingly shallow, infrequent respiration returned. Ultimately the patient was restored.

Dr. Beverly Robinson also reported at the same meeting that he had used the convallaria in cases of cardiac and renal dropsy with deficient heart power, with favorable results.

Dr. Henry L. Taylor [1] gives a full report of twenty cases treated with the convallaria, daily records of pulse, respiration, and quantity of urine being frequently given. The results seem satisfactory and warrant further trial of the drug as a substitute or alternate for digitalis. The dose used by Dr. Taylor was from ♏ v. t. d. to ♏ xx. q. 4 h. of the fluid extract of the flowers, and in two cases ʒi. t. d. was given with good results, where smaller dosage failed.

Dr. Beverly Robinson [2] reports a case of emphysema and asthma relieved in a remarkable degree by the convallaria.

Dr. Polk, in the same number of the *Record*, reports a case of vagus neurosis in which extremely rapid action of the heart was relieved by the convallaria. The heart was beating at the rate of 240 in the minute. The patient had already taken ten drops of digitalis. Dr. Polk gave him ten minims of the fluid extract of convallaria hypodermically, and one half an hour later repeated the dose. Five or ten minutes after this the pulse dropped to 120. It came down not gradually, but at once. The bad symptoms all disappeared in two hours.

See the JOURNAL of February 22, this year, for some evidence against the value of this drug.

CARDIAC SURGERY.

Our readers have recently had a paper on this subject from the pen of Dr. John B. Roberts,[3] who says that it is more than probable that, in a few years, puncture of the heart wall, with direct abstraction of blood by aspiration, will be recognized as the best treatment in cases of greatly dilated or much distended right heart, with intense pulmonary engorgement, etc.

Dr. C. L. Dana [4] reports two cases in which he aspirated the right ventricle with no effect. Dr. Dana does not consider puncture of the right ventricle a difficult or even very dangerous operation. He would not advise aspiration of the right auricle under any circumstances. Not because it is necessarily dangerous, but physiologists are agreed that the auricle is chiefly a regulator and reservoir, not a propelling muscle. Unloading it could have little effect on the work of the heart. Cardiac aspiration may be indicated in cases of sudden heart paralysis, when the ventricle is presumably over-distended. The needle may possibly relieve over-distention, and by its irritation set the heart to work again. In cases of laboring heart, however, Dr. Dana would vastly prefer venesection, whose potency is unquestionable.

In the same number of the *Record* the editor takes occasion to advise caution in surgical procedures in this region.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

SERVICE OF DR. SUMNER.

REPORTED BY DR. M. D. CLARKE, HOUSE PHYSICIAN.

TWO CASES OF INTESTINAL OBSTRUCTION. ONE FATAL. AUTOPSY.

I. —— ——, a married woman, thirty-seven years old, a native of Ireland, was admitted to the hospital June 15, 1882, on account of gastric disturbance. Six months previously she had begun to lose her appetite, and to feel distress and pain in the epigastric region after meals; and these symptoms gradually increased for five months, when vomiting was added to them. She had vomited every day for the five weeks just preceding entrance, usually two or three hours after taking food. The vomitus had consisted of the ingesta, once of "blackish water," never of blood or "coffee-ground" matter. There was a troublesome pyrosis. She felt hungry at the time of her admission. The pain in the epigastric region was severe enough to keep her awake nights. She had lost a great deal of flesh and strength. There was marked constipation. Beyond a cough of a year's standing, there were no other symptoms. The temperature was normal, the pulse 96.

The next day physical examination discovered nothing but tenderness in the epigastric region. There were paroxysms of pain accompanying visible paroxysmal contractions of the intestines, when it seemed to her that wind was forced up into her mouth. There had been a very slight dejection after an enema of two pints of soap-suds, preceded by half a pint of olive oil. She had retention of urine and required to be catheterized. She was ordered ten grains of bismuth subnitrate three times a day and put upon milk diet.

The next day three quarts of water were slowly injected into the rectum with a Davidson's syringe until some pain was occasioned. This was relieved when the water was discharged, but no fæces were passed. This was repeated the next day, when a slight dejection occurred. There was now discovered, about an inch and a half to the right of the umbilicus, a tumor, the size of a large hen's egg, rather elongated, its long axis parallel to the vertebral column. She looked brighter and felt better as the result of the last enema, had not vomited for forty-eight hours, and craved more food, which was given her in the shape of ice-cream.

From that time until she left the hospital, against advice, nearly a month after entrance, the history was one of progressive failure and emaciation. The constipation continued, but was less marked. The persistent vomiting compelled nourishment by the rectum, which was exchanged now and then for nourishment by the mouth, to be resumed in a few hours. The vomitus was examined a number of times microscopically, but with negative results. The tumor became rather more apparent. Beyond that there was no change in her condition. Nothing was found in the urine.

II. —— ——, a widow, forty-five years old, a native of Scotland, by occupation a cook, was admitted to the hospital May 27, 1882, with the diagnosis of dyspepsia, and discharged well a week later. She gave a history of vomiting for eight months previous, with severe pain during emesis; but there was no vomiting or pain while she was in the hospital.

Three weeks later she was readmitted. She had been well for two weeks, and then vomiting had returned. Two days before entrance she had vomited, she said, half a cupful of blood. Her temperature was normal; pulse 92. Nothing was detected by physical examination beyond tenderness in the epigastrium. She was ordered milk and lime-water, and given twenty grains of bismuth subnitrate three times a day. Constipation was present upon entrance and persisted, and no satisfactory movement of the bowels was obtained until ten days after entrance, after the injection of an ounce of olive oil every hour for six hours, followed by a large enema of soap-suds, containing half an ounce of spirits of turpentine. Two days later her condition was such as to need alcoholic stimulation, and at this time, on account of the persistent vomiting, she began to be fed by nutritive enemas, and a part of the time these were not retained. Hiccough was at this time a prominent symptom. For several days the vomitus was extremely offensive, consisting of stercoraceous matter. The general condition was very poor, and the patient's death was looked for. There was, however, no new physical sign except a little more resistance on the right than on the left side of the abdomen, and a slight œdema of the tissues in that neighborhood. After a few days she rallied, vomiting ceased, and she was again fed by the mouth.

The diagnosis had hitherto been supposed to rest between gastric cancer and ulcer, but a fæcal tumor, perhaps related to obstruction near the ileo-cœcal valve, now seemed possible. Before and after the period of collapse injections of water, as large as could be given without pain to the patient, were forced into the rectum, but only slight dejections followed. The faradic current was also employed, one pole in the rectum and the other moved over the abdomen, but without result. A little later, however, there began to occur moderately-sized, loose dejections, some of them clay-colored, and she was given fifteen grains of calomel, which was followed by a large, loose dejection. The abdomen was now tympanitic throughout, and there was distinct gurgling in the right iliac fossa. For a week or two there were six or eight movements of the bowels daily, the dejections consisting of liquid fæces. The patient sat up and felt much better, was able to eat ordinary diet, and was put upon tonics and malt liquors. The diagnosis of fæcal tumor seemed fairly confirmed. She remained in the hospital a month longer, suffering only from weakness, anorexia, occasional abdominal pain, and vomiting, which were attributed to gastric and intestinal indigestion; and she was sent to St. Luke's Home, in the belief that change of air and scene would be the best restorative.

After a residence of two weeks at St. Luke's, during which time she could retain little or no food and steadily failed, she was readmitted to the hospital, evidently dying. She complained only of abdominal pain, and there was nothing new observed but an aphthous condition of the mouth. She died in four days, diarrhœa being the only marked symptom. The urine was examined each time she was admitted, but with negative results, and nothing of moment was ever found in the vomitus.

At the autopsy, by Dr. Gannett, nine hours after death, there was found some pulmonary emphysema and a moderate atrophy of spleen and kidneys. The mucous membrane of the last thirty centimetres of the ileum, and that of the cæcum and ascending colon was much thickened and reddened, showing many irregular patches of loss of substance with ragged bases. The muscular coat was four times as thick as normal. At the hepatic flexure of the colon the lumen was so narrowed as to admit only a No. 18 French bougie. At this point the mucous membrane had entirely disappeared, the muscular coat was very much thickened, and outside of the latter there was much dense connective tissue. Beyond the constriction the mucous membrane was normal. The neighboring lymph glands were enlarged, dense, grayish-yellow upon section.

III. TYPHOID FEVER. THROMBOSIS. DEATH.

—— ——, a married man, twenty-five years of age, born in Massachusetts, by occupation a teamster, was admitted to the hospital July 26, 1882, complaining only of headache. He asserted that he had been sick but four days, but his dry, cracked, and swollen tongue, marked stupidity, and general condition contradicted him. No farther history was to be obtained. Temperature 102.8° F.; pulse 92. He was given two grains of quinia sulphate three times a day, and ordered to be sponged with cool water every two hours while the temperature remained above 102° F.

The diagnosis of typhoid fever, which the appearance of the patient suggested, was confirmed in a day or two by the appearance of rose spots and the presence of tenderness in the right iliac fossa. Examination of the chest discovered bronchitis. A more active delirium set in. He was given whiskey in moderation.

During the fourth night after admission the signs of a profuse intestinal hæmorrhage were discovered in the bed, but the bleeding had then ceased. The pulse was rapid, small, and fluttering. He was given ten grains of gallic acid by mouth, and five grains of ammonium carbonate and a quarter of a grain of morphia sulphate by hypodermic injection, after which he went to sleep, and there was no farther hæmorrhage. The sponge baths were omitted, and the whiskey was increased. The day but one afterwards he had a chill, and in the afternoon the right arm was found to be powerless, hot, and swollen from the shoulder to the wrist; the hand and fingers were cool. There were purple patches on the fore-arm and upper arm, bright red spots on the former, which was also emphysematous in places. Extension of fore-arm caused pain. The brachial and radial pulse was absent. The temperature was 105° F.; the pulse too rapid to count. Death occurred a few hours later.

IV. PYOPNEUMOTHORAX. DEATH. AUTOPSY.

—— ——, a married man, twenty-four years old, an American, a gilder by trade, was admitted to the hospital August 26, 1882. The family history was good. He had been well until the previous February, when he began to have a cough. The next month he had hæmoptysis, night sweating came on, he lost flesh and strength, and lately had been troubled with dyspnœa and palpitation. His appetite, however, was fair; he had no diarrhœa, and micturition was normal.

Upon examination the next day there was found, when he sat up, diminished respiration over the whole right chest, growing fainter towards the base, and absent behind, from two inches below the angle of the scapula. From the angle downwards the vocal resonance was diminished, growing fainter towards the base; in this region there were metallic tinkling, dull-

ness, and absence of vocal fremitus. When he lay down the whole right chest in front was resonant, the tone being higher in pitch than normal. Hepatic dullness and flatness were nearly absent. Respiration was diminished. In the upper third there were absence of vocal resonance and fremitus, and metallic tinkling. The intercostal spaces on the right side were obliterated. There were marked friction râles over the lower half of the left side in front; dullness, increased vocal resonance, and fine moist râles at the left apex. The area of cardiac dullness began two inches and a half to the left of the median line. The apex beat was felt in the sixth interspace, one inch outside of the linea mammalis. There was marked visible pulsation over the whole cardiac area. A systolic murmur was heard at the apex, and there was a thrill upon palpation.

He was put upon tonics, extract of malt, and whiskey, and for ten days appeared to be slowly improving, being troubled by little but cough and sleeplessness. At the end of that time he slept better, felt much better, and was up and dressed most of the day. The next morning he died suddenly in bed after a coughing fit. Nothing unusual was found in the urine. The temperature, which was normal upon entrance, fluctuated considerably, but rose no higher than 103.2.° The pulse never went above 120.

The autopsy was made about forty-eight hours after death, at the man's residence, by Dr. Clarke. The right pleural cavity, upon puncture, emitted a quantity of somewhat offensive gas. The cavity was filled with thick, laudable pus, and was distended so that it reached beyond the median line and pushed to the left the pericardium and its contents. The right lung, whose pleural surface was covered with a fresh fibrinous false membrane, was dense, retracted, and pressed close against the vertebral column. Its cut surface was covered with tubercles. The apex of the left lung was dense, and its cut surface also covered with tubercles. There was incompetency of the mitral valve.

V. TUBERCULAR PERITONITIS AND MENINGITIS. DEATH. AUTOPSY.

(*Dr. A. L. Mason on duty.*)

—— ——, a single man, twenty-four years old, a native of England, by occupation a book-keeper, was brought to the hospital in a comatose state September 21, 1882. It was learned from his friends that his parents died of consumption, and that he had not been considered as strong as his brothers and sisters. He had been in this country a year, and had not been well for some time, though he had kept at work as usual. Two weeks before entrance he had begun to complain of severe headache, general pain, and anorexia. He spent most of the time lying, dressed, upon a sofa, and did not take to his bed until the day before admission. He was at that time delirious.

When seen his temperature was 100.5° F.; pulse 75, regular, and of fair strength. Attempts to rouse him were vain, and he could not be made to swallow. He had to be tied to keep him in bed. The pupils were equal, slightly contracted, responsive to light. The other reflexes were normal. There was no paralysis. The tongue was moist, but he could not be got to protrude it. Physical examination of the chest gave a negative result. There was apparent tenderness in the right iliac fossa, but no rose spots or splenic tumor. There was retention of urine, for which catheterization was ordered. Slight albuminuria was present, but the microscope found nothing unusual in the sediment. An ice-cap was placed on his head, and he was given nutritive enemata.

The next day some convulsive twitchings were noticed. A stimulating enema was given without result. In the afternoon the left pupil was found dilated and much larger than the right, and the head was turned to the left. Ten grains of calomel were laid upon the tongue, and this was followed by a free movement of the bowels.

During the night he swallowed nearly a quart of milk, and the next morning appeared much better, though he would not talk or put out his tongue. The pupils were normal, but there was ptosis of the left eyelid. The nutritive enemata were discontinued.

The next day he was able to talk and answer questions. There was alternating strabismus. The abdomen was distended and painful. The urine was passed involuntarily. The nurse had noticed some tenderness at the back of the neck. During the next night he was so restless as to require a subcutaneous injection of morphia. The next morning the abdominal distention and tympanites had increased. Carphologia was present. He was freely stimulated, but during the forenoon became cyanosed, moist râles were heard throughout his chest, and death occurred in a few hours. The temperature never rose above 102° F., nor the pulse above 100.

The autopsy, by Drs. Johnson and Clarke, four hours after death, found the peritoneal surface of the diaphragm, that of the right abdominal wall, and part of that of the small intestine covered with tubercles. Tubercles were found in the omentum also. The lower part of the ileum was congested, and its external surface covered with a false membrane. There was a large amount of reddish fluid at the base of the brain and in the left lateral ventricle. There were two small, opaque, thickened patches in the pia mater at the base. The fissures of Sylvius on both sides were partially obliterated by old adhesions. The walls of the left lateral ventricle were roughened, and in one part covered with tubercles.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M. D., SECRETARY.

JANUARY 10, 1883. Meeting called to order at 8.15. DR. GEORGE B. SHATTUCK in the chair.

DR. E. F. CUMMINGS read a paper[1] on

A CASE OF CONGENITAL MALFORMATION OF THE GENITAL ORGANS.

DR. GANNETT mentioned some of the anatomical peculiarities grouped under the term of hermaphrodism, and said further that he thought the present case did not come under that head. The internal generative organs were evidently those of a female, and it seemed to him that the appearances presented by the external genitals might readily be explained on the supposition of an atresia of the vagina and a hyper-

[1] Vide page 195, this number of the JOURNAL.

trophy of the clitoris. Hence he would consider the individual to be a female.

Dr. David Hunt exhibited a sketch of the development of the generative organs in each sex at an early embryonic date, and observed that at such a period it was absolutely impossible to determine the sex, or to detect any difference between the sexes. (Kölliker, His, and Waldeyer.)

Dr. Blodgett said that the present specimen recalled a very interesting case he saw in Berlin, which was exhibited and described by Professor Virchow in 1872. The individual was about fifty years old, tall in stature, strongly built, having broad, massive shoulders, and probably weighed about one hundred and ninety pounds. The general health was good, and no physical distress or discomfort was known to be occasioned by the malformation. The right side of the face was larger than the left, the skin brawny and dense; the lower part of the face produced a coarse, stiff beard, and was regularly shaven. The right eye was farther removed from the median line than the left, the palpebral opening larger than that of the opposite organ, and the globe of the eye apparently of a greater diameter than that of the left side. The left side of the face was comparatively soft and smooth, the growth of beard was scarcely noticeable, the skin was not brawny nor thickened, and had a soft, feminine feeling. The left eye was apparently smaller than the right, the palpebral opening absolutely smaller, the distance of the organ from the median line not so great as that of the right. The breasts corresponded in every particular with those of a woman, and were very full, firm, and elastic, and covered with a delicate skin. The hips were no so broad as in a woman, but conformed more nearly with those of a man. The arrangement of the sexual apparatus was very interesting. In the normal position of the penis was found an organ about three inches in length, covered by a prepuce, and curved strongly downward. Upon elevating this organ it was observed that it was hypospadiac, and presented only a longitudinal groove upon the under surface. At a point immediately beneath this groove, at its proximal extremity, was observed the opening of the urinary meatus. Below this was located what seemed to be a scrotum, but examination revealed the fact that the organs of both sexes were present, the part upon the right side being a complete unilateral scrotal sac, containing a fully developed testicle with spermatic cord, while the portion upon the left side was a perfect external labium. The organs lay in juxtaposition, but were not united.

A catheter introduced into the urinary meatus, and passed gently along the floor of that canal, readily and easily entered the bladder, and urine flowed through it. Upon being withdrawn a short distance, and receiving an upward direction, the catheter entered another canal with more resistant walls and firmer structure, into which the instrument would pass but a short distance. The latter canal was considered to be the entrance to a uterus, communicating with the urethra by an opening anterior to the sphincter of the bladder.

In early life this individual had been married to a woman, and for four years occupied the relation of husband. No offspring was produced by this union, and at the end of this period a mutual separation took place. At one time the individual was in a hospital,[1] and while there was the subject of the closest investigation. During this period a natural menstruation occurred, which afterward reappeared at regular intervals while the patient was under observation. The fluid was examined and found to correspond in every known characteristic to the ordinary menstrual flow. It was also ascertained that seminal fluid was produced in this individual, which was ejaculated during orgasm, and which contained normal spermatozoa in a state of active motion. Thus it seems from repeated careful observation, aided by chemical and microscopical analysis, that the internal organs and functions of both the male and female organism are represented in the body of this strange individual.

[1] In Würtzburg, if I am not mistaken.

Dr. Cutler said the case spoken of by Dr. Blodgett he remembered perfectly as having been presented to the students at Berlin by Professor Virchow in the winter of 1872, though he had forgotten the details. Professor Virchow considered it, as Dr. Blodgett said, a case of hermaphrodism, and said substantially that this was the only case to his knowledge hitherto where the characteristics of true hermaphrodism had been traced so far as to require only the anatomical proof of the correctness of the conclusions.

The *Berliner klinische Wochenschrift* for 1872, No. 49, contains the account of the presentation of the case before the Berlin Medical Society, with a full description of the appearances, and the same case is translated and reported in full by Dr. Mundé in the *American Journal of Obstetrics*, vol. viii., p. 615, 1875.

Dr. Hunt thought that embryology favored the view that perfect hermaphrodism might occur. It is well known that for the first two months of embryonic life there is no distinction of sex; Müller's ducts and the Wolffian bodies and ducts exist in embryos of both sexes; when the sexual glands appear they cannot be distinguished as testicle and ovary; we have only to apply our knowledge of the pathology of the embryo to see that this condition of things makes perfect hermaphrodism a possibility. The process of development of the generative and urinary organs is well illustrated by the plate on page 340 of Henle's *Eingeweidelehre* and but slight additions have been made to the facts stated by Henle in describing the process.

Kölliker, after describing the development of the generative organs, in the last edition of his *Entwickelungsgeschichte*, says, "Hermaphroditic formations are striking in this connection, and particularly Scanzoni's case, where with well-formed male sexual organs there is a vagina opening into the pars prostatica urethræ, and a well-formed uterus and oviducts. It cannot surprise us to learn that there are cases, though seldom, where one sexual system is developed on one side and one on the other."

The case presented this evening appears to be one of deformity of the external genitals in a female.

Dr. Deblois asked if any microscopic examination of the organs found in the labia was made.

Dr. Cummings replied that Dr. Dwight examined them and found them to be ovaries.

Dr. G. B. Shattuck stated that whatever the external appearances of the individual case might be the determination of the sexual condition depended upon the presence of an ovary or testes. Cases possessing an ovary and a testis are exceedingly rare.

Dr. Draper said that the distinction of sex is based upon the functions possessed by the individual. He rather discredited the statements made by Dr. Blodgett, as to the existence of both generative functions in

one person; such a case he had never seen reported in medical literature. He thought that the only way of determining the real hermaphroditic character of an individual was the crucial one, in which the individual should beget offspring in a female, and should also bear offspring from impregnation by a male, thus demonstrating the existence of the double functions of the male and female sexual organism in the same individual.

Dr. Blodgett remarked that such a view of the subject appeared very strange and inconsistent. In the case he had described the presence of menstruation had been established by the careful investigations of trustworthy observers, who found its recurrent flow to correspond in every known characteristic to that of the ordinary fluid naturally eliminated at this time in all healthy, non-pregnant women. Thus far the presence of feminine organs and functions was established. The existence of seminal fluid had been proved, which was ejaculated during orgasm, and which contained active and apparently normal spermatozoa. The physical and anatomical conditions present in the case constitute an insurmountable hindrance to the occurrence of conception in the body of this particular individual, and probably also to the successful accomplishment of the sexual act with a female; but physically, chemically, and microscopically, the evidences of both male and female generative functions are indisputable, and there would seem to be no good reason to doubt that with more favorable structural and anatomical relations, both generative functions might be successfully performed by this or any similar individual.

Dr. Hunt stated that Kölliker had recognized the existence of hermaphrodism or *Zwitterbildungen* in the human subject, and that Scanzoni had seen and described the condition mentioned by Dr. Blodgett. The study of these curious freaks of nature was impeded because of defective knowledge of the primary anatomical formations, due to deficient teaching and lack of study of the embryonic development. The double organization of a hermaphrodite has its origin in some cause acting upon the transitional embryonic structures during the first three months of gestation, and it is well nigh useless to attempt to study the causes of such a malformation in an organism in which the organs have already reached their ultimate development, and the early relations and structures are entirely obliterated.

Dr. Shattuck asked Dr. Draper if any case had been reported in which menstruation existed, but in which there was no ovary.

Dr. Draper did not know. He mentioned the case of Levi Suydam, of Connecticut, who was considered to be a man, and conducted himself as such in every way, taking an active part in the elections and voting. On the occasion of an exceedingly close electoral contest, however, his vote was challenged on the question of sex, and the subject being referred to a board of physicians, they decided from the presence of a monthly menstrual epoch, that the individual was a female.

Dr. A. L. Mason reported a

CASE OF POISONING BY ILLUMINATING GAS,[1]

and in concluding referred to a similar case reported by Dr. Draper in the last volume of City Hospital Reports.

Dr. Draper remarked that Dr. Mason's case forms an interesting example of this accident. The occurrence of gas poisoning is usually the result of misadventure from leaving a gas-cock open by accident, or from blowing out the flame without turning the cock. Suicide by this means is rare, but Dr. Draper has had occasion to investigate two such cases during the past year. The first was that of a young man who retired to his room, and after twelve hours was found dead in bed. The chamber was tightly closed, the bed was drawn into the middle of the room beneath the chandelier, and a rubber tube was found attached to the tip of one of the fixtures, which conducted the gas to the bed near the face of the victim.

The second case was that of an inventor, who also attached a rubber tube to the gas fixture, the other end of which was placed near his mouth, and held in this situation by a towel bound tightly about the head.

Dr. Draper knew of no instances of homicide by this agent, although considering the facility with which it might be used for homicidal purposes, its deadly qualities when inhaled, and the rapidity of its action, it seemed rather remarkable that it had not figured more extensively in criminal records.

As to the cause of death, Dr. Draper agreed with Dr. Mason that carbonic oxide was probably the chief toxic agent; but it is quite possible that the hydrocarbons present in coal gas exercise a modifying influence both upon the symptoms and upon the post-mortem appearances. Some cases, of which Dr. Draper gave an illustration from his own observations, presented the characteristically altered condition of the blood, the bright color and the extreme fluidity, which indicate the profound effect produced by carbonic oxide upon the hæmatin and blood serum; while in other cases of death by coal gas these distinguishing features were absent, and the blood was dark and contained clots. In the case reported, sufficient time had probably passed between the exposure and the death to permit the blood to become restored in part to its normal state.

The subject of coal-gas poisoning has a sanitary as well as a medico-legal side. Not a little of the ill health of cities might be traced to the usual methods of illumination in houses; not only to the effects upon the atmosphere of the combustion of gas, but to the slow escape of the gas into the air of houses through leaking joints in the pipes, and through defective fixtures, to say nothing of the danger to life by the discharge of gas in detonating proportions.

The light of the future, the electric light, which is not dependent on pipes for its distribution, which does not heat the air intolerably, nor use its oxygen, nor poison it with carbonic oxide, is hygienically a welcome innovation.

As an illustration of the effects of acute gas poisoning Dr. Draper recalled a case of incendiary fire, in which all the tips of the gas fixtures had been removed, and the gas everywhere turned on. In a remote part of the building the dead body of a man was found in which the blood was entirely fluid, and of a beautiful carmine color, which properties it preserved unchanged for some days. The blood also responded to chemical tests for carbonic oxide.

Dr. Mason stated that the color of the blood in the case he reported was normal, and not that usually observed in poisoning from carbonic oxide. In the case alluded to in the City Hospital Reports the blood was nearly black, and contained some ill-favored clots.

In reply to a question from Dr. Shattuck Dr. Draper stated that no changes were observed in the kidneys in these cases.

[1] See page 196 of this number of the Journal.

DR. SHATTUCK remarked that this accident was rare in Boston, the one reported by Dr. Mason be being the first in a long time. In New York, on the contrary, poisoning by gas is of comparatively frequent occurrence, cases of this kind being frequently received at the Chambers Street Hospital.

DR. DRAPER reported a case of

CROUPOUS INFLAMMATION OF THE PHARYNX, LARYNX, AND TRACHEA, WITH OCCLUSION OF THE LARGER BRONCHI.

G. B. P., twenty-two years old, married, and a brakeman, entered Boston City Hospital, January 8, 1883. There was a history of cough of four months' duration, but no other pulmonary symptom. Present sickness began five days before entrance with nausea, vomiting, epistaxis, and headache; sore throat; pain in deglutition. Cough abundant, with whitish expectoration. Slight chilliness and anorexia. Some difficulty in breathing for three days, but wheezing respiration and aphonia of two days' duration.

At time of entrance had a croupy cough and difficult breathing. Could speak only in whisper. Pulse was 120; respirations 28; temperature 103° F. Throat examined by Dr. Prince, who found larynx covered with a grayish deposit which involved the true and false cords. Fauces showed redness only. Steam from an atomizer was inhaled every two hours, and a poultice was applied every four hours to the neck.

He was very restless during the night, and did not sleep. He had six dejections that were loose, but without membrane or blood.

In the morning he had a copper and opium pill, and the spray of salicylate of soda, ten grains to the ounce. Sherry, two ounces every six hours. He coughed up several pieces of membrane, some as large as a silver dollar.

In afternoon respirations 28; pulse 148; temperature 102° F. Chest showed good resonance in front, with some sonorous and sibilant râles; some diminished resonance over left back and feeble respiration. Some laryngeal stridor. Nails and face slightly blue.

Tracheotomy was performed by Dr. Thorndike, and patient lived five hours after operation. During this time had he stimulants freely and steam from atomizer. Breathing was fairly quiet, but pulse rapid and weak. Died very quietly without signs of suffocation.

DR. GANNETT, who had made the autopsy in the case, demonstrated the specimen.

The tonsils were nearly doubled in size, reddened, their crypts filled with partially adherent plugs of fibrine. On the posterior wall of the pharynx were numerous similar patches of fibrine; the mucous membrane beneath being reddened and injected.

A continuous fibrinous false membrane covered the epiglottis, larynx, mucous membrane of trachea and bronchi down to the smallest divisions which could be followed out with fine scissors.

The glottis opening was only large enough to admit a crow-quill.

In the trachea and bronchi down to the fourth division the fibrinous false membrane formed hollow cylinders, below this point solid plugs.

The lungs were œdematous, but contained no excess of blood.

The spleen presented the appearances characteristic of acute hyperplasia of that organ.

There was not sufficient evidence of cloudy swelling of the other organs.

Dr. Gannett further expressed the opinion that as far as the appearances of the air passages alone were concerned one should designate the affection anatomically as a croupous inflammation, but considering the evidences of a septic condition elsewhere in the body, the rapidly fatal course, together with the fact that anatomical evidence of death by suffocation was wanting, would lead one to think of diphtheria, and certainly as far as the Board of Health regulations were concerned it would be better to take the precautions observed in cases of diphtheria.

DR. MASON asked whether benefit was derived from tracheotomy in adults with diphtheria.

DR. DRAPER replied that in the majority of cases no benefit was obtained from this operation.

DR. GANNETT stated that in the light thrown upon the present case by the autopsy it was evident that no medical or surgical measures could have been of the slightest possible service.

In reply to a question, Dr. Gannett stated that the membrane probably developed simultaneously in the throat and air-passages, though this could not be positively determined.

OVARIAN CYSTS.

DR. BLODGETT showed two ovarian cysts which had recently been removed by Dr. John Homans, who had kindly permitted them to be exhibited to the Section. The first was a large sac free from external adhesions, except at the point of attachment by the pedicle. The Fallopian tube was found, and traced fifteen centimetres to its extremity, where were apparently normal fimbriæ. No other remarkable appearances were observed upon the exterior of the sac. The interior of the cyst, however, was seen to contain the ragged remains of former septa which had divided the present large sac into a number of smaller ones, but owing to the attenuation of the walls between these primary cysts, or atrophy, or some other cause, these divisions had been obliterated, thus forming one large cavity. The wall of this cyst was covered on its internal surface by numerous small cysts with thin walls containing a clear limpid fluid.

Dr. Blodgett remarked that the present specimen probably originated from a cystoid process affecting the ovarian or Graafian follicles, by which some or all these structures became the seat of a more or less extensive accumulation of fluid. Coincident with this was a hyperplasia of the connective tissue or stroma of the ovary, the attenuated remains of which formed the boundaries between the separate cysts of which the growth was formerly composed. Many of these primary cyst walls had ruptured, thus forming one large sac. Around the periphery attached to the original but hypertrophied capsule of the ovary were numerous cysts which still remained intact as separate smaller sacs. The appearances of glandular proliferation in the cyst wall described by various writers were not to be seen in this case.

The second cyst presented an entirely different form of ovarian disease. Externally the sac offered no striking appearances. The pedicle was of the average size, and the Fallopian tube could be followed twelve centimetres to its fimbriated extremity. There were no indications of adhesions. The greater portion of the cyst content was fluid, but at the lower part of the sac was felt a firm, hard, nodulated mass of irregular outline and the size of an infant's head. In a re-

mote part of the cyst could be felt another nodule of a similar character, the size of a horse-chestnut. Upon opening the sac the growth was found to consist of a network of pinkish tissue of greatly attenuated character, inclosing multitudes of hard grayish or pearl-colored nodules, which were somewhat raised above the general level of the surrounding tissue, and much resembled the appearance of secondary carcinoma in the liver. In some parts of the growth the nutrition of the mass had been suspended, and necrosis had occurred, with the disintegration of the tissues into a grayish-yellow smeary substance. The nodules upon the cyst wall referred to above were seen to be similar to the mass of the larger growth, and were evidently derived from it by local infection, or transplantation, or metastasis. Microscopic examination showed the pink tissue to be connective tissue, with vascular channels, etc., while the gray nodules were composed of enormous proliferations of epithelium, generally of the squamous variety. In many places the epithelial cells were detached and evidently necrotic. The cellular structure of the secondary growth on the cyst wall was similar to that just described.

The diagnosis was papillary carcinoma of the ovary associated with cystic degeneration, and local infection of the cyst wall. There was no appearance of the cancerous affection having penetrated the cyst wall so as to have extended to other organs, and the interesting question presents itself whether the patient may be supposed to be protected against further danger from carcinoma by the entire removal of the disease while it was still inclosed within the distended capsule of the ovary.

Dr. Gannett said that he must differ from Dr. Blodgett in his supposition that the numerous cysts present represented dilated follicles of the ovary, such tumors not having been observed of large size. He thought they represented an actual new-growth, and were to be classed with the *cystomata* of Waldeyer. The fluid contents, he thought, should not be considered as serum, but rather as the paralbuminous colloid material, investigated many years ago by Eichwald, and which represents the product of the metamorphosis of the cells lining the new-formed cysts.

In regard to the large mass in the wall of the second cyst, Dr. Gannett, while allowing that cancers occasionally developed in the walls of ovarian cysts, yet thought in the present case that it represented not a cancer but rather the papillary form of cystoma.

Dr. Gannett gave also a short sketch of the development of the ovarian cystomata as first shown by Waldeyer and generally accepted by later writers.

NEW YORK ACADEMY OF MEDICINE.

DIET IN THE TREATMENT OF THE GOUTY DYSCRASIA.

At a meeting of the Academy, held February 15th, Dr. William H. Draper read a paper with the above title. He commenced by saying that the subject of food and the problems which arose from its relations to normal and impaired nutrition, and its proper use in the treatment and prevention of disease, were daily attracting more and more attention, and that the practitioner of medicine was now expected to prescribe the diet as well as the drugs for his patients. The recognition of the truth of the old saying, "there's death in the pot," had induced people to inquire of their medical advisers what kind of food and drink they ought to partake of, and judicious feeding constituted an important element in the treatment of every case of disease.

Dr. Draper then made a preliminary statement in regard to some of the theories advanced concerning the nature of gout, which, in its regular, acute form, he said, was a specific arthritis, with an accumulation of uric acid in the blood, and a deposition of urate of soda in the affected tissues. There were, however, a great variety of symptoms which were properly described as gouty, and yet which could not all be satisfactorily explained by any theory yet proposed. Since Garrod's investigations the humoral pathology had been very widely accepted. Having spoken at some length of the chemical theory of digestion, he alluded to the not infrequent concurrence of lithæmia and glycosuria. In both conditions the liver was, no doubt, at fault. Heredity and the mysterious influence of the nervous system, he went on to say, were very important factors in gout, and while it was undoubtedly a disease in which suboxidation occurred, it was impossible to say whether the suboxidation was the essential element or merely an incidental epi-phenomenon. It was a well-known fact that uric acid salts accumulated in the blood in other diseases, and yet did not produce the symptoms of gout. The humoral doctrine was, therefore, still involved in some obscurity.

He next spoke of the neuro-pathology of gout as taught by Cullen, and in connection with it pointed out the frequency with which purely nervous influences determined an attack of gout, and the influence of certain diseases of the nervous system, such as cerebro-spinal meningitis and tabes dorsalis. Such facts, however, did not necessarily militate against the generally accepted humoral pathology.

The treatment of gout, whether based on the chemical theory or on the hypothesis that the affection was a trophe-neurosis, embraced dietetic, hygienic, and medicinal means, and the present paper was devoted to a consideration of the first of these. The successful combating of this dyscrasia involved in every instance a consideration of the quality and quantity of food required. The approximate estimate was necessarily a variable one in different cases, and the age and general condition of the patient, as well as the amount and nature of the work he had to do, were constantly to be borne in mind. In adult life food was required for the repair of waste and for the protection of the individual against heat and cold. It had been proved that all force resided in the food taken, and that there could be no motion which did not result from a preceding one. Daily nutrition had a direct bearing upon the gouty diathesis, and if an excess of food were taken it was impossible that it should all be oxidized. The relations of the quality of food were perhaps less essential, but still of the greatest importance. The amount of the carbonaceous elements required would depend on the physical exertion to be made and the degree of cold to which the individual was to be exposed. It was for this reason that such a large amount of fats was consumed by laborers and by those living in the Arctic regions. A nitrogenous diet, on the other hand, was needed by those who were not much exposed to cold, and who had mental rather than muscular work to do. From time immemorial a special regimen had been

considered necessary for those affected with the gouty diathesis, and it had always been the counsel of the authorities on this subject that gouty patients should partake very sparingly of albuminous foods, and live principally upon farinaceous articles of diet. Dr. Draper's observations, however, went to show that gouty subjects were unable to digest the carbo-hydrates. This kind of food produced acid and flatulent dyspepsia and the very symptoms which usually preceded an explosion of acute gout. In the children of gouty parents over-indulgence in amylaceous and saccharine foods was almost sure to be followed by evil consequences, and great caution in the use of these was one of the surest means of diminishing the liability to acute attacks in those already subject to the disease. The diet, then, in the gouty dyscrasia was to be in the main similar to that required in glycosuria, although it was not necessary that the abstinence from carbo-hydrates should be so strict as that demanded in diabetes. The patient should, therefore, refrain as much as possible from saccharine, starchy, and fatty foods, and especially from all fermented alcoholic beverages. Distilled liquors did not have the same effect, as seemed to be shown by the fact that gout was much more prevalent in England, where beer and stout were universally partaken of, than in Scotland, where whiskey was the drink most indulged in. It was also said that gout was rare in Russia and in Poland, where spirits are principally used. In regard to the effect of wines there was, of course, a difference according to the kind used. Sherry, port, and madeira were the most injurious, but the heavier clarets and burgundies were also to be carefully avoided. The effect of cider was well recognized in the production of gout, and in New England, where it was a common beverage, it often lead to the development of the irregular forms of the disease.

All drinks containing any unfermented sugar were to be excluded, and if the patient insisted on taking wine, he would have to confine himself to the dryest of the dry champagnes, hock, or light claret. But even these could not always be trusted, and the safest alcoholic beverage that could be taken was a very diluted spirit. Indulgence in saccharine food ranked next to that in wine and beer in danger, and it was an important point to observe that this excluded the use of many fruits, such as strawberries, apples, and oranges. Next in importance in this connection came amylaceous articles of diet; but it was not necessary that these should be entirely abstained from, but only that they should be eaten in moderation. They did most mischief in those inclined to obesity and who led sedentary lives. All kinds of salads, tomatoes, and the various succulent vegetables free of starch, could be taken with impunity. In obstinate cases the milk diet was of the greatest utility. The digestion of the carbo-hydrates was always more or less impaired in gouty individuals; but if an active outdoor life were engaged in, it was not necessary to look after the diet so carefully. The gouty man who remained in-doors much of his time, however, would do well not to live upon potatoes and puddings.

DR. HADDEN remarked that the dietetic treatment advocated by Dr. Draper was essentially the same which he had himself adopted for the past five years, and with very gratifying success. The theoretical problems in connection with gout still remained unsettled, and he was more particularly interested in the clinical aspect of the matter. His experience had been to the effect that nitrogenous food, fully allowed, counteracted the gouty dyscrasia in a very remarkable manner, and he had already published a number of cases which seemed to establish this point beyond question. These were principally subacute and chronic cases, and the meat diet, used both day and night, had in every instance at once diminished the quantity of urates.

It was his practice to cut off entirely, as far as possible, all starchy and saccharine foods, just as he did in cases of diabetes mellitus. Not infrequently his old patients wrote him that if they transgressed the rules which he had laid down for them the gouty trouble was almost sure to come back again. All the medicinal means which he had employed had been simply for the relief of some temporary condition complicating the case. Thus, salicylate of soda had sometimes been given for the purpose of counteracting fermentation of food in the stomach. In many cases where gases in the intestines had previously been very troublesome, the patients had no further difficulty of this kind after commencing the nitrogenous diet. As a confirmation of the correctness of the views now advocated he remarked that it had been observed that parrots, pigeons, and other birds fed upon starchy food not infrequently had chalk-stones about their feet, while in carnivorous birds, such as eagles and vultures, this condition was never found. The same difference had also been observed in herbivorous and carnivorous quadrupeds.

DR. MARY PUTNAM JACOBI said that Dr. Pepper had recently called attention to the fact that certain individuals in whom there had never been any deposit of lithates, and who had always previously enjoyed good health, were suddenly seized at the age of thirty, thirty-five, or forty, with hypochondriasis, and that they were entirely cured by a resort to a milk diet alone. This seemed to be unquestionably one of the protean forms in which the gouty dyscrasia manifested itself. That the meat diet diminished the amount of uric acid she had herself incontestibly proven in a great many cases by a quantitative analysis. She was accustomed to restrict her patients to an absolute meat diet and gluten bread, and this plan had always been followed by a marked decrease in the symptoms present. Dr. Draper had not said anything about the difficulty of keeping patients upon such a restricted diet as this, and she thought it was a point of some importance. One patient of hers suffering from obesity and debility became exceedingly prostrated after using it for ten days. She then, however, gave her nux vomica and nitro-muriatic acid, under the idea that the liver was at fault, and after that she had no further trouble. In the course of a year she had lost forty pounds and had regained her strength.

DR. JANEWAY remarked that one fact struck him as rather peculiar, namely, that milk, which while highly nitrogenous, yet contained a large amount of sugar, should be of so much service. It seemed to him that in the treatment the main thing was to avoid acid dyspepsia. In regard to the pathology of gout, if it was taken to be of neurotic origin, the characteristic gouty deposits ought to be found more frequently, he thought, than they were in nervous patients. Again, it was not uncommon to see gout determined by an injury or by some nervous attack; but the real reason why the gout occurred, as it seemed to him, was because some dys-

peptic trouble was thus excited. On the whole, the humoral pathology seemed to be the more satisfactory.

In reply to Dr. Putnam Jacobi, DR. DRAPER stated that while difficulties sometimes occurred in getting patients to adhere to the proper kind of food, he had never found it necessary to restrict the subjects of gout to so exclusively a nitrogenous diet as she had done. In a few cases with obstinate lithæmia he prescribed a milk diet, but as a rule it was only necessary to restrict the amount of sugar taken, and see that the patient ate only a moderate quantity of wheaten bread and other starchy foods. Patients were apt to be rebellious, and it was sometimes necessary to allow them certain indulgences. He generally advised plenty of green, succulent vegetables, as these did not seem to interfere with the success of the treatment, and they added greatly to the comfort of the patient. As to the sugar in milk, this was certainly one objection to it, but he was of the opinion that whenever a milk diet was prescribed the patient should at the same time be directed to take more or less alkali. When soda, for instance, was used with the milk he had found that it was almost invariably well borne.

DR. FLINT thought that in order to settle the question of what treatment was appropriate in the gouty dyscrasia it was best to depend upon clinical observation rather than any merely theoretical views. What the profession needed on this subject was a sufficient collection of facts in regard to the results of different kinds of diet. As to dyscrasia, there was, perhaps, no disease in which a dyscrasia played so important a part as in gout.

DR. DRAPER said he quite agreed with Dr. Flint as to the desirability of gathering a mass of clinical facts on the subject. In regard to the pathology of the affection, his aim had been to show clearly that the diet which had been most successful could not be explained or justified by any theory that had yet been suggested, and he did not believe that any one could offer a satisfactory explanation why an animal diet was best in the majority of cases. He could only say that his experience had demonstrated to him that nitrogenous food offered the patient the best protection against all the various manifestations of the disease.

DR. HADDEN said that in his experience a milk diet was not well borne in subacute and chronic gout, and he believed that this was on account of the sugar which the milk contained. In some cases he used instead of gluten bread wheat bread which had been very thoroughly toasted.

Remarks were also made by DRS. KINNICUTT, BARKER, and PIFFARD.

— A contemporary suggests that with the progress of electrical science a new weapon will be put into the hands of assassins and murderers, and that death can be caused so as to leave no pathological or chemical traces sufficient for detecting its ætiology. Certainly it would not be strange if some ingenious and educated criminal should make use of such an instrument, especially now that the "humanitarians" are advocating its employment for the destruction of superannuated and superfluous animals. The suggestion of electricity as a substitute for hanging as a means of execution of criminals is also being renewed.

Recent Literature.

Report of the Pennsylvania Hospital for the Insane for the Year 1882. By THOMAS S. KIRKBRIDE, M. D., Physician-in-Chief and Superintendent.

This report, which is the forty-second of the institution, and, what is more remarkable, the forty-second of Dr. Kirkbride's, is as usual of much interest. There is the same spirit of contentment, good nature, and confidence in the future which has always characterized the Pennsylvania Hospital Reports, and made them very pleasant reading.

At the end of the last year there were 398 patients in the institution, since which time, to January 1, 1883, 193 have been admitted, and 183 have been discharged, leaving 408 as the present number. Sixty-six recovered, and twenty-three died. Four of the deaths were from general paralysis.

The number of patients received into the hospital since its opening has been 8673.

This is the fourteenth year during which there has been some sort of amusement furnished the patients every evening during nine months of the year. Modeling in clay and painting in oil are branches of occupation recently and successfully introduced. We are especially glad to see that the cultivation of flowers by some of the ladies, in gardens under their immediate control, has been practically tried and been found satisfactory. It is an undoubted fact that manual labor out-of-doors, in some form, is the best occupation for the insane, and we hope the day is not far distant when we shall see large numbers of the gentlemen and ladies in private asylums hard at work in the flower and vegetable garden, priding themselves on the small number of weeds their gardens contain.

Taking the insane hospitals at Harrisburg, Dixmont, Danville, Warren, and Norristown, there are accommodations, or soon will be, for over 3,000 insane patients without crowding, and private asylums will accommodate about 700 more. These figures show creditable progress, Dr. Kirkbride says; if there are, however, over 8000 insane persons in the State of Pennsylvania, it will be some years before all the insane are provided for.

Laws should be made forbidding the admission of the insane into almshouses, or their retention therein, and for the exclusion of insane criminals from ordinary insane hospitals.

The early treatment of insanity is of the utmost importance; and the number of lives sacrificed by allowing insane persons to be at liberty is very large. As many as twenty-seven years ago Dr. Kirkbride found that the number of persons whose lives were sacrificed or jeopardized by the insane who were allowed to be at large in the United States was equal to those lost by all railroad accidents. The number may not be so large now.

Mental diseases should be made a study of in medical schools, and some knowledge of the functions of the brain, and of the courses of life likely to lead to their disturbance, should be imparted to the pupils in ordinary schools.

Insane hospitals, and treatment in them, should not be such bugbears as they have been, and a closer understanding of them will probably remove some of the mistaken ideas now held concerning them.

The effect of hereditary influence as a cause of in-

sanity has been often greatly exaggerated. Out of 5381 cases of primary attacks of insanity, for instance, hereditary influence could be traced in only 434. This gives us less than one in twelve, and is, we are certain, below the actual relative proportion.

When we take the extreme difficulty of getting at the causes of insanity, and especially the still greater difficulty of obtaining even the most meagre family history of insanity, we see how very liable statistical tables concerning hereditary influence will be to err. Then, too, human nature has been, and is now, for that matter, so weak, that many persons are positively ashamed to "own up" to insanity in their sisters, their cousins, or their aunts, or any one else in the family. It is also a fact, that in the immense number of the pauper insane there are but few instances where the friends are sufficiently intelligent to give any information at all about heredity. It is a great and misty conundrum, which is given up or evaded by a negative reply. W. C.

The Management of Chronic Inebriates and Insane Drunkards. By ALBERT N. BLODGETT, M. D. Boston: 1882. Read at the annual meeting of the American Social Science Association, September 6, 1882.

Dr. Blodgett discusses in an able and interesting manner a subject of the greatest importance. In this country we hear a good deal about drunkenness, but chiefly from temperance lecturers or would-be reformers, who usually overstep the bounds of truth and look at the question almost entirely from the moral or sentimental side. This point of view is an important one, but it offers little that is practical or scientific in the direction of remedial agencies. When, therefore, a scientific paper, like that of Dr. Blodgett, is presented to us, we read it with great pleasure.

Dr. Blodgett thinks that there has been a great increase in abnormal development of the nervous system among American and other people during recent years. "There is an increased excitability, an abnormal activity of all the cerebral and nervous functions." The causes of the increased nervous tension are numerous. It is impossible to enumerate them all, but among them may be mentioned, the modern science of politics, of the kind in which personal ambition usurps principle; the abolition of principle; the mania for speculation; the insatiable desire for wealth; the rapid dissemination of intelligence. Another potent factor is the changes in the private and domestic life of the people. Large cities are over-crowded, and in them much of the quiet restraint and peaceful influence of home life is lost. The young of both sexes are too soon thrown into the vortex of excitement, and often have insufficient self-control to withstand the temptations by which they are surrounded.

Human nature cannot long bear the strain thus put upon it. There is a limit to human energy, and it is necessary either to relax the strain or resort to the use of some form of artificial stimulus. Unfortunately the latter course is the one often followed. By frequent indulgence the habit thus formed of using stimulants becomes fixed, and finally the person who first began the habit for the purpose of temporarily replacing lost vitality by alcoholic stimulants becomes a chronic inebriate.

The second class, that of insane drunkards, is composed of persons who inherit constitutional defects, or are congenitally weak-minded. These persons do not usually become addicted to the use of alcoholic stimulants from an original necessity for them. Their nervous systems are so constituted that they at once feel the effect of powerful stimulants, and as it were come under their influence. Gradually the intellect becomes impaired, and the power of self-control is lost, so that some form of restraint becomes necessary.

Unfortunately no institutions exist which are exactly suited to the needs of either class. The private asylums, which are often conducted on certain dogmatic, religious, or hygienic principles, where patients are received as voluntary boarders, are not at all what is needed, and lunatic asylums or prisons are also lacking in proper facilities for treatment.

A severe case of alcoholic insanity may often do very well in a lunatic asylum; but the so-called insane drunkard creates an endless amount of trouble among insane patients. As the immediate effects of the alcohol begin to leave him he begins to show a restless, irritable, fault-finding, unreasonable disposition, and often he incites mischief among his fellow patients. Dr. Blodgett speaks of the demoralizing effects the surroundings have on the inebriate, and we have no doubt there are such effects; but we are inclined to think the drunkard does more harm than is done to him.

Dr. Blodgett speaks of the uncertain length of time of treatment now allowed for insane drunkards. We can bear witness that it is now impossible to find any place where a dipsomaniac can be held with any degree of certainty for a fraction of the time his case demands.

In Germany Dr. Blodgett found that fine roads had been built, and other work done out-of-doors by persons undergoing short sentences, often for drunkenness. If similar work could be done by chronic drinkers, under proper management for long periods of time, cures might in some cases follow. W. C.

— The Greek dramatist who originated the maxim "knowledge comes by suffering," might have said *per contra*, "suffering comes by knowledge." This remark is suggested by an editorial article of a contemporary, who has been made miserable by Koch's discoveries and theories. The writer very properly inveighs against straw in the street-cars; that it is productive of much filth and nastiness none will deny. But that the straw furnishes a culture nidus for the development of tuberculous germs expectorated into it by afflicted passengers is an apprehension which would keep none but a "bacterianist" awake o' nights. The opening of the mind's eye to all the different germs floating in our surroundings is certainly not conducive to a habit of rest and quietness.

— An exchange contains the following anecdote of Abernethy: Being actively engaged in inserting a cervical seton in "a noble patient," who had requested that this should be done, his patient exclaimed, "Sir, you give me excessive torture; will your seton do good." "No, sir," said the doctor. "Then why do you insert it?" screamed the patient. "Because," said the doctor, "you told me to do so, and I will get five pounds for my work."

Medical and Surgical Journal.

THURSDAY, MARCH 1, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the under signed, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 Park Street, Boston, Mass.

PASTEUR'S REPLY TO KOCH.

The *Revue Scientifique* (January 20, 1883,) contains Pasteur's reply to Koch's criticism of his methods and results in regard to the micro-organisms of disease and the value of attenuated virus for inoculative purposes. Pasteur's reply is preceded by his critic's remarks translated into French. A summary of Koch's attack was published in the Journal of January 18th.

It is to be regretted that abstract questions of scientific truth or error cannot be divorced from the personalities of discoverers and wrangling over priority, that "such anger should possess celestial minds." The expanse of the unknown is broad enough for all voyagers to pursue their way without collision. Such discussions seem to be the inevitable accompaniment of every discovery, and we should, perhaps, rather regard them in the light of the shifting wind, necessary to clear away fog banks, and make plain all the details of new and hitherto but fitfully illumined surroundings, or, to change the metaphor, they may be regarded as the reagent needed to clear up a cloudy liquid.

We must confess, however, that any advantages to be derived from the discussion by abstract science would have been quite as attainable had it been started by Koch on a somewhat different key, excellent though his brochure was as a mere polemical effort. The form which the dispute has taken is tinged with a certain acrimony, borrowed in part, perhaps, from the difference in nationalities, and in part from the difference in ages.

All will recognize that Pasteur has done some remarkable work — we may even, in the German fashion, call it epoch-making work — in the province of scientific medicine, and he duly invites attention to it in his reply to Koch. If the latter accomplishes as much more in twenty years from the date of his first publication in 1876 he may well congratulate himself. The science and the profession which they serve, and the public whom they benefit, will know how to honor both investigators. To Pasteur we must, probably, accord the full credit of solving the riddle of the nature of the ferment in what were formerly known as zymotic diseases, and of teaching the possibility and developing a method — if not the best method — of the attenuation and inoculation of the virus. Koch himself already acknowledges that the secret of splenic fever has been forced, and he now confesses that Pasteur must be credited with working out the attenuation of the active principle of disease ferments. In these respects at least Pasteur is a genuine "path-breaker," and has enabled Koch to make his own brilliant discovery of the bacillus tuberculosis.

The action of micro-organisms as ferments or tissue destroyers, and the attenuation of their virulence, are to be regarded as far-reaching principles acquired for science. There have been and will be mistakes in regard to the significance of this or that particular microbion, and the manner in which attenuation of a virus is brought about — whether directly by oxygen and temperature, or indirectly by these, and directly by increased activity in the organisms themselves — may have been misinterpreted; generalizations have been at times too hasty. These considerations should not be allowed to obscure the great principles involved.

Let Koch and his fellow-workers in this field continue, by absolutely pure cultures, to enlarge the number of infectious diseases having a demonstrable connection with a given microbion, by a more exact interpretation of the processes taking place to develop better methods of attenuation of virus, by greater experience to arrive at surer and safer methods of inoculation. There is work here for the time and energies and ingenuity of all interested in these questions, and there are still absolutely unknown regions in the domain of science for the bolder spirits who must be always in the vanguard, and are impatient of a neighbor however distant. There is no excuse here for the elbowing and crowding attendant upon long occupation.

DEFECTIVE VISION AMONG RAILROAD EMPLOYEES. ATTEMPT TO PREVENT EXAMINATIONS.

A bill has been introduced into the Legislature to stop any test of the form or color sense of employees except by the "railroad signals." Now it has been repeatedly and most clearly shown that not even the most skilled experts can detect color-blindness or decide on a man's eyesight by any use of the railroad signals, even where all question of collusion was eliminated. On the other hand a very few minutes with the most practical test used by the government will settle whether a man is safe or not.

A similar attempt to break down the law was tried last year and failed through the efforts of the gentlemen who have had experience in testing in this country. If the evidence then presented could have been put in print before the community and the Legislature, this second attempt would not have been heard of, because if ignorance is the cause, then a thorough knowledge of the subject would have been disseminated. There is, however, strong reason to believe that the plea of ignorance will not hold, and that the seemingly plausible argument of allowing experts or others to test *only* by railroad signals arises from the desire and hope to break down the law which practically prevents the color-blind or purblind from holding positions when their defects endanger our lives and property on railroads.

Another order passed the House which requires the railroad committee to consider if any change is requisite in the present law, with full power to send for papers and persons, employ a stenographer, and report in print.

There can now be no excuse for not having a full and complete report of all the evidence and arguments for the community to read and be instructed by. The railroad committee have the power to find out just what the corporations have done, whether they have obeyed the present law or not, and what methods they have employed to test, who they employed to examine, and what standard of requirement these persons exacted; in other words, whether the present law protects the community *and* the employee.

We have repeatedly stated the need of *legal* standards of requirement of visual power and color sense, and the absolute necessity of thoroughly competent experts to decide whether the individual employee came up to such standard, not set by the examiner.

THE CARTWRIGHT LECTURES FOR 1883.

DR. W. T. BELFIELD, lecturer on pathology in the Rush Medical College, Chicago, delivered the annual Cartwright lectures of the Alumni Association of the College of Physicians and Surgeons at Association Hall, New York, on the evenings of February 18th, 20th, 24th, and 27th. His subject was The Relations of Fungi to Disease, and having fully explained the two systems of bacteria culture adopted by Pasteur and Koch, he argued that the former was so liable to error as to be practically worthless as a basis for scientific investigation, while the latter, which was now coming into general use, had the advantage of being both simple and accurate. He showed that the study of bacteria and similar organisms was one of great difficulty on account of the morphological similarity of many species possessing widely different forms, and maintained that the only way of determining their true character was by means of isolated propagation and the inoculation of healthy tissue with the organisms thus obtained. Pasteur's method of accomplishing this was defective, owing to the impossibility of securing during the transfer of bacteria from flask to flask complete immunity from the accession from the air and instruments employed of other varieties of bacteria, which, by their more rapid breeding, might entirely crowd out the species under investigation. In Koch's method of propagation on gelatine, under microscopic observation, this source of error was avoided, and the pedigree of the bacteria ultimately selected for inoculation tests was, he believed, guaranteed with certainty. In opposition to the charges of Prof. H. D. Schmidt, of New Orleans, and other pathologists, that Koch's *bacilli tuberculosis* were either strings of fibrine or fat crystals, Dr. Belfield stated that they had been proved to stand tests which were fatal to both of these hypotheses. In the first place they propagated in sterilized breeding grounds, and in the second they absorbed aniline by endosmosis. In addition, after repeated breedings, the remote descendants of these bacilli had been found to produce tuberculosis in previously healthy organisms. Bacteria had been observed to give rise to anthrax by several competent investigators, and after the researches of Koch in regard to phthisis it seemed altogether probable that they would be found to be concerned in the causation of leprosy, erysipelas, diphtheria, septicæmia, cholera, yellow fever, and other diseases of infectious type. In the opinion of Dr. Belfield the experiments of Koch were conclusive, and he thought that the only possible objection that could be made to them and their results was that he might have erred in observation or in application. As, however, during a long course of pathological inquiry the German investigator had never as yet been found to commit an error, he did not consider such objections of much importance; but still, in order to finally set the question at rest, he thought it would be well that all Koch's experiments should be carefully repeated by a considerable number of competent mycologists.

THE NEW YORK CODE.

NOTWITHSTANDING all the touching and beautiful talk in the New York County and State Medical Societies in regard to the matter of "humanity" and the "elevation of the standing of the profession," it would at first sight seem rather a significant fact that the new code agitation was entirely inaugurated by specialists, and that every man who has taken at all an active part in securing its adoption and preventing its repeal is a specialist. It is probably, however, only a curious coincidence that the specialists are the ones who must necessarily derive the largest amount of pecuniary benefit from consulting with all "legally qualified practitioners of medicine." Among legally qualified practitioners our new code friends in New York will, no doubt, be much pleased to learn that they may now have the opportunity of meeting in consultation the noble and good Dr. Buchanan, lately of Philadelphia, who, we are informed on excellent authority, is now a registered physician in their city, and who, having graduated from Moyamensing, as well as a medical college, must have had special opportunities of study and experience, which the profession and public ought not to be slow in availing themselves of.

There is one point, involving to some extent the matter of consistency, which the ordinary Philistine medical mind is not quite capable of satisfactorily comprehending. How is it that the very gentlemen who are the most energetic and persistent supporters of the new code are also those who are most clamorous for the higher education of the profession, and are the leaders in establishing innumerable post-graduate courses to this end in every department of medicine and surgery, when by this same new code any Tom, Dick, or Harry who can buy, steal, or study six weeks for a diploma is placed on the same level as a graduate of Harvard or the University of Pennsylvania, who has spent a couple of years or more in the hospitals after receiving his degree?

MEDICAL NOTES.

— We have received a bound volume of one of our most valued exchanges, the *Sanitary Engineer*. Such publications, treating the problems presented by the massing of large populations in narrow limits, are of great value to preventive medicine, especially so when conducted with the scientific ability which characterizes our contemporary.

— An ingenious German has conceived and carried out a plan for the manufacture of gas from human fæces. "These are put in a retort, where they are not only dried, but decomposed by heat, the chief products being a light yielding gas, carbonic acid, tar, oil, and ammonia. As in ordinary gas works, the tar and oil are separated, the gases washed by being passed through water, the carbonic acid fixed, and the light yielding gas purified for use. There remain in the retorts the ash-constituents with a portion of carbon, which the inventor designates coke." The authority for this description, *Der Techniker*, informs its readers also that a Breslau Hotel has already been successfully lighted by means of this novel and presumably economical gas.

— The Health Officer of a city not famed for the general ignorance of its population considered it his duty to ask an individual who certified that a certain patient of his had died of malaria, what he meant by that term. The answer was as follows: —

"Malaria was the cause, poisoning the blood, producing dormant, parlytic, Costive, Chronic conditions, and inert Tumors; which terminated in Acute inflamation of the Liver, from taking a sudden cold.

"——— ——— Magnetic Physician."

— Dr. Traill Green, the President of the American Academy of Medicine, in the annual address delivered at Philadelphia in October, strongly sets forth the advantage, we might almost say the necessity, of a good preliminary education for those who are to study medicine, and gives abundant quotations from the most eminent men in the profession in favor of raising the standard of requirements for the degree of M. D. The speaker says: —

"In 1876, the year of our organization, we believe the Medical School of Harvard was the only school in this country which required a preliminary examination of intending medical students; now there are thirteen colleges which require the diploma of a literary institution or a preliminary examination, and three schools require a preliminary examination; one of the thirteen is not a regular school. This is progress, great progress, in six years, and the value now attached to a degree from a medical college requiring a preliminary examination, or a degree in the liberal arts, shows that the course pursued in these institutions is approved. It is quite common now to see Harv. written after the Harvard M. D. This will be followed, and the colleges which demand this examination will have public sentiment to sustain them, as well as that of students who are ambitious of good standing in our profession."

— One of our most egregious charlatans has added a second string to his bow in the shape of a subscription to a valuable mining stock which in the exuberance of his philanthropy he has decided no longer to keep to himself but to share with the dear public. But even such a double-headed swindle as this hides its diminished vertices before the operations of a quack in Missouri who fleeced a patient, then deliberately castrated him, and finally seduced his wife, which, to put it mildly, was adding insult to injury.

— An unmarried woman in France administered a teaspoonful of creosote to her infant with a fatal result. The post-mortem appearances were those of an escharotic poison, and the odor of creosote was marked. The woman, however, thought she was administering laudanum, and though she knew the latter drug to be a poison, the charge against her fell through, and she was acquitted. (*Annales de Hygiène*, February, 1882.)

— A regatta at Evesham, England, was followed by sixty-eight cases of typhoid fever among persons who attended it. An investigation developed the fact that nearly every one had drank lemonade at a refreshment stand, the proprietor of which had mixed the beverage with water from a disused well that was closed because it was known to be foul. Whether or not this well had been contaminated by a specific typhoid infection does not seem to have been established.

NEW YORK.

— The coroner's jury in the case of Michael Kelleher, who was recently killed by a fellow-patient in the alcoholic wards of Bellevue Hospital, have rendered the following verdict: "We find that Michael Kelleher came to his death by injuries inflicted by George E. Mahan; that in view of the evidence before us we believe that due care was not exercised by the officer in charge of the alcoholic ward, and that in our opinion the system of management is very defective; that the wards should at all times be in charge of a responsible employee, and that the orderlies are highly censurable for leaving the wards without putting the patients in charge of a responsible person. Further, we consider that the furniture of the rooms should be of such a character and so secured as to prevent the possibility of their use as weapons of offense by the patients." This jury comprised among its members three ex-mayors of the city, a physician, Dr. William Balser, and Mr. Townsend Cox, ex-commissioner of charities and correction. Among those subpœnaed to act on it, but who were excused from attendance, were General Grant, Jay Gould, and William H. Vanderbilt. During the inquest Coroner Marble explained that it was not because of any desire for notoriety that he had summoned so many prominent citizens to serve, but because he believed that the good name and welfare of the city institutions demanded in this case a more thorough investigation than usual.

— The treasurer's report of the Hospital Saturday and Sunday collection of 1882, which has just been made public, shows a falling off in the amount designated for special hospitals of no less than $6379.63, while the collection for the general fund is but $3893.10 less than that of last year. The total amount collected in 1882, which was at first reported to be only about $20,000, was in reality $32,262.72, against

$42,535.45 in 1881, and $44,371.97 in 1880. The causes of the decline in the amount are supposed to be the general depression of business as compared with the last two years, which manifests itself both in the trade and church collections, and the pressure of other benevolent causes at the time the collection was made. The report complains that comparatively few of the churches made any offerings. Thus out of fifty Presbyterian churches only eleven contributed this year; out of thirty-eight Baptist churches only one contributed; out of twenty Reformed (Dutch) churches only six contributed; out of fifty-five Methodist churches only four contributed; out of twenty-five Hebrew synagogues only eight contributed; and out of fifty-seven Roman Catholic churches, which furnish a very considerable proportion of the charity patients of the various hospitals of the Association, none have contributed to their support. The report then goes on to say that "a new and efficient committee has been appointed by the Association to promote the formation of trade auxiliary associations, and we are convinced that when it is once fairly and generally understood that for every dollar contributed through these auxiliaries the hospitals of the Association agree to furnish one day's care to any suffering tradesman of their own craft, auxiliaries will be formed as a matter of self-interest and self-protection in every trade, and, as in England, the workmen themselves will gladly unite with their employers in "penny-a-week" contributions towards providing for themselves or their families in times of accident or sickness."

— General Egbert Viele, the distinguished engineer, having recently been appointed one of the Commissioners of Parks, at the last meeting of the Park Board made a report in which he referred at length to the present unsatisfactory and unhealthy condition of Central Park, and made suggestions for its improvement. The park, he said, especially from the time that it had been officially but erroneously said to have been completed, had undergone a gradual but sure decadence until its complete renovation had become an imperative duty. The first step in its renovation, he said, was to restore it to a proper sanitary condition. To this end a careful sanitary inspection should be made as soon as the weather would permit of all the ponds, lakes, and collections of water, the sources of supply and the outlets, for the purpose of determining what measures should be adopted to prevent them from being detrimental to the public health. It was asserted by those having official knowledge of the fact that many miles of underground drains were obstructive to the flow of water, serving the sole purpose of retaining moisture in the soil. Another element of insalubrity was the over-planting found in the park, especially in the matter of shrubbery. These dense masses of low undergrowth served to impede the free circulation of air, to exclude the sun from the earth, and to keep the soil in a state of moisture that promoted vegetable decay, and gave rise to noxious vapors. It was, consequently, advised that a general but judicious pruning and transplanting should be done during the coming season.

— The annual address, delivered by the President, Dr. John J. Mitchell, of Newburgh, before the Homœopathic State Medical Society, which met in Albany February 13th, was on the Future of Homœopathy, and was based on the recent action of the regular State Society in regard to the code of ethics. The modest position of our homœopathic *confrères* may be gathered from the following selections from it: "As to success in our practice, we had presented statistics until we were tired, all demonstrating to the unprejudiced student that in the great mass of curable diseases our mortality was scarcely one half that of our professional brethren of the 'regular' school. . . . Now I submit that such a record as this alone ought in honesty to send every 'regular' practitioner to his study, and there by earnest work for a year or two he may acquire the ability to achieve a like success. . . . In regard to the resolution offered by the 'regulars' last year, we would state that we did not, directly or indirectly, ask any such action. The resolution having been adopted we hailed it as a good omen. We knew that we could do them good in the department of the practice of medicine to which for half a century we had specially devoted ourselves. Any response on our part was not necessary, for they were merely coming to the position that we had occupied for a score of years. . . . We shall be obliged to exist in our organized capacity until a chair of the theory and practice of homœopathy shall exist in all the medical colleges in our land. The time of which I dream will surely arrive."

— At a meeting of the County Medical Society, held February 26th, Dr. Charles Heitzman read a paper on The Intimate Nature of Tuberculosis: its Transmissibility and its Parasitic Origin; the points treated of being as follows: recent corroborations of Heitzman's discoveries by S. Stricker; inflammation in general; inflammatory nature of tuberculosis; constitutional origin of tuberculosis; Koch's bacilli.

— Dr. F. C. Valentine recently performed transfusion of blood in a case of partial asphyxia by illuminating gas. Six ounces of blood were injected, and the patient recovered; but as the number of respirations had begun to increase before the transfusion was resorted to, it seems probable that recovery would have taken place without the transfusion in consequence of the use of artificial respiration and the other ordinary means adopted.

— On the 14th of February Louise Stannard, a girl twelve years of age, died in the Mount Sinai Hospital, where she had been under treatment since the 26th of December last, for a bullet wound in the head. She was accidentally shot by a playmate with a toy pistol, and the bullet, which passed directly through the centre of her forehead, remained embedded in the brain up to the time of her death. The girl rallied from the first shock, and, although not permitted to leave the bed, recovered the use of all her faculties, and seemed in a fair way of recovery; when, on the fifty-first day after the receipt of the injury, she was suddenly seized with coma and in about ten minutes was dead.

— By the will of the late ex-Governor Edwin D.

Morgan, who died February 14th, $795,000 was left to charities. Of this sum the Woman's Hospital receives $25,000; the Home for Incurables, $5000; the House of Rest for Consumptives, $5000; the Society for the Relief of Sick Poor, $5000; the Society for the Relief of the Ruptured and Crippled, $20,000; the Presbyterian Hospital, $50,000; and the Manhattan Eye and Ear Hospital, $50,000. At the time of his death Governor Morgan was president of the board of managers of several of these institutions, and for a number of years had devoted a great deal of personal attention, as well as given large amounts, to them.

CHICAGO.

— The fortieth Commencement of Rush College occurred on the 20th inst. The number of the graduates was 179, and there were no honorary or *ad eundem* degrees. The Faculty appeared at the Commencement in the scholars' robes of the University of London for the first time. Prof. Moses Gunn gave the address. This had for its subject the ethics of the profession. He discussed the American Code, and considered the recent propositions to modify its rigor. That part of the Code which undertakes to regulate the conduct of the public toward the profession was foolish and inoperative. If it was proper for a regular physician to sit in a State Board of Health with irregulars it was inconsistent to object to the modification of the Code proposed by New York as to consultations. The Faculty gave a banquet in the evening to the alumni of the college at the Grand Pacific Hotel. Over 350 guests were present.

Miscellany.

THE TREATMENT OF DELIRIUM TREMENS.

A WRITER in the *Practitioner* (January, 1883), deprecates the old "homœopathic" treatment of alcoholism, that is, the administration of stimulants, even in reduced quantities, and also insists that in the severe cases opium, digitalis, and capsicum are powerless to effect a cure. It is true, he says, that in the first stage of alcoholism the appetite being fairly good, and the blood corpuscles in fairly normal proportions, chloral is quite sufficient to calm the excited circulation and produce sleep; but in the second stage, when the appetite is bad, the blood corpuscles deficient in quantity and shriveled, and the brain anæmic and starved, it is useless to expect relief from sedatives unless the brain is at the same time supplied with the nourishment it requires. Death, no doubt, in delirium tremens arises from want of sleep, but then it must be remembered that the want of sleep is caused by want of nourishment. The most important part of the treatment, then, is to improve the quality of the blood as quickly as possible by throwing into the system frequent supplies of light, nourishing, and easily digestible food, and the best way of accomplishing this end is by cutting off all stimulants and ordering liquid essence of beef and half a pint of milk to be taken alternately every two hours. As regards medicine, twenty-five grains of chloral with hirty minims of compound tincture of cardamoms in an ounce of water taken every four hours, after the beef tea, will be found most useful. Very little effect, though, is produced by the first dose of the chloral, inasmuch as the brain is without the nourishment it requires, but after the second dose the food begins to tell — some sleep, generally speaking, results, and this goes on increasing in proportion as the support is maintained. If nourishment is withheld sleep disappears, and the old delirium returns.

By this treatment the patient is generally free from all delusions in about thirty-six hours, but good strong liquid food must still be taken for some days, though not quite so frequently. When there have been from ten to twelve hours more or less continuous sleep, then it is advisable to give up the chloral, and give thirty minims of the compound tincture of gentian with five minims of the tincture of nux vomica three times a day for about three days. This restores the tone of the nervous system and stomach, and creates an appetite. A little tincture of euonymin may next be substituted for the nux vomica, and some Carlsbad salt may be given in the morning when required. By this treatment the duration of the delirium and the after-effects of the alcohol are very much lessened.

ELECTRIC STORAGE WORKS AND LEAD POISONING.

THE following, from the *Lancet* (January 27th), upon the above subject, may have a practical interest for physicians in our larger cities where various forms of electric accumulators are being experimented with.

We have not as yet heard of any cases of lead poisoning in connection with electric storage as occurring in this city or in New York.

"It seems that another manufacture is added to the list of those in which the health of the operatives engaged is likely to be injuriously affected by the poisonous effects that the materials employed have upon those who are constantly brought in contact with them. For some time past several cases of plumbism have occurred at the East-end of London among the laborers engaged in some large 'electric storage' works. Inquiry has shown that the lead in these cases is probably introduced into the system by means of the substance used to cover the plates of the storage batteries. We do not know the exact nature of this paste, but it is made on the premises, and part of the process consists of mixing a powder containing lead with strong sulphuric acid. During the procedure fumes are given off. In one of the cases brought under our observation the toxic effect due to lead had been rapidly induced, and the patient exhibited, in addition to the usual blue line on the gums, the rarer phenomenon of extensive deposit on the buccal mucous membrane. But the cases of plumbism have not been limited to those who prepare the paste, since several instances have occurred among those handling it in applying it to the plates. It is probable that the majority of the cases have arisen from the men not being fully acquainted with the dangerous nature of the material they were dealing with. It is to be hoped, now that attention has been drawn to the matter, necessary precautions will be taken by the management of the companies engaged in the manufacture of these batteries to prevent any more cases occurring among their work-people. The use of masks in rooms where the paste is made and the fumes given off, and the wearing of stout leather gloves, often renewed, by those who have to apply the paste to the

plates, would, we think, check the evil. An inspector of factories ought, however, at once to visit and report upon these establishments, and suggest any further precautions that might occur to him after inquiring into the nature of the various operations carried on."

EXPERIMENTS UPON RABBITS WITH CONVALLARIA MAJALIS.

THE following are given as the results of his experiments upon rabbits with convallaria majalis, by Dr. Isaac Ott, in a paper published in the *Archives of Medicine* for February: —

"These experiments demonstrate: —

"(1.) That convallaria increases the arterial tension greatly at the same time as the heart begins to beat more frequently; that the heart begins to fall before the tension.

"(2.) The decrease of cardiac frequency is not due to cardio-inhibitory excitation, but to an action on the heart itself, probably its muscular structure.

"(3.) The rise of arterial tension is mainly due to stimulation of other vaso-motor apparatus than the main monarchical vaso-motor centre.

"(4.) The drug causes clonic spasms.

"If we compare the action of this drug with digitalis, it is found that the slowing of each is due to different causes: with digitalis it is due to a cardio-inhibitory excitation; with convallaria some other part of the heart is the agent. Digitalis, as a rule, does not primarily accelerate the heart; convallaria does. After section of the spinal cord digitalis is powerless to increase arterial tension, whilst convallaria does. If now we compare the action of this drug with other cardiac agents, as aconite, urechites suberecta, or astragalus mollissimus, it is found that it does not belong to this group. As aconite, urechites, and astragalus resemble each other in their action, yet many important differences exist, so does convallaria differ from digitalis in several important particulars. The great rise of arterial tension would indicate its value in dropsies, reasoning upon Ludwig's theory of renal secretion. It is a drug which must not be pushed to any great extent, if I am to judge from a rather extensive experience with cardiac agents upon the hearts of the lower animals."

TREPHINING FOR INTRA-CRANIAL ABSCESS.

IN the *Dublin Medical Journal* for January, 1883, is reported a case in which the operation of trephining was performed on account of an abscess resulting from a fall in the hunting field. The patient was unconscious for two hours after the accident. At the end of a fortnight he was removed to Dublin, suffering much from pain over the upper part of the occipital bone on the right side, and also much gastric irritability and general debility. Any motion, such as driving, intensified the pain, and caused nausea. On examination a shallow depression, the size of a florin, was found, bound by a well-defined margin, at the situation where he complained of the pain. The diagnosis of fracture, with the subsequent formation of an abscess within the cranium at the seat of the lesion, was made. An exploratory incision was made down to the bone, and a small purulent collection was opened into. Subsequently the operation of trephining was undertaken, and on exploring the bone a small circular opening through the skull, about two lines in diameter, was discovered. Through this opening, situated on the upper part of the occipital bone, some purulent matter oozed. A circular piece of bone was then removed with the trephine to provide free exit for the pus. An abscess cavity, from which almost half an ounce of pus welled up, was opened into. The inner surface of the piece of bone removed was deeply eroded. The cavity of the abscess was washed out with a weak solution of carbolic acid. Subsequently the patient experienced an attack of erysipelas of the head and neck, from which, however, he recovered, and nothing further occurred to interrupt the process of complete recovery.

A REMARKABLE CASE OF GLASS SWALLOWING.

THE *Australasian Medical Gazette* (December, 1882) contains the report of a case in which a German military officer in Berlin swallowed, in November, 1875, a piece of glass which had been broken from the neck of a bottle, and had fallen into the glass from which the individual was drinking beer. The fragment was of triangular shape, the hypothenuse one inch, the base three eighths inch, and the thickness one eighth inch. At first there was only a sharp pain felt in the region of the arytenoid cartilage. In about an hour a prolonged fit of coughing came on, which was frequently repeated. Dyspnœa, dysphagia, hæmorrhage, and acute pain marked the next few weeks, and attempts to remove the body were unsuccessful. Then he began to have intermittent febrile attacks, with vomiting at first of dark-colored coagulated blood, and later of blood and very fetid pus. The latter caused relief (for the first time) to the pain, and fall of temperature. Swallowing also became easier. In March, 1876, a swelling was noted in the region of the right fossa infraclavicularis, and the patient could feel the gradual descent of the pain toward the clavicle, and later along the sternum. While he was in a hospital for a possible operation the pain fixed itself just below the xiphoid cartilage. Vomiting became increasingly frequent, with cough and chills. Blood was vomited. Then an acute pyrexia developed, with vomiting of pus, which again relieved the pain, and enabled the patient for the first time in weeks to straighten himself up from the nearly right angle at which his pain had constrained him to keep his body. No operation was undertaken. In January, 1877, another exacerbation occurred which was very nearly fatal. He was then obliged to be fed with an œsophageal tube. Hypodermic injections of chloroform at the seat of pain were given with such frequency as to cause a localized spot of inflammation. This became gangrenous and sloughed. Through this opening a probe detected the foreign body, and an enlargement of the wound permitted its extraction. Speedy and complete recovery followed.

— From a secular contemporary, concerning the faith cure: "Have you ever tried the faith cure?" asked a long-haired, sallow-faced stranger, addressing a gentleman who sat behind him in a street-car. "I have," was the answer. "Do you believe in it?" "I do." "May I ask, then, of what you were cured?" "Certainly. I was cured of my faith."

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 17, 1883.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from				
				The Principal "Zymotic" Diseases.	Lung Diseases.	Diphtheria and Croup.	Scarlet Fever.	Small-Pox.

Deaths reported 2969: under five years of age 1017: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 568, lung diseases 491, consumption 470, diphtheria and croup 183, scarlet fever 90, small-pox 80, typhoid fever 51, diarrhœal diseases 31, malarial fevers 29, cerebro-spinal meningitis 28, puerperal fever 21, whooping-cough 20, measles 19, erysipelas 16. From *typhoid fever*, Pittsburg 12, Philadelphia 11, District of Columbia and Providence four each, Brooklyn, Boston, and St. Louis three each, New York, Chicago, Baltimore, and New Orleans two each, Buffalo, Salem, and Somerville one each. From *diarrhœal diseases*, New York 10, St. Louis five, Pittsburg three, Brooklyn, Boston, and Cincinnati two each, Chicago, Baltimore, New Orleans, Milwaukee, Providence, Cambridge, and Holyoke one each. From *malarial fevers*, New York 12, New Orleans seven, Brooklyn five, Chicago, St. Louis, Baltimore, New Haven, and Springfield one each. From *cerebro-spinal meningitis*, New York eight, New Orleans five, St. Louis three, Chicago and Buffalo two each, Cincinnati, Pittsburg, Providence, Nashville, Lowell, Fall River, Lawrence, and Woburn one each. From *puerperal fever*, Chicago five, St. Louis and Baltimore three each, Boston and Peabody two each, New York, Brooklyn, Cincinnati, Milwaukee, New Haven, and Lowell one each. From *whooping-cough*, Chicago and Cincinnati three each, Brooklyn, St. Louis, Pittsburg, and New Haven two each, New York, Philadelphia, New Orleans, Milwaukee, Lynn, and New Bedford one each. From *measles*, New York and Philadelphia seven each, Cincinnati three, Chicago and New Haven one each. From *erysipelas*, Chicago six, New York, Cincinnati, and Providence two each, St. Louis, Milwaukee, Fall River, and Taunton one each.

One hundred and thirty-eight cases of small-pox were reported in Baltimore, Pittsburg four; diphtheria 20, scarlet fever 17, and typhoid fever three, in Boston; scarlet fever 12 and diphtheria seven in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of 1,309,495 (population of the State 1,783,086), the total death-rate for the week was 16.09 against 21.25 and 20.78, for the previous two weeks.

In the 28 towns of England and Wales, with an estimated population of 8,620,975, for the week ending February 3d, the death-rate was 23.7. Deaths reported 3910: acute diseases of the respiratory organs (London) 382, whooping-cough 106, scarlet fever 103, fever 77, measles 46, diarrhœa 40, diphtheria 31, small-pox (London five, Liverpool one) six. The death-rates ranged from 17.9 in Portsmouth to 35.3 in Sunderland; Brighton 18.8; London 21.7; Norwich 22.1; Newcastle-on-Tyne 23.7; Birmingham 24.5; Leeds 25.5; Liverpool 30.9; Blackburn 34.6. In Edinburgh 19.2; Glasgow 30; Dublin 34.

For the week ending January 20th, in 170 German cities and towns, with an estimated population of 8,516,807, the death-rate was 26.1. Deaths reported 4267: under five years of age 1850; consumption 668, lung diseases 487, diphtheria and croup 203, scarlet fever 75, typhoid fever 54, whooping-cough 49, measles and rötheln 48, puerperal fever 17, small-pox (Königsberg, Elbing, Breslau, Neisse, and Darmstadt one each) five. The death-rates ranged from 14 in Karlsruhe to 39 in Chemnitz; Königsberg 26.2; Breslau 30; Munich 26.2; Dresden 23.8; Berlin 25; Leipzig 25.3; Hamburg 26.6; Cologne 23.7; Frankfort 21.2; Strasburg 26.3.

For the week ending January 27th, in the Swiss towns, population 494,390, there were 42 deaths from lung diseases, consumption 39, diphtheria and croup 13, diarrhœal diseases 12, typhoid fever six, scarlet fever one, puerperal fever one. The death-rates were, at Geneva 15.4; Zurich 20; Basle 23.8; Berne 28.2.

For the week ending February 3d, in the Swiss towns, population 494,390, there were 33 deaths from consumption, lung diseases 26, diphtheria and croup 13, diarrhœal diseases nine, typhoid fever nine, puerperal fever three, small-pox one. The death-rates were, at Geneva 19.5; Zurich 10; Basle 24.6; Berne 22.6.

The meteorological record for the week ending February 17th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 9, 1883, TO FEBRUARY 23, 1883.

DELOFFRE, AUGUSTUS A., captain and assistant surgeon. Relieved from further duty in this Department. S. O. 28, Department of the Missouri, February 5, 1883.

TAYLOR, B. D., captain and assistant surgeon. Granted leave of absence for one month, on surgeon's certificate of disability. Paragraph 2, S. O. 13, Department of Texas, February 1, 1883.

NEWTON, R. C., first lieutenant and assistant surgeon, is relieved from duty at Fort Cummings, N. M., and will proceed to Fort Sill, I. T., and report to the commanding officer for duty. S. O. 28, Department of the Missouri, February 5, 1883.

CLEARY, PETER J. A., captain and assistant surgeon. Granted leave of absence for four months on account of sickness, to take effect January 3, 1883, in extension of his authorized absence on certificates of disability. Paragraph 6, S. O. No. 40, A. G. O., February 16, 1883.

HEIZMANN, CHARLES L., captain and assistant surgeon. To be relieved from duty in the Department of the Columbia. S. O. 12, Department of the Columbia February 8, 1883.

A. B. HAGGETT, paymaster of the Middlesex Mills at Lowell, has been appointed a member of the Massachusetts Board of Health, Lunacy, and Charity in place of G. P. Carter, Esq., whose term had expired.

NOMINATIONS by the Governor to the Board of Trustees of the Massachusetts General Hospital, as lately announced, were withdrawn, and the members of last year were reappointed with one exception.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at No. 19 Boylston Place, on Monday, March 5, 1883, at eight o'clock P. M. Reader, Dr. G. H. M. Rowe. Subject, The Training of Nurses. Drs. J. H. Whittemore and W. L. Richardson will open the discussion. Dr. M. H. Richardson will report An Unfavorable Case of Empyema, with Demonstration of the Thorax.

C. M. JONES, *Secretary.*

THE SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY will meet on Wednesday, March 7th, at 7.30 P. M. Congenital Dislocation of the Hip, with Exhibition of Patients, Dr. Abner Post. Contractions of the Knee-Joint; Reports of Cases and Exhibition of Apparatus, Dr. E. H. Bradford, Dr. F. S. Watson, Dr. H. L. Burrell. H. C. HAVEN, *Secretary.*

BOOKS AND PAMPHLETS RECEIVED. — The Treatment of Acute Rheumatism. An Analysis of the Results obtained under Different Systems of Treatment in St. George's Hospital during the Years 1877 and 1878. By Isambard Owen, M. D. London: J. & A. Churchill.

Experimental Pharmacology. A Hand-Book of Methods for Studying the Physiological Actions of Drugs. By L. Hermann, Professor of Physiology in the University of Zürich. Translated with the Author's permission, with Notes and Additions, by Robert Meade Smith, M. D. Philadelphia: Henry C. Lea's Son & Co. 1883.

Report of the Pennsylvania Hospital for the Insane for the Year 1882. By Thomas S. Kirkbride, M. D., LL. D., Physician-in-Chief and Superintendent. Philadelphia. 1883.

A Manual of Histology. Edited and prepared by Thomas E. Satterthwaite, M. D., of New York, in association with Drs. Thomas Dwight, J. Collins Warren, etc., etc. Second Edition, enlarged and revised, containing two hundred and two Illustrations, with an Appendix. New York: William Wood & Co. 1882.

Consultation Chart of the Eye Symptoms and Eye Complications of General Diseases. Arranged after Foerster and others by Henry G. Cornwell, M. D. Columbus, Ohio.

Third Biennial Report. Kansas State Charitable Institutions. 1881–1882.

The Sanitary Engineer. Vol. VI. June to November, 1882. New York.

The Best Method of Treating Operation Wounds. By Henry O. Marcy, A. M., M. D., of Boston. (Reprint.)

The Placental Development in Mammals. A Unity of Anatomical and Physiological Modality in all Vertebrates. By Henry O. Marcy, M. D., of Boston. (Reprint.)

A Winter Climate for Invalids. The Gulf Coast of Florida. By R. J. Levis, M. D. (Reprint.)

Studies from the Pathological Laboratory of the University of Pennsylvania. No. X. The Pathogenesis of Secondary Tumors. By Henry Wile, A. B., M. D. Rochester, N. Y. (Reprint.)

Studies from the Pathological Laboratory of the University of Pennsylvania. No. XI. The Bacillus Tuberculosis, and some Anatomical Points which suggest the Refutation of its Ætiological Relation with Tuberculosis. First Communication. By H. F. Formad, B. M., M. D. (Reprint.)

The Prevention of Insanity. By Nathan Allen, M. D., of Lowell.

Scrofula and its Gland Diseases. An Introduction to the General Pathology of Scrofula, with an Account of its Histology, Diagnosis, and Treatment of its Glandular Affections. By Frederick Treves, F. R. C. S. Eng. Philadelphia: H. C. Lea's Son & Co. 1883. Price 10 cents.

The Compend of Anatomy for Use in the Dissecting Room and in preparing for Examinations. By John B. Roberts, A. M., M. D. Third Edition. Philadelphia: C. C. Roberts & Co. 1882.

The Physiology of Alcoholics. An Address by William B. Carpenter, M. D., LL. D., F. R. S. New York: National Temperance Society and Publication House. 1883.

Annual Report of the President and Treasurer of Harvard College. 1881–1882.

Bromide of Ethyl. The most Perfect Anæsthetic for Short Surgical Operations. By Julian J. Chisholm, M. D.

Naso-Antral Catarrh and its Treatment. By W. H. Daly, M. D. Pittsfield, Mass. (Reprint.)

The Law of Human Increase. By Nathan Allen, M. D. (Reprint.)

Original Articles.

OCULAR SYMPTOMS AS LOCALIZING SYMPTOMS.[1]

BY S. G. WEBBER, M. D.

PARALYSIS or irregular action of the muscles of the eye has been long noticed as associated with cerebral lesions — indeed it would scarcely be possible to overlook such a prominent symptom; but the reference of definite ocular symptoms to definite lesions was not possible till there was a more accurate study of both than prevailed only a few years since. Andral, in 1834, mentions the "deviation of the eye in some one direction," and speaks of strabismus as then most generally observed.

Conjugate deviation of the eyes, and especially when associated with rotation of the head, could not fail to attract notice when seen; as, however, it is generally a fugitive symptom, lasting only a few hours or days, it would often not be seen, and at other times would not be thought important. In 1858 Prevost called attention to this group of symptoms — in cases of lesion of one of the hemispheres, with deviation towards the side where the lesion is situated — in cases of lesion of the cerebral isthmus, towards the opposite side.

This symptom is of comparatively little value as diagnostic of lesion of the hemispheres; it simply reveals that fact. It may occur with superficial lesions, or with lesions of the cerebral substance, becoming more frequent as the lesion is situated nearer the corpus striatum and the fibres radiating from the cerebral peduncle.

When conjugate deviation of the eyes occurs as the result of a lesion of the pons the symptom is more persistent; it is towards the hemiplegic side, away from the lesion in case of paralysis; away from the hemiplegic side towards the lesion in case of spasms; at least this is the classical statement.

So many important nuclei and commissures are grouped together around the pons Varolii that any symptom connected with lesions in that vicinity is an interesting subject to study.

The anatomy of the medulla, pons, and crura, gives valuable assistance to an understanding of the symptoms associated with disease of those parts.

The seventh nerve enters the pons at one side, passes inwards and backwards nearly to the floor of the fourth ventricle to the eminentia teres; the course is not straight but curvilinear. At the eminentia teres the fibres turn downwards, pass just below the floor of the ventricle for a short distance, then turn again, run outwards, forwards, and slightly upwards, to their nucleus, the inferior facial nucleus. Some of the fibres of the facial probably run into a nucleus found at the bend of the nerve as it turns downwards, the superior nucleus of the facial, the nucleus of the sixth nerve.

The sixth nerve or the abducens enters the medulla just at its junction with the pons, and passes backwards through the pons to the above nucleus.

The third nerve enters the tegmentum of the crus cerebri near the upper (anterior) border of the pons. As soon as the nerve enters the crus the fibres separate, some pass with only a gentle curve to the nucleus at the edge of the gray substance surrounding the aqueduct of Sylvius, others spread out in a fan shape, but after passing or crossing the anterior cerebellar peduncle the fibres converge again and enter the same nucleus.

There is a band of longitudinal fibres running near the floor of the fourth ventricle, called the *posterior longitudinal bundle of the tegmentum*, by Huguenin.[2] This bundle of fibres is shown on cross sections by Wernicke,[3] who says [4] that it looks as though a large part of this bundle arose from the nucleus of the third nerve.

Duval has made longitudinal sections so as to show the course of the fibres composing this bundle, and has found that they take their origin below from the nucleus of the sixth nerve (Figs. 1, 2), cross the upper branch of the knee of the seventh nerve, then approaching each other they reach the nucleus of the fourth nerve; before quite reaching that nucleus, however, small bundles separate from the internal

FIG. 1.

FIG. 2.

FIG. 1. Longitudinal section, parallel with floor of fourth ventricle; showing the thin bundle of fibres, running from the nucleus of the sixth nerve, in the bend of the seventh, which decussates and is lost at the nucleus of the third nerve. *After Duval.*

FIG. 2. Transverse section, showing the decussation of the same bundles of fibres, and illustrating how they pass into the third nerve without running into its nucleus. *After Duval*

border of each, decussate and pass forwards (downwards) to join the third nerve. Many more of the fibres of these bundles unite with the fourth nerve. The fibres which pass from the longitudinal bundles to the third nerves form the anterior and internal fasciculi of those nerves.

Huguenin [5] says, in regard to the union of the abducens with the nucleus of the oculo-motor and trochlear, that he has seen, on horizontal section, fibres which, decussating, seem to unite the upper portion of the abducens nucleus with the nucleus of the oculo-motor nerve.

By the above commissural arrangement is explained the harmonious action of the eyes in lateral vision. It is not necessary here to consider all the advantages of such a relation of nuclei. There are times, however, when it is desirable that the eyes should not act thus together in lateral vision. When it is wished to look at near objects, as in reading, the internal recti must act with each other independently of the external recti. For this purpose these muscles are also supplied with nerve fibres from the proper nucleus of the third nerve without the intervention of the abducens nucleus.

Hunnius [6] gives a diagram of the innervation of the

sixth nerve from the brain and its possible connection with the third.

From the cerebral cortex *G*, *G'*, arises the motor tract, *m*, *m'*, which conveys the impulse for turning the eyes sideways to the abducens centre, *a*, *a'*; these decussate somewhere in their course, probably in the anterior part of the pons. From the abducens nucleus *a*, *a'*, arises the abducens nerve passing to the external rectus *Re*, *Re'*; also from the same nuclei bundles of nerve fibres, which decussate, pass to the opposite third nerves *o*, *o'*, which innervates the internal rectus *Ri*, *Ri'*. Hunnius represents also a centre *c* for converging action of the two eyes, which is also united with the cerebral cortex. *B* represents the pons.

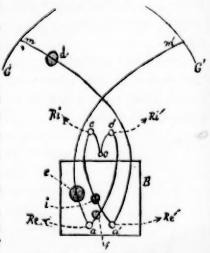

FIG. 3. *After Hunnius.*

In the figure the shaded circles, *d*, *e*, *i*, *f*, are given by Hunnius to represent lesions so located as to give rise to different combinations of deviation, conjugate or otherwise.

A lesion situated as at *d* before decussation of the fibres, innervating the external rectus nucleus, will give rise to the conjugate deviation depending upon lesion of the hemisphere. A lesion after decussation as at *e* or affecting the nucleus of the sixth will produce symptoms the opposite of the former. There should be, then, in paralyzing lesions conjugate deviation towards the affected limbs, away from the lesion, or if the lesion is irritative there should be spasm or contraction of the opposite limbs with spasmodic deviation away from the limbs, towards the lesion, usually without rotation of the head. A consideration of the diagram will suggest several possible combinations of lesions with symptoms which rarely or never occur. It is possible to have the commissural fibres running from the sixth to the third nucleus affected before decussation, as at *f*, the sixth nucleus escaping; this might give rise to divergent strabismus. It is scarcely possible to have these fibres affected after decussation, and not find the other motor ocular fibres also affected, for the decussation occurs close to the nucleus of the third nerve.

I saw the first case through the courtesy of Dr. Edes, who was at that time in attendance. It is an instance of conjugate deviation of the eyes from paralysis due to lesion of the nucleus of the sixth nerve. There were other symptoms localizing the lesion in the pons, as myosis; the fact that the fifth and seventh nerves were affected on the same side with the limbs, but the sixth on the opposite side, alternate paralysis of the sixth; also the extreme anæsthesia would aid to a diagnosis of locality.

CASE I. HÆMORRHAGE INTO LEFT SIDE OF PONS, EXTENDING INTO CRUS CEREBRI AND BURSTING INTO FOURTH VENTRICLE; RIGHT HEMIPLEGIA AND RIGHT FACIAL PARALYSIS; CONJUGATE DEVIATION TO RIGHT.

A. B. There is a little uncertainty as to the manner in which this patient was first attacked. The most probable history is that he had been accustomed to the use of liquor; once before he had been similarly affected; had headache, though not very severe, preceding the present attack, and suffered just before from vertigo. The day on which he was taken sick he returned home from work at noon, felt badly in his head, and was dizzy; went out to be in the fresh air and to get a cup of tea, and fell. It is not certain that he was unconscious. He was not entirely paralyzed on either side. He was brought to the hospital about five o'clock in the afternoon. There was partial paralysis of the left eyelid; both pupils were rather small and responsive to light, the right a little larger than the left. The mouth was drawn to the left; the tongue was protruded to the right. There was complete paralysis of the right hand and arm, partial paralysis of the right leg. On testing for ankle clonus a tremor was excited in the whole right leg, continuing as long as the toes were held; there was no such action on the left side. Tendon reflex was very slight, if any, on either side; cremaster reflex was present on the left, not on the right; there was no marked abdominal or epigastric reflex on either side. There was no lead line. On being spoken to he apparently heard perfectly well, but was unable to make himself understood. He was able to swallow only liquids in small quantities slowly. On being shown written questions he thought he could see if he had his glasses, but was unable to do so when they were given him. Temperature on entrance was 98.4° F., pulse 64. Urine was normal in color, neutral, specific gravity 1014, albumen, a trace; sediment, a little pus, a few hyaline and granular casts.

Three days after entrance he was lying on his back, head in the median line, eyes nearly closed, mouth slightly drawn to the left. He was unable to speak, but protruded his tongue when told to do so, and responded in a limited degree to other requests. Sight was not entirely lost, for he followed the finger with his eyes. The left hand and arm and left leg were moved spontaneously, but the limbs of the right side were motionless. Any motion of the face was confined to the left side, the right remaining motionless. The eyelids were both nearly closed, both could be raised, but not fully. The right pupil was of medium size, and responded readily to light; the left pupil was very small, and responded only slightly to light. The left eye did not turn outwards, but moved with tolerable freedom in all other directions; the right eye could not turn inwards, but moved outwards readily, and upwards and downwards with less freedom. The tongue was protruded strongly to the right. Swallowing was very difficult.

Sensation was seemingly entirely wanting on the right side of the face and in the right limbs; a knife stuck into the right hand or leg gave rise to no sign of pain, but a much gentler prick on the left side immediately excited opposition.

Cutaneous reflexes were absent or very slight on the right, but well marked on the left.

There was, then, paralysis of the third nerve on the right in the fibres going to the internal rectus, weakness on both sides in those fibres going to the eyelids, and irritation of the pupillary fibres on the left. The fifth nerve was paralyzed on the right, not on the left. The sixth nerve was paralyzed on the left, was intact on the right. The seventh nerve was paralyzed on the right as to its lower branches. The hypoglossal was paralyzed on the right. The other nerves of the medulla oblongata could not be satisfactorily examined

on account of the patient's condition. The difficulty in swallowing and talking did not necessarily arise from paralysis of those nerves, though it might be so. The limbs were totally paralyzed on the right both as to motion and sensation. Reflex action was seriously impaired or lost on the right.

The temperature was rather high during the first few days; it then was nearly or quite normal, once a degree below normal, and again ran up to 105° F. at the time of his death.

A lesion of the hemispheres is rarely, if ever, accompanied with such serious disturbance of sensation as was found in this case. This feature would limit the locality of the lesion to the crus cerebri or pons or medulla, that is, it must be below the anterior extremity of the crus.

Both the seventh and fifth nerves were paralyzed on the same side as the limbs, therefore the lesion must be above the origin of those nerves, that is, above the middle of the pons.

There was conjugate deviation of the eyes towards the right, partial ptosis on both sides, great contraction with very slight mobility of the left pupil. Conjugate deviation of the eyes towards the sound side in hemiplegia of cerebral origin is not very rare when the hemispheres are affected, and in that case the head is usually turned in the same direction; as Prevost said, the patient seems to be trying to look at the lesion in his brain.

Conjugate deviation of the eyes towards the hemiplegic side has been found heretofore only in cases of lesion of the pons. Nothnagel says that persistent unilateral myosis is found in disease of the pons, and on the same side with the lesion. When the sensation of the limbs is seriously impaired in lesions of the pons it is the external portion which is affected rather than the median.

From these data a diagnosis was made locating the lesion in the anterior and outer portion of the pons.

As to the nature of the lesion, the mode of onset excluded all those which, commencing almost imperceptibly, gradually extend and increase in severity, such as interstitial changes and tumors, excepting the rare cases in which tumors are latent, till a sudden apoplectic attack shows their presence. This is so rarely the case that practically it may be excluded unless further consideration should oblige a return to it.

Hæmorrhage and embolism habitually give rise to apoplectiform attacks. Three symptoms or groups of symptoms will enable us to exclude the latter, — there were prodromic symptoms, — headache, vertigo for some days preceding the attack, and these sensations rather more severe just before it occurred; the loss of power was not most marked immediately after the shock, but the dullness and paralysis steadily increased from the first. There was no record of his temperature until some hours after the attack, but from the time it was first taken there was a rise, interrupted by a slight fall towards midnight. This rise was more steady and higher than would probably be found in embolism. Considering the locality of the lesion the chances are in favor of a hæmorrhage; if the basilar artery were plugged it was probable that death would have resulted sooner, that the symptoms would have been less markedly unilateral; also an embolism of that artery is very rare, and an embolism of its branches is much more rare. For these reasons a diagnosis of hæmorrhage was made, occurring primarily in the anterior and external portion of the pons, but as the symptoms had been steadily increasing in gravity it was thought that the blood had torn up the tissue of the pons to a certain extent around the original focus.

Autopsy made by Dr. Gannett. Only the head was examined. The pia mater was of the usual thickness. Both vertebral arteries about three centimetres before uniting were dilated to about twice their usual calibre; their walls at these points were thickened and of an opaque yellow color. The lateral ventricles each contained about five cubic centimetres of clear fluid; the ependyma was everywhere smooth and shiny. The brain substance in general was quite firm, puncta cruenta well marked. The gray cortex of its usual color and thickness. Nothing unusual was observed on section of the basal ganglia except a small hæmorrhage into the inner portion of the outer capsule. The anterior half of the left side of the pons was represented by a soft, semi-fluid, red mass; in its posterior half only the outer portion of the pons presented this appearance. The outer portion of the anterior part of the left side of the medulla presented the same appearance. The hæmorrhage extended also into the left crus cerebri and left crus cerebelli, and had burst through the floor into the fourth ventricle just anterior to the acoustic striæ on the left side. This hæmorrhage was confined entirely to the left side; it did not quite reach the median raphe of the pons, and, judging from the condition of the tissues, it probably began in the outer and anterior portion of the pons.

CASE II. TUMOR OF LEFT CEREBELLUM AND LEFT SIDE OF PONS; DEGENERATION OF LEFT SIXTH NUCLEUS; CONJUGATE DEVIATION TO RIGHT; PARESIS AND SPASM OF LEFT LIMBS.

Mr. R. B., aged sixty, was seen with Dr. Chase, of Dedham, June 9, 1882. He had always worked hard, and had occasionally had headaches till about eight years ago; from that time he had worked harder than ever. Three years ago he had trouble from overwork. The commencement of his illness was referred by the patient to three months before he was seen, but before that his wife noticed that he was less steady than formerly, that buttons requiring the use of the left hand were buttoned with greater difficulty. The patient first noticed that his legs were weak, and that he could not walk well; this difficulty in walking increased, but he was not laid up. He also found trouble in using his mind; having been very skillful in figures he was not able to perform the problems he desired to work out. His left side gave him the most trouble. He had been confined to bed only two or three weeks. He had had severe headaches, during which his head was drawn down towards the right shoulder, and his face was turned to the right; there had been dizziness, but no nausea. The left arm had been affected with tremor, and at times the whole body also.

When seen he was in bed, head turned to the right, and the eyes to the right; he could move both eyes to the left, but it was with a jerking motion, and not so far as normal. The left eye, following the finger with the right eye closed, moved towards the left very badly; the right eye, with the left closed, moved better than the left. The pupils were equal, reacted to light normally. The left lids moved less readily, and shut less tightly than the right. The left side of the face was slightly paralyzed; the tongue was protruded straight; the left arm was weak and not useful; when raised

above his head a tremor commenced when it was about on a level with the shoulder, and this increased as it was raised higher, and became of wider excursion till it resembled choreic motions. In ordinary positions there was scarcely if any tremor; the arm could not be used so readily as the right. Both legs moved fairly well without tremor. Cutaneous reflex was normal; tendon reflex could not be tried satisfactorily as he could be raised only for a very short time for ophthalmoscopic examination; the change of position caused very great vertigo, and could be maintained only a minute or so. Sensation was diminished on the left. The fundus of the eyes was normal. There had been no loss of consciousness. The symptoms came on gradually.

Autopsy. — Dr. Cutler made the autopsy and has furnished the following notes: There was atheroma of the arteries at the base, most marked on the right of the basilar, and there it seemed to encroach upon the calibre of that artery and to interfere with some of the smaller vessels arising therefrom. On both sides at the end of the carotid there was atheroma, most on the right, and extending on that side into the middle cerebral. The right posterior cerebral was nearly occluded, but a fine stream of water could be forced through it. There were many smaller patches of atheroma dotted over the vessels of the circle of Willis.

The two hemispheres were adherent along the longitudinal fissure; this was probably inflammatory. The pia mater was moderately full of blood; no thickening except along the longitudinal fissure. On section the puncta cruenta were well marked. There was nothing abnormal in the hemispheres.

A little anterior to the middle, the pons was slightly softened; a little lower the tissue became striated, alternate yellow and gray, was somewhat translucent, resembling in color œdematous connective tissue; this mass of abnormal tissue was irregularly oval, hard to the touch, and extended with a sinuous course into the left cerebellar lobe; the left corpus dentatum was obscured by it. In the pons the new growth extended nearly to the medulla, being confined to the left side.

One sixth nerve was atrophied.

The other organs were essentially healthy.

The specimen, as I received it from Dr. Cutler, had been some time in alcohol, and I was not willing to wait long enough to see whether it would harden well in Müller's fluid. The sections for microscopic study were not so continuous and satisfactory as could be wished; but the most important parts showed well. The tumor had no clearly defined edge towards the pons, yet it could be seen that the deep nucleus of the seventh nerve was not destroyed, but just external to that nucleus the seventh nerve passed through the tumor and must have suffered in its conducting power in that part of its tract; at least that would explain the facial paralysis on the left. Anterior to the nucleus of the seventh nerve the tumor apparently approached nearer to the median line.

A large proportion of the nucleus of the left sixth nerve was healthy. In one section through the middle of the nucleus there were many degenerated nerve cells, and the number of cells was evidently less than that on the right of the same section.

The diagnosis at the time the patient was examined was tumor in the basal ganglia or cortex on the right or in the pons on the left, possibly implicating the cerebellum. The latter was considered the more probable.

Besides the conjugate deviation of the eyes the peculiar irregular motion on raising the left arm is worthy of notice. It is also of interest that there was such extensive change of the cerebellum and of part of the pons, yet no retinitis was present. The vertigo might have been expected, as it is a common symptom in cerebellar tumor. The fact that the head was drawn towards the right shoulder during the severe attacks of headache is also of interest.

The symptoms in this case are peculiar, but seemingly are easily explained. The tumor, as shown on section, did not affect the great motor tract of the pons, the pyramidal fibres which run near the anterior border of the pons, hence we have no paralysis of the right side. The facial nerve runs through the tumor, and that nerve was partially paralyzed. The tumor was situated in the left middle cerebellar crus, and extended into the pons. The specimen had been long in alcohol when I received it, and it was cut so that exactly how much of the pons was affected I could not say with certainty. Brown-Séquard has shown that lesions in this vicinity may give rise to partial paralysis on the same side with the lesion; hence the weakness of the left limbs. The spasm developed in the left arm by raising it cannot be readily explained; it was very much like the phenomenon known as post-hemiplegic chorea. The conjugate deviation was away from the side of the lesion. But in this case the regular order of symptoms was broken, for there was weakness and spasm of the left side, that on which was the tumor, and the deviation was towards the opposite side. In this regard the case is anomalous.

(To be continued.)

THE ACTION OF QUININE UPON THE EAR.[1]

BY J. ORNE GREEN, M. D.

THE specific action of quinine upon the ear in producing tinnitus aurium is so well known that it is apt to be considered of no consequence, and its effects upon that most important organ, whether for good or evil, are in too many cases, it seems to me, neglected, while the attention of the physician is occupied in watching the action of the drug on the general disease for which it is administered. Many cases which have come under my observation have so thoroughly convinced me of the great injury often done by the drug, and these observations agree so well with the known pathological tendencies of the ear, and with the more recent physiological experiments on the action of quinine, that I desire to call attention to them. Works on materia medica, it is true, universally speak of the tinnitus aurium, but none with which I am acquainted seem to consider that the aural symptoms may be a contra-indication for the exhibit of the medicine in certain cases, and none give any cautions so far as the ears are concerned in regard to its use. Even so late an authority as Ringer, in his admirable Handbook of Therapeutics, contents himself by saying merely that it occasionally produces deafness, which usually passes off, but in rare cases remains for life.

Recent observations on the action of quinine show that its effect is to produce a pathological condition of the ear, which, if excessive or long continued, en-

[1] Read at a meeting of the Medical Improvement Society, February 26, 1883.

dangers the integrity of that organ; a pathological condition very similar to that produced in certain aural diseases, which are well known to seriously impair the functions of the ear, and that not by any occult and unknown principle, but by well-known laws of histological changes, which produce interferences with the established rules of physiology and physics.

It was formerly claimed that the action of quinine was the production of contraction of the blood-vessels, and consequently anæmia of the ear; this was early denied by Von Graefe, as contrary to his clinical experience, and any one who has watched the effects of quinine when given to a patient suffering from acute inflammation of the ear can satisfy himself in a very short time that the drug, if pushed to its specific effect, most decidedly increases the existing inflammation. I have myself watched many such cases, and consider the effect as undeniable. In 1874 Hammond [1] asserted that he thought the effects of the drug upon the ear were due to congestion, and in 1874 Roosa [2] also asserted the same thing, and gave the results of experiments performed by him upon three medical men, the result of the experiments being that the administration of the drug was followed in each case by a decided congestion of the blood-vessels, which run along the manubrium in the membrana tympani. In two of the cases there was very marked tinnitus aurium accompanying this congestion, while in the other case, that in which the congestion was the least, there was no tinnitus. The blood-vessels which were seen to be congested in these cases are known to be intimately connected with the vascular system of the middle ear; in fact, they form such an important part of this tympanic system that in the earlier stages of acute inflammation of the tympanic mucous membrane congestion of the vessels along the manubrium is one of the earliest diagnostic appearances. The blood-vessels of the tympanum are also in direct connection with the circulation within the labyrinth as has been proven by Politzer, by means of injections, and as is occasionally shown clinically by the marked tympanic congestion which accompanies inflammations of the labyrinth in cases of extension of disease from the brain to that cavity. From the very close relations of the vascular systems of these three parts, the membrana tympani, the tympanum, and the labyrinth, and from the appearance of congestion as the direct result of the administration of ten and fifteen grain doses of quinine in the carefully-conducted experiments of Roosa, we have strong evidence that the effect of the drug upon the ear is congestive rather than anæmic; but inasmuch as the amount of the congestion visible in the manubrial vessels was slight and disproportionate to the intensity of the tinnitus aurium, it seemed reasonable to conclude even from these few experiments that the congestion of the deeper cavities was greater than that seen on the periphery, so to speak, of the vascular system, and as the nervous structures within the labyrinth are the undoubted seat of subjective noises, it was probable that the labyrinth was the chief point of congestion.

Recent observations and experiments by Kirchner [3] confirm this view, and show that not only congestion but active inflammation and even hæmorrhage may be produced. These experiments were undertaken upon animals with both quinine and with preparations of salicylic acid, which are well known to produce clinically the same symptoms as quinine. Two gramme doses of sodium salicylate were given to rabbits, cats, and dogs; the number of repetitions of the dose is not stated. The rabbits lived usually about a week, and died with symptoms of great dyspnœa, and with paralysis of the posterior extremities. Dissections showed great hyperæmia of the osseous meatus, near the membrana tympani, with a vesicle containing reddish-yellow fluid, close to that membrane; the tympanic mucous membrane was dull, yellowish in color, and with numerous spots of ecchymoses, varying in size from 3 mm. to minute specks. In a number of cases opening of the labyrinth showed an intense redness on the inner surface of the stapes, and in the vestibule and the end, and periolymph was distinctly colored red. In some of the cases the ecchymoses of the tympanic mucous membrane were present only on one side, while the opposite tympanum showed enlarged and tortuous vessels.

Quinia muriate was given in doses of one to one and one half grammes. Dissections in these cases showed great congestion within the skull, the vessels of the dura and pia being very full, and of ten cases three showed with the enlarged vessels an ecchymosis in the lateral ventricle; similar conditions within the skull were also noted in cases of salicylate poisoning. With cats and dogs one to two grammes of quinia muriate were fatal in from five to eight hours, the animals showing pendulum movements of the head, increased flow of saliva, weakness or paralysis of the anterior extremities, somnolence, rapid breathing, paralysis of respiration, and death. The appearances of the ears on dissection were the same as those seen in the salicylate cases, hyperæmia and hæmorrhage of the tympanum and labyrinth. Precisely similar results were obtained from experiments on guinea-pigs and mice.

"From these observations," Kirchner says, "it is certainly evident that quinine and salicylic acid may produce changes in the important parts of the ear, which may not only injure but even wholly destroy the hearing. The involvement of the labyrinth in the hyperæmic condition could not exist for any length of time without serious injury to the ultimate nerve fibres of the acusticus. The clinical appearances of deafness produced by quinine point to the same thing; usually pain in the depth of the ear is complained of, as was also observed by Roosa, often intermittent, often very severe, and sometimes otitis externa is seen as a complication. In the examination of trustworthy persons who have declared that their deafness was due to large doses of quinine, I have repeatedly seen a marked opacity of the drum membrane, a condition which, as a rule, is to be regarded as the residuum of a chronic inflammatory process, and due to a thickening of the mucous membrane lining the inner side of the drum membrane. The symptoms in the labyrinth are also characteristic and point to an organic change in the ultimate fibres of the acusticus. Just as in syphilis so in quinine deafness we find diminution in the perception of a vibrating tuning-fork placed on the bones of the head, and a defective perception of the higher tones. In quinine deafness we are then dealing not alone with a simple irritation, a simple nervous excitation of the organ which will pass off without leaving injury, but with an inflammatory process and (possible) permanent pathological changes."

[2] American Journal of Medical Science, October, 1874.
[3] Berliner klinische Wochenschrift, No. 49, 1882.

Studies of the pathology of the ear by Toynbee (published 1841-1855), Von Troeltsch, Schwartze, Gruber, Wendt, and many others, all agree in the fact that the mucous membrane of the tympanum is especially liable to inflammation, and the changes found in that membrane, which are the causes of many forms of deafness, are histological changes of the mucous membrane, due to inflammation. The recent work by Politzer [1] gives more thoroughly and completely than has been done heretofore the microscopical changes which occur in the mucous membrane of the tympanum, not only in general, but in each particular part of the conducting mechanism. These observations show, in brief, that while all the structures composing the mucous membrane, epithelium, blood and lymph vessels, nerves and connective tissue, are changed in various ways in the different forms of inflammation, the connective tissue is the part in which the alterations producing permanent impairment of the functions of the conducting apparatus are most common. These changes consist in an infiltration of round cells, which becomes organized into new fibrous connective tissue by which the delicate and movable mucous membrane is converted into a hard, stiff, and adherent membrane, liable with time to a sort of cicatricial contraction, and producing immobility of the parts of the conducting apparatus covered with the affected mucous membrane. This connective tissue is subject also to still further alteration, such as calcification and ossification.

The pathology of the labyrinthine structures cannot be said to be established, the parts lie so deep, are so minute, delicate, and destructible that very few microscopists possess the ability to examine, and fewer still the inclination to devote the necessary time to, this branch of the subject. The extreme delicacy of the parts, however, and daily clinical experience in watching the effects of the common inflammations of the ear upon the nervous apparatus, as shown by the frequent loss or diminution of perception by bone conduction when there is every reason to think that the congestion from the tympanum has extended into the labyrinth, are sufficient to show us that a marked and long-continued congestion of the nervous apparatus is liable to produce serious injury.

The thickening of the mucous membrane observed by Kirchner in cases of quinine deafness is of importance as far as it goes, but too much stress should not be laid upon it, as such opacity may have resulted from some old inflammatory process, dating back even to childhood, as such are very common. It must be granted that no one yet has watched a membrana tympani normally translucent become gradually opaque as the result of quinine, but such a refinement of experimental pathology is scarcely to be expected.

The *rationale* of the action of quinine seems to be almost unknown. Of its effects upon the ear in producing congestion of the tympanum, labyrinth, and osseous meatus I have already spoken, and this congestion, it is fair to assume, is the cause of the well-known tinnitus aurium. Of other well recognized effects we have the frontal headache, with a sense of general fullness in the head, mental disturbance, flushing of the face, suffusion of the eyes, and, Ringer asserts, from large doses, an abolition of reflex action, before voluntary movement, due to stimulation of Setchenow's reflex inhibitory centre. In addition the last two years have developed a quinine amaurosis, serious in its effects on the eye, and still further complicating, rather than explaining, the problem of the action of the medicine. In the *Klinische Monatsblätter für Augenheilkunde*, 1881, Knapp calls attention to sixteen cases of quinine amaurosis, which had been published or which he had himself observed. From 150 to 180 grains taken accidentally at one dose, from nine grains taken every two hours up to seventy-five or ninety grains in the course of one or two days, and from smaller doses taken for from a few days to two weeks great pallor, general weakness, twitching of the mouth and extremities, together with total blindness and deafness, came on. In some of the cases total loss of consciousness for several days existed, and the blindness and deafness were noticed first on recovery from this state. The pupils were dilated and fixed; there was not even perception of light. Ophthalmoscopic examination showed in the most pronounced cases a total absence of blood in the optic nerve and retina. In all of the cases there was a decided paleness of the papillæ, and a narrowing of the retinal vessels, both veins and arteries. The total blindness may remain for weeks or months, but in none of the cases yet observed has it been permanent. The central acuteness of vision in most of the cases returned to normal, in the remainder it varied between $\frac{2}{30}$ and $\frac{2}{200}$. Light and color sense, at first much impaired, gradually became normal in the course of months. Lighter cases are reported by Knapp where, in addition to the more common general symptoms, there were clouding of the vision, diminished perception of color, and narrowing of the field of vision, with pale papillæ and contracted vessels. He has also seen the same symptoms from large doses of salicylic acid and sodium salicylate. From these observations it is evident that in the eye we have an exactly opposite condition from that as yet observed in the ear, anæmia of the retina and optic nerve instead of congestion.

From the observations on these two organs it seems evident that the effect of the drug is expended on the blood-vessels, and is probably due to action upon the vaso-motor nerve centres, although the question of the manner of this action would carry us into the realms of speculation beyond the scope of this paper.

The congestion produced in the tympanum and labyrinth fully explains the fact observed clinically that quinine may increase any existing inflammation of the tympanum. In any ear where there has been a change in the tissues such as has been described, where there is an increase in the tissue elements, and especially of the connective tissue, the result of some previous inflammation, any new congestion or inflammation produces a greater degree of deafness at the time, and is more liable to produce still further tissue changes than if the ear was in a normal state when the inflammation set in. This is due to the fact that the existing hyperplasia in the early stages of the inflammation is increased in volume by a serous infiltration, and in the later stages by an effusion of round cells which, becoming organized, add to the hyperplasia. In the acute secretory forms of tympanic inflammation any increase of the inflammation will of course add to the amount of secretion, and so intensify any previous symptoms. I have already called attention to the delicacy of the labyrinthine structures, and to the ease with which they are injured by inflammations, although the exact pathology has not been determined.

[1] Lehrbuch der Ohrenheilkunde, 1882.

In view of these facts and of the constantly recurring experience that patients refer their new aural symptoms or a decided and serious increase of old aural symptoms to a course of quinine, ought not the ears to be carefully considered in prescribing the drug, and especially in ordering large doses or pushing the medicine to its specific effect of tinnitus aurium? Ought not the existence of inflammation of the ears or of decided tissue changes due to previous inflammations be regarded as contra-indications to large and long-continued doses of quinine, only to be neglected in most urgent cases? It certainly seems to me that more attention should be given to its possible effect upon the ears than is often done.

Of the great value of the drug in an immense number of cases there can be no question; of its absolute necessity in many cases there is scarcely a doubt, but there still remain many instances in which, as I believe, the medicine is given in larger and more continued doses than is necessary for the slight ailments for which it is prescribed, and always with the risk to the ears. Again, there are many instances where the medicine is pushed to its specific effect from indifference or carelessness, where equally good results could be obtained by keeping within the danger line, the tinnitus aurium being the signal given by nature, at least in the majority of cases, of the congestion of the labyrinth. Finally, where large and continued doses are absolutely necessary, and where it is desirable to push the drug to its specific effect, might it not be possible to produce the desired result, and yet occasionally interrupt the administration for one, two, or three days, thus allowing the congestion of the ears to subside? Certainly a continuous congestion for a long time is more likely to result in a decided inflammation with exudation, either free or within the tissues, than an intermittent congestion.

Symptoms of acute inflammation of the ears are well known: earache, fullness, throbbing, often subjective noises, more or less deafness, etc. A few questions from the physician, even if the symptoms are not mentioned by the patient, will bring them to light. With old changes in the ears, the results of previous inflammations, the diagnosis is not so easy. The history of previous pain, severe and long continued, or an otorrhœa of some duration, even if years before, would make one suspect some tissue changes; an existing, although slight, subjective noise of any character, and any degree of deafness in either ear, would also point to the same conclusion. Certainly where any of these symptoms exist the physician should be upon his guard in prescribing quinine, and especially in giving it in large doses.

No fixed rules can be given for doses, for with this medicine, more than with many others, the idiosyncrasies of individuals to the action of the drug are most marked; while six grains in twenty-four hours produce slight tinnitus in one person, many times that amount produce no effect in another individual, and it would be interesting to know whether in the diseases in which very large doses are considered necessary, as, for instance, in severe malaria, the medicine is borne to a greater amount without tinnitus than in the same person when in a state of health.

To formulate the conclusions of this paper, we have, —

(1.) Clinical experience the world over is that quinine occasionally produces serious injury to the ears.

(2.) From our present knowledge, both clinical and experimental, we are justified in asserting that the action of quinine upon the ears is to produce congestion of the labyrinth and tympanum, and sometimes distinct inflammation with permanent tissue changes.

(3.) That the action of the drug upon the ears should always be considered in prescribing it, and changes in the ears, due to existing or previous inflammation of those organs, constitute a contra-indication to the medicine in large doses or for a long time except under urgent circumstances.

(4.) That where large and continuous doses are absolutely necessary an occasional intermission of the administration is desirable, if possible, to diminish the risks to the ears.

RECENT PROGRESS IN THE TREATMENT OF THORACIC DISEASES.[1]

BY F. I. KNIGHT, M. D.

THE CONTAGION OF PHTHISIS.

Dr. C. T. Williams read a timely paper on this subject at the last annual meeting of the British Medical Association.[2] He says that the discovery of the tubercle bacillus, by Koch, and the highly interesting series of experiments which led up to it, have naturally caused us to review phthisis in its various aspects, and especially in that which relates to contagion. How far consumption is infectious is a question which has been under discussion for centuries, and on which great difference of opinion has prevailed, and still prevails, in various countries, the north of Europe holding, as a rule, its non-contagiousness, and the south its contagiousness. The chief difficulty lies in the fact that many of the most potent agents of causation in phthisis, such as dampness of soil, bad ventilation, and deficient food, are also conditions which would promote the multiplication of low organisms; and, on the other hand, heredity, which is the source of a large amount of phthisis, cannot be reconciled in its action with the bacillus theory; for, if a man had strongly inherited phthisis in his tissues, are we to believe the bacilli have been transmitted in the seminal fluid of his father? How can we account for the cases where the parents having died of consumption the children are necessarily attacked, on arriving at a certain age, with a severe type of the disease? [This does not seem to us necessarily an argument against infection. The child may inherit not the germ, but such a condition as makes him, at a certain age, more liable than others to infection, that is, he offers a more favorable soil for the development of the germ. Rep.]

The microscope tells us that Koch's bacilli are present in phthisical sputum in fair abundance. Now, when we consider the number of consumptive people who, being under no restriction, go about coughing and expectorating freely in the streets and parks of London, and remember that this sputa abounds in bacilli, that it dries, and becoming dust is wafted about in the atmosphere, and doubtless inhaled by a large proportion of the population, we must admit that the bacilli, though ever present, are not very active in ill doing, and probably because the soil they enter is not always suitable.

The forms of contagion in phthisis which have been most discussed are the following: (1.) Infection

[1] Continued from page 197.

[2] British Medical Journal, September 30, 1882.

through breathing the same atmosphere, that is, infection by inhalation. (2.) Infection through marriage. (3.) Infection through the milk of diseased animals, or even of phthisical women.

With reference to the first form of infection, Dr. Williams publishes a continuation of the health statistics of the Brompton Hospital resident staff. It will be remembered that the late Dr. Cotton, in the year 1867, published a report of the health of the residents from 1846, the year in which the hospital was opened. The two together form a set of statistics extending over a period of thirty-six years, and relating to several hundreds of individuals subjected more or less to contact and association with consumptive patients for periods varying from three months upwards. The hospital commenced in 1846 with ninety beds, which, in 1856, were increased to 200. In 1873 a temporary utilization of the ordinary dwelling-houses, which stood on the site of the new building, raised the number of new beds to 240, which was maintained till 1879, when the temporary wing was closed. At present there are again about 240 beds in use, funds being as yet wanting to allow the whole number of 337 to be maintained.

The ventilation of the hospital is now carried on by extraction, by coils of steam pipes placed in towers in different parts of the building, the air being changed two or three times an hour. There is, in addition, extraction by the fire-places. Admission of air takes place at one wing at the level of the galleries and wards; in the other at the basement, the air being heated in winter before admission. Previous to the introduction of the extraction system, in 1877, the left wing was ventilated most imperfectly, and the impure state of the air showed itself in an outbreak of erysipelas and sore throat in 1869, and again in 1875. Since 1877 the extraction of foul air has been well performed, and as long as the proper difference of 10° F. between the shaft and the wards is maintained, all goes well; whenever, through accident or other causes, this extraction rate has been diminished, sore throat has appeared in some of the wards. Three fourths of the patients are cases of phthisis in various stages and forms; in many this disease is very advanced, accompanied by pyrexia or loose expectoration, or by both.

The rest of the patients are instances of other forms of chest-disease, such as pleurisy, empyema, bronchitis, chronic pneumonia, bronchiectasis, and emphysema, or else of diseases of the heart. The spittoons of the patients are changed two or three times a day; but until lately, unless the odor was unpleasant, no attempt was made to disinfect them.

It seemed to Dr. Williams that the above facts are instructive as bearing on the bacillus question. The deficiency in the ventilation must have led to a large accumulation in the wards of the products of respiration, and also of our friends the bacilli; we consequently ought to have seen an extension of the disease to non-consumptive cases or to the nurses; but nothing of the sort occurred, only the usual results of hospitalism, that is, erysipelas and sore throat.

The out-patient department was until last winter situated in the old hospital, and was quite insufficient properly to accommodate the large numbers of out-patients attending. The ventilation was exceedingly bad, and communication with the dispensary being made by windows, the air of that department was rendered more impure. The attendance of two to three hundred out-patients daily, of whom a large proportion were consumptive, must, on the theory of infection, have proved a considerable source of danger to assistant physicians, to the clerk who enters their names, and to the porters who marshal them and keep order.

There have been four *Resident Medical Officers*. All are alive, and tolerably well. Mr. Edwards held the post for twenty-five years without any symptom of lung disease, and still enjoys good health. Of the others, two showed at some time of their residence signs of hospitalism, but none of definite consumption.

Clinical Assistants. — These are senior students or qualified medical men who reside in the hospital for six months, and are engaged in the treatment of patients and the recording of cases. They also assist the pathologist in making the post-mortem examinations. About 150 have held office since the opening of the hospital; of fifty-nine Mr. Edwards reported, in 1867, that three had become consumptive, and of these fifty-nine one more has since contracted the disease. Mr. Edwards states that all were free from phthisical disease during their residence in the hospital. Of the sixteen before Mr. Edwards's time one who had strong family predisposition died of phthisis. Of the seventy-five who have held office since 1867, Dr. Williams has traced all but three. Of these seventy-two one has died from other causes than phthisis; two have died of consumption, one case having had hæmoptysis previous to residence, and in the other the disease came on one if not two years after residence, the gentleman being quite well during his term of service. Another, who was overworked, became consumptive while in the hospital, but has since entirely recovered. The remaining sixty-nine are all well. Therefore, of the 150 eight became consumptive at some time or another of their lives, and five died; but in only one instance was it clearly proved that the disease was contracted in the hospital.

Matrons and Lady Superintendents. — Of these there have been six, none of whom suffered from consumption. One lady held this post twenty-four years. All are alive except one, who died at an advanced age.

Nurses and Servants. — The head nurses or sisters sleep in rooms communicating with the wards through the galleries, and during the day their duties bring them constantly into contact with the patients. The assistant nurses sleep in bedrooms above the wards, but practically live in the galleries and wards, being engaged either in day or night nursing.

Among the nurses, up to 1867, Mr. Edwards reported one death from apoplexy, and one from phthisis, the disease being in this case contracted under conditions of great poverty after she had left the hospital. Since his report some of these nurses have died — one of cancer at fifty-two; one of chronic pneumonia preceded by erysipelas, chronic rheumatic arthritis, and enlarged cervical glands. Three have died of phthisis after leaving the hospital, two of whom were quite free from chest symptoms while resident, and were not attacked till many years later. In one case the disease seems to have commenced while she was a nurse; this is the only one in which consumptive disease came on in the hospital among the nurses, and this in a period of thirty-six years. Since 1867 there have been 101 nurses, three of whom have died, one was drowned at sea, one died of poisoning, and one of phthisis after leaving the hospital, but there is no evidence of her having contracted it there.

There is a small institution called the "Home" in

connection with the hospital, where male patients wait their turn for admission. It is an ordinary dwelling-house of ten rooms, with no arrangements for artificial ventilation, and often contains twelve to fourteen inmates. It has been open about twenty years, and during this period there have been four matrons, all of whom have enjoyed good health. Of the thirty-two gallery-maids, scrubbers, who have served since 1867, many cannot be traced, but no death has been ascertained, and certainly no case of phthisis occurred among them while in the hospital.

House Porters. — Of these there have been twenty, including the gate and out-patient porters. Their duties in the waiting-rooms expose them to the breath of the out-patients. None, as far as known, have died of phthisis.

The following are non-residents: —

Physicians and Assistant Physicians. — There have been twenty-nine, of whom eight have died, but only one from phthisis. The duties of the assistant physicians keep them for many hours at a time in close contact with a large number of consumptive patients, and it is difficult to see how they can avoid, in the course of a careful examination of the chest, inhaling a certain amount of the patient's breath.

Dispensers. — Of these there have been about twenty-two; seven have died. One committed suicide, one died of liver disease, two of pneumonia, three of phthisis; of these last one became intemperate, left the hospital, and, being in wretched circumstances, died of consumption two years after leaving. A second left the hospital well after two years' residence, but after going into business contracted phthisis and died. In the third the lung disease appeared during the three years he was at the hospital. One dispenser, who held office for two years, and afterwards went into business on his own account, was admitted for phthisis twenty-five years later, and is still living. There were also two dispensers who showed distinct signs of consumptive disease, but entirely recovered, and are now in good health. These dispensers have no duties in the wards, but, as before mentioned, the over-crowded out-patient in the old hospital communicated with the dispensary by two windows, and the air of this department, already insufficient, was thus further vitiated.

Chaplains. — Of these there have been four. One died of heart disease, two at tolerably advanced age, not of lung disease. The present chaplain has been there eight years, and enjoys excellent health. He has no other duties than in the hospital.

Secretary and Clerks. — Of these there have been nine, of whom three have been threatened with lung disease, but have recovered.

A consideration of the above statistics, furnished by the largest institution for the treatment of consumption in the world, will lead us, as Dr. Cotton says, to hesitate before classing phthisis among the infectious diseases in the ordinary sense, for such an amount of phthisis might be found in any large institution not specially devoted to consumption; nay, more, in any large mass of town population.

NITRO-GLYCERINE IN ANGINA PECTORIS.

A valuable addition to our resources as therapeutists seems to have been made by Dr. Murrell. Many of our readers are familiar with the cases of angina pectoris treated by nitro-glycerine reported by Dr. Murrell in the *London Lancet* in 1879. Dr. Murrell now gives us the results of his more extended experience in a little brochure.[1] The symptoms following a dose of two drops of a one per cent. solution are slight flushing of the face, decrease in the fullness of the arteries, and a rise in the pulse rate. One of the most uncomfortable symptoms is the feeling of pulsation in the head. Sphygmographic tracings are given showing the effect of the drug on the pulse. The tracings as well as the symptoms are similar to those produced by the nitrite of amyl. Both drugs produce a marked state of dicrotism, and both accelerate the rapidity of the heart's action. The nitro-glycerine produces its effects much more slowly than the amyl nitrite, and they last longer. Some interesting observations were made during the administration of nitro-glycerine to a patient with epispadias, showing a greatly increased flow of urine.

Dr. Murrell has given nitro-glycerine in many cases of angina pectoris with marked success. Details of a dozen cases are given.

From a study of his cases Dr. Murrell draws the following conclusions: —

Mode of Administration. — The author generally uses a one per cent. alcoholic solution, one minim being equal to one hundredth of a grain of pure nitro-glycerine. It may be given in a teaspoonful or more of water. In some cases he has given it with a few drops of spirits of chloroform in peppermint water, an advantageous mode of administration when anything cold excites or intensifies the paroxysm. It also relieves the flatulence which often accompanies the attack.

The Dose. — On this point it is impossible to lay down any definite rule. One patient could take over one hundred minims of the one per cent. solution at a dose, whilst another suffered severely from half a minim. As a rule one minim is a safe dose to begin with, but it is better to begin with half a minim. Murrell says he nearly lost a patient by giving him two minims for the first dose. Although it is a good plan to begin with a small dose, there is no reason why it should not be increased rapidly. If half a minim produces no effect, give a minim at once, and go on increasing the dose till the patient complains. It must be remembered that the object is not to give a certain dose, but to get the physiological effect of the drug. After a time tolerance is established and the patient is able to take more than at first. An overdose might produce alarming symptoms, but the effects are commonly transitory, and the patient recovers before assistance can be obtained.

Frequency of Administration. — Murrell generally gives a dose every three hours, with an extra dose immediately at the onset of an attack. The patient should always carry the medicine with him. It should be remembered that when the attacks are severe, it may be necessary to give dose after dose in quick succession until relief is obtained. The full physiological action on the pulse as shown by the sphygmographic tracings occurred six or seven minutes after the dose.

Safety of Nitro-Glycerine. — The one per cent. solution is perfectly safe, and may be used without fear.

— At a large antivivisection meeting recently held at Manchester, England, three resolutions successively proposed by the originators of the movement were voted down, owing to the effect of a temperate speech on the aims of physiologists by Professor Gamgee, who was present.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

FEBRUARY 12, 1883. DR. CHARLES D. HOMANS presided.

DR. S. G. WEBBER read a paper on

OCULAR SYMPTOMS AS LOCALIZING SYMPTOMS.[1]

DR. H. W. WILLIAMS said that it is extremely interesting to read cases followed up so thoroughly, this not being usually the case, and to see the use that had been made of the ocular symptoms, not ophthalmoscopic, the movement of the ball and pupil, not the symptoms of the fundus as seen in other lesions.

DR. J. J. PUTNAM called attention to the rising temperature in all these cases. He asked how Dr. Webber explains the headache, whether from hæmorrhage, occlusion of vessels and anæmia, or otherwise.

DR. WEBBER said that it came from intermittent blood supply or from pressure on the meninges, which are well supplied with nerves. He supposes there is such a thing as anæmic headache. The blood-vessels were not occluded in any of these cases where headache existed. That symptom was most marked in the case of tumor.

DR. WADSWORTH asked whether conjugate deviation of the eyes, lasting only for a short time, and entirely disappearing, had been observed.

DR. WEBBER did not remember any case where the conjugate deviation disappeared, the paralysis of the limbs persisting. In the third case reported both paralysis of the limbs and conjugate deviation were temporary, and recurred several times.

FEBRUARY 26, 1883. DR. CHARLES D. HOMANS presided.

DR. J. ORNE GREEN read a paper on

THE ACTION OF QUININE UPON THE EAR.[2]

Dr. Green said that attention had been called to the same subject by the paper of Roosa, and that he was happy to indorse it.

DR. FIFIELD thought the paper of Dr. Green most timely. He had noticed with astonishment and alarm the enormous doses of quinine and salicylic acid ordered by young men fresh from the schools. They seem to have been taught that high temperatures are to be fought in the most determined way, forgetful of the fact that temperature and pulse are by no means the essential factors of disease, and although one may be lowered, and the other lessened in frequency, yet the fatal result is not stayed. St. John Roosa, in his recent paper upon quinine, had made this point, and it had been well made. Dr. Fifield thought the reintroduction of the thermometer had been by no means an unmixed blessing. High temperatures alarmed us sometimes unnecessarily, when if we had not known them we should have thought the patient going on well. He alluded to the former great sage for reducing the rate of the pulse by veratrum viride, when physicians claimed to jugulate pneumonia by its use, as they now talk of doing the same thing by quinine and salicylic acid. Norwood's tincture was the great god of medical idolatry. Who prescribes it now?

Dr. Fifield related the following case of a young man ill with erysipelas of one arm: The pulse was about 120, temperature 104.4° F. At four P. M. the administration of salicylate of sodium was begun, ten grains every two hours. Orders were given to take temperature by rectum every two hours, and when the temperature should fall to the neighborhood of 100° F. to stop medicine. The following morning at four o'clock it had fallen to 99° F. Medicine suspended; pain relieved. The same day at noon temperature began to rise, and by four P. M. had reached its old standard, 104° F. Salicylate of sodium in same doses resumed; same orders. At four A. M. temperature again fell to nearly normal. Medicine suspended; pulse about 84. At ten o'clock that morning, whilst eating breakfast, the nurse noticed that although he continued to eat, yet he ate more and more slowly, answered questions more and more slowly, and seemed falling asleep, or becoming more and more unconscious. She then saw that the finger-nails had turned blue, then that the pulse had ceased. Mustard and hot water over the præcordium, stimulants internally, with hot bottles to feet, etc., revived him, and the temperature rapidly shot up to its old point of 104° F.; pulse 120. All medicines having been suspended the temperature remained at the point mentioned until four A. M., when it fell rapidly to 99° F., remaining so for the next twenty-four hours; pulse at 80. The next day, in the afternoon, temperature rose to 104° F.; fell after midnight to normal, and thenceforth never rose again. Convalescence now became complete.

The fullest and most satisfactory account of salicylic acid in its action on the animal is contained in H. C. Wood, Jr.'s Treatise on Therapeutics. In this we are told it manifests its presence in the system by symptoms closely resembling cinchonism. In large doses there is distress in the head, a positive headache, deafness, amblyopia, excessive sweating. According to Reiss decided fall of temperature without alteration of the pulse also occurs. The action upon the system of the acid and its sodium salts appear to be identical, ptosis, deafness, strabismus, mydriasis, disturbance of respiration, excessive restlessness, passing into delirium, slow, laboring pulse, olive-green urine. In some cases the temperature has remained normal, in others it has approached collapse. One fatal case is recorded in the *Virginia Medical Monthly*, June, 1877. Forty-eight grains of acid were taken in four hours. The symptoms were violent vomiting, headache, stertorous breathing, total unconsciousness. Death occurred forty hours after the first dose. A strong tendency to sleep is mentioned.

Temperature in normal men and animals seems to be unaffected by even large doses of salicylic acid.

Dr. Wood says of the drug: "The well-known physiological action of salicylic acid would only lead to one use of it in internal medicine, namely, as an antipyretic. The question as to whether good is achieved in fevers by its administration is of course entirely separate from its power of reducing temperature. It is certainly possible for a drug to lower fever heat, and yet to do far more harm than good, and the evidence at hand is insufficient to answer the inquiry." The case cited shows how easy it is to become the victim of a fallacy. Roosa, in his paper, points out that the

most brilliant examples of reduction of temperature by large doses of quinine have been followed by death just when, judging by the thermometer, they should have got well.

Dr. H. W. Williams said that it seems an enigma that the ear should be congested while the eye is anæmic. He supposes malaria may have some effect in altering the conditions. The state of the optic disk may depend in part on the general condition. He has seen this blindness only after long courses of large doses, mostly from the West. There has been slow recovery.

Dr. Lyman thought the paper a very timely one in view of the large doses of quinia and the salicylates now so very commonly given. He could not agree with the views of Dr. Fifield as to the little importance of high temperatures in disease. The use of large doses constantly repeated was, in his opinion, very objectionable, but in acute disease he felt quite sure of the beneficial results of one large dose, say ten or fifteen grains of quinia, when the temperature was high, given daily and repeated if necessary for several days. Had rarely if ever seen it followed by tinnitus, more often by nausea. If there was any tendency to cerebral congestion, he was in the habit of combining it with bromide of potash. In hospital cases, such as typhoid or pneumonia, as the remedy is only used at the height of the disease, the patient usually remains long enough during convalescence to show the evil effects of the remedy upon sight and hearing should such occur. He had never as yet seen such effects. He was not much in the habit of using quinine as a tonic, finding other things more beneficial. He had, however, seen more disturbance from its use in small doses long repeated than from the occasional use of large doses.

Dr. Hodges said that much of his knowledge of quinine was derived from observation of its effects when self-prescribed by patients, especially for the cure of "colds." By their own admission this was with an almost invariable result of aggravating the headache and coryza, and adding to the general irritation, without affording any compensatory benefit.

The temporary suppression of neuralgic pain which, with many failures, occasionally follows the administration of quinine, suggested the question whether similar relief might not have been obtained as promptly, and more agreeably and safely, by the use of some other drug. The equally transient, and perhaps unavailing, fall of temperature which succeeds the giving of large doses of quinine attracts attention and fixes itself in the memory; and yet the numberless times when the drug fails to produce this result are probably more familiar to physicians than the successes.

Apart from its use in intermittent fever, of which the speaker had no experience, the exhibition of quinine, so far as his observation had enabled him to judge, was attended by no beneficial or well-established effects whatsoever, other than its toxic ones, but by a great many discomforts, as well as by the dangers to which the paper of Dr. Green had called attention.

Dr. F. W. Draper remarked that the very valuable and instructive observations set forth in the paper would, he believed, possess much additional significance if they were supported by data from the reader's clinical experience as an aural surgeon showing a real increase in the number of cases of permanent deafness, attributable to the use of quinia, and occurring coincidently with the recently developed medical fashion of using large and sometimes intemperate doses of that drug. He agreed with Dr. Lyman in defending quinia as a therapeutic agent of great value, and he had never seen or heard of a case in which permanent injury to the hearing was directly traceable to its use.

Dr. Green said that he does not get an increased number of cases in which he is certain that quinine is the cause. He thinks that patients are less inclined to complain of deafness during convalescence, and later we do not always get the history.

Dr. C. J. Blake thought the paper timely and important. He then referred to the possibility of mistaking the effect of typhoid upon the middle ear for the effect of quinine.

Dr. Edes said that years ago he had been familiar with moderate quinine deafness in patients and to some extent in his own person, and had taken much interest in the question of permanent deafness, which he had been led to believe a rare though perfectly well recognized accident.

Facts of this kind, as well as of amaurosis, are reported in the elaborate work of Briquet, 1855, all occurring after large and usually continued doses. Dr. Edes had inquired some years ago of several aurists, among others of the reader, and could get no account of more than one or two suspected cases. A friend, who as a naval surgeon had had occasion to use the drug in considerable quantities, and who after the war devoted himself to aural practice, was so kind as to make an inquiry for such cases in the New York Ophthalmological Society, and elicited the opinion from several members, some of whom had had large hospital experience with malarial cases where quinine had been used very freely, that this drug was rarely if ever a cause of permanent deafness. Briquet mentions several physicians using large doses who do not report cases of permanent deafness, and speaks of Maillot, who used quinine in large doses in more than six thousand cases, as stating that the deafness always disappears at the end of a few days. He himself makes the same observation.

Dr. Edes wished to call attention to the size of the doses administered to the animals mentioned in Dr. Green's paper as presenting inflammatory aural lesions. If a cat weighs five pounds and a man one hundred and fifty, a dose of one gramme or one gramme and a half to the former animal would be equivalent, according to their relative weights, to thirty or forty-five grammes, or one ounce to an ounce and a half of quinine to a man.

Briquet remarks that "when one is obliged to carry the sulphate of quinine beyond two grammes it is always well to assure one's self of the previous condition of the eyes." Dr. Green's paper shows that the same warning may be applied, perhaps more forcibly, to the ear.

Dr. J. J. Putnam said that relief of aural vertigo and increase of deafness have gone hand in hand, seeming to show that quinine affects nutrition in these cases. It is an interesting pathological question if pure congestion, unless long continued, can produce tissue changes. Quinine affects the white blood corpuscles beside causing congestion. While caution is desirable it should be said that we do get failure from too small doses in cases that yield to large ones.

Dr. Baker had very often given thirty to thirty-six grains daily for many days. His cases were of a class that remain under observation a long time and

often return, but he knew of no bad effects. He had seen deafness and blindness from thirty-eight grains in an hour, but it passed off in a few days.

DR. GREEN said his paper was meant merely as a caution against the abuse of the drug. Most of the cases get well, but some do not.

DR. FIFIELD spoke of a recent discussion at the London Pathological Society on

ACUTE DILATATION OF THE STOMACH OCCURRING IN SURGICAL CASES.

He had himself had a case of an opened knee-joint, with burrowing of pus, the result of accident. The case had been at first mismanaged by an irregular, but seemed otherwise well, until vomiting began suddenly. The patient continued to vomit green watery matter for three days, when he died.

Post mortem by Dr. Gannett. Stomach greatly distended, reaching almost to the pubes. Contents in part gas, and also a litre of a greenish, stringy, thick fluid. Walls very thin; mucous membrane opaque and covered with an abundant layer of thick, tough mucus. Pylorus admitted four fingers easily. Duodenum and upper part of jejunum considerably distended above normal; remaining portion of intestine constricted and empty. Mucous membrane of intestine not unusual. There is no history of dyspepsia, and there was no disease of kidney, but the man was very nervous and anxious.

DR. MINOT reported a case of a woman, single, thirty-two. Two years ago pain in epigastrium after food, often for several hours. About the same time diarrhœa, lasting up to Christmas, 1882. Vomiting for a year past, at first at long intervals, of late every three or four days. Some swelling of feet and legs, which disappeared, but returned markedly in the last three weeks. Three months ago pain in left side just below nipple. Afterwards darting pain in lower abdomen at intervals. Scar in lumbar region as of a cut and sutures.

Operation denied by family; abundant growth of hair in vicinity of cicatrix. Thirty-six hours before death severe pain in lower abdomen, followed by great tympanites.

DR. FITZ stated that death was the result of acute peritonitis, due to a perforating, apparently tuberculous ulcer of the cæcum, and showed the diseased portion of the intestine, which was particularly interesting from the evidence it presented of the tendency towards and the possibility of a complete healing with cicatrization of tuberculous ulcers of the intestine.

There were several ulcers of the lower third of the ileum, both girdling and rounded, the latter opposite the mesenteric attachment. All were deeply pigmented, extremely puckered and indurated, and were partly covered with irregular patches of mucous membrane. Neither in the bases nor edges were appearances seen suggestive of tubercles. Six annular stenoses, the smallest less than a quarter of an inch in diameter, were present in the vicinity of the ulcers. The intestine above these was dilated, its walls were hypertrophied, and the mucous membrane was speckled from pigmentation.

Over the constricted portions of the intestine the mucous membrane, for the most part, was entire.

The cæcum was contracted from the presence of an extensive, chronic, pigmented ulcer, traversed by bridges of tissue. A small perforation through the edge of the ileo-cæcal valve established a second opening between the cæcum and ileum. A pin-hole opening through the cæcum at the outer and posterior portion was covered externally with a layer of fibrine uniting the cæcum to the abdominal wall behind.

At the junction of the ascending with the transverse colon was a large trabeculated ulcer with occasional gray and cheesy specks apparent in sections through the base. The lumbar and several of the mesenteric lymph glands were enlarged and cheesy. No evidence of tubercles was found elsewhere than in the ulcer of the colon and the abdominal lymph glands. The femoral and iliac veins were completely obstructed by thrombi, which were continued into the inferior vena cava as far as the renal veins. The linear cutaneous scar in the lumbar region was not connected with any apparent deep-seated lesion.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, RECORDER.

THE MORPHOLOGY OF PULMONARY PHTHISIS.

BY DR. EDWARD T. BRUEN.

I have been requested by the committee of arrangement to present some considerations bearing upon the pathological anatomy of phthisis, as the basis of a discussion of the subject before the Society. The ætiology of phthisis is very properly exciting careful attention at present; but the subject is in a far too unsettled condition to permit even a useful discussion. I shall not therefore allude to it, and I feel that I must offer an apology for the triteness of the subject-matter of my paper; but I was informed that it was designed to have a series of discussions upon *familiar* pathological conditions. With this understanding my scruples have been overcome. A consideration of special interest seems to me to be connected with the morphology of primary tubercle. In certain individuals, owing to inherited tendency, or particularly unfavorable surroundings, recovery after bronchitis due to cold is retarded, or a susceptibility to a new bronchitis is increased. In either case lingering catarrh in the majority of instances is the inception of the series of pathological processes known as phthisis pulmonalis. Two macroscopical appearances, nearly identical, occur, but they differ materially in their microscopic anatomy. Certain so-called miliary tubercles are frequently composed only of the inflammatory products of connective tissue, without the characteristic true tubercular arrangement. The word miliary expresses their appearances, but the inflammatory products may be so arranged as to represent true tubercle, pseudo-tubercle, or a diffuse inflammation. This tubercle or pseudo-tubercle is constant in the different forms of phthisis in the adult, except in the instance of pure interstitial pneumonia. Frequently the amount of tubercle tissue in the lungs is so great as to form the principal part of the process, although complicating inflammatory cheesy products are also present.

Classification of Phthisis. — The term tubercular peri-bronchitis is probably the best for the earliest stage of phthisis, and sometimes is the best to designate the process all the way through. The appearance of the peri-bronchial tissues resembles berries on a stalk. The formation extends along the bronchi, spreading from acinus to acinus until the trunk is reached, and is also distributed in the sheaths of vessels and lymphatics. True tubercle may penetrate a bronchus and involve the lining membrane, and a true

tuberculous ulcer may form the basis of an extensive associated bronchitis. Aside from this these infiltrations excite inter-lobular connective tissue growth, and subsequently the walls of the vesicles become thickened, and some vesicular catarrh ensues which may occlude a lobule. Thus the three divisions of the pulmonary tissue share in the pathological process of early phthisis. The cause of more than nineteen twentieths of vesicular consolidation is the result of a process of desquamative pneumonia. This term is used to describe the diffuse inflammation which may accompany the former processes, and which, more than the other changes, paves the way for the disintegration of the lung. In this process the peripheral epithelial cells of the bronchi are proliferated and shed, thus filling the bronchi and infundibula, while the surrounding connective tissue becomes infiltrated with cells. In children this process is a common one on account of the greater cellular activity in these subjects. In the desquamative catarrhal pneumonias of early life the process differs from the desquamative pneumonias of adults in that the air cells only are filled, and there is little or no change in the intervesicular tissue. Hence it is that recovery is so much more frequent in children than in adults. This process of desquamative catarrh is the basis of those cases of acutely developed phthisis which follow croupous or catarrhal pneumonia, and which has been called acute catarrhal phthisis or galloping consumption — sometimes pneumonic phthisis. When the pathological process just described is less rapid, the result which follows has been classed by some as acute caseous pneumonia. When the changes are still more slowly developed, it is synonymous with the chronic catarrhal pneumonia. The relative development, then, of these processes known as phthisis in the three divisions of the pulmonary tissues, the bronchial, the inter-lobular, and the vesicular, is dominated by the activity of the inflammatory process. Peri-bronchitis with consecutive changes in the latent forms, desquamative pneumonia in the more acute forms. While a process presently to be alluded to — interstitial phthisis — occurs as a very slowly developed change. In many of these cases when the destruction of the lung is very rapid the tubercular deposition, true or pseudo, occurs in early stages, but is masked in the later by the development of the secondary inflammatory desquamative pneumonic processes.

The situation at which phthisis is developed is probably most frequently the apex. The forces of expiration presumably are least efficient at this site, and the lungs are less entirely freed from mucus. The circulation also is less than at the roots, and the products of inflammation are therefore more dry. The roots of the lungs, however, in a large minority of cases, are primarily affected. This is especially true of cases in which the original processes of invasion are latent. I pause here to observe a clinical point of some interest, namely, that when the area of lung involved in the process of phthisis is distinctly limited, and does not shade off gradually into healthy lung, my opinion is that a favorable result may be very possible. Certainly I have seen the process of phthisis arrested even when it had passed into the stage of cavity when the lesions were sharply defined. The localization of a lesion, other things being equal, is a point of favorable prognosis. Another topic of interest is the share taken by pleurisy in the development of phthisis.

A specimen already exhibited before the Society is again shown to-night. It is taken from a colored man, seventy years old, with a family history free from the taint of pulmonary disease. He was tapped five times for the relief of hydro-thorax due to heart failure. Each paracentesis was followed by an exacerbation of pleurisy. Nine months after the first operation death occurred from an increase of hydro-thorax. The autopsy disclosed general miliary tuberculosis of the pleura and secondary deposits in the viscera. Throughout the parenchyma of the lung, adjacent to the pleura, there was copious deposit of tubercle, but the other parts of the lungs were normal.

Another specimen exhibits the same tendency, namely, general pleurisy, with phthisis and cheesy deposit in the pulmonary parenchyma, with cavities. The deposits are most abundant near the pleural surface of the lung, the deeper parts evidencing a more recent date formation.

These specimens show that pleurisy may give origin to a tuberculous inflammation. But while this is true it is conceded by all that dry pleurisy is a frequent secondary lesion in progress of pulmonary tuberculosis. Pleurisy is, however, in many cases very conservative, since by the thickening and adhesion of the pleural surfaces, the ulceration of the walls of superficial cavities is arrested and pneumothorax is prevented.

Interstitial Phthisis or Cirrhosis is a process in which true or pseudo-tubercle may or may not be associated. The pulmonary tissues are traversed by narrow bands of connective tissue which may gradually compress it more and more, finally converting it into dense fibrous masses. The color of the lung is apt to be slaty and dark. However, in some cases of interstitial phthisis patches of the peri-bronchial and desquamative pneumonia may be found with cheesy degeneration. Interstitial formation is an important part of the process by which cavities are inclosed and sometimes cicatrized.

Distribution: interstitial phthisis, if consecutive to bronchitis, is usually bilateral, affecting the upper lobes, although as a unilateral affection it is not infrequent.

Syphilitic Phthisis. — It is of interest to notice in this connection, that the early lesions of syphilitic phthisis, so called, are evoked very often by bronchial catarrhal inflammation, which predisposes to structural changes. In these cases there is a principal interstitial fibro-nuclear growth, commencing in the alveolar wall and concentrically arranged around the smallest bronchi and pulmonary vessels. Wagner maintains that the alveolar wall is implicated as commonly in syphilis as in ordinary phthisis. Bronchial narrowing occurs in these cases by the pressure of the new growth which develops along their lumen. Bronchial occlusion may occur from this new formation, but it is also caused by the enlarged bronchial glands, one of the effects of syphilis. By this means serious mischief in the lungs may be developed. In kind proportioned to the degrees of obstruction, such as atelectasis, emphysema, and certain forms of pneumonia, Green and Virchow suggest that the origin of syphilitic diseases of the lung is distinctive in this respect; that while in ordinary phthisis the fibroid is secondary or co-equal in its development with changes in the alveoli and alveolar wall, in syphilis there are primarily principal interstitial changes. Later, when entire vesicular consolidation and breaking down occurs, the process is similar to ordinary phthisis, and indistinguishable from it. The

vascularity of the new growth of connective tissue is also claimed to be a distinctive characteristic of the inflammatory proliferation due to syphilis. But we must remember in any discussion of early syphilitic lung disease that the one special and characteristic lesion of syphilis is the change in the intima of the blood-vessels. This has not yet been demonstrated in the lung, but merely general thickening of the external coat of the vessels. In the effect of interstitial processes upon the bronchial tubes the syphilitic differs from the non-specific diseases. The tough, contracting, fibrous, tissue which radiates through the lung draws together the bronchial tubes and deforms by narrowing or flattening them, possibly even to obliteration. On the contrary, in the forms of non-syphilitic fibroid phthisis the bronchial tubes are widened. The process proceeds in syphilis from the hilus into the interior of the lung, following the tract of the bronchial radicals and the bronchial arteries. The lesions also occur on the surface, near the visceral pleura, where there is also more connective tissue. Gummata occur as a later process. Time will not allow me to allude to these as I should like. A demonstration of the pathology of phthisis would be incomplete without concluding some cases of true miliary tuberculosis. This process may be primary in the lungs or secondary as a part of the general infiltration of the serous and mucous membranes, the lymphatic glands, and the viscera. This form of tubercle is characteristically recognizable only in the miliary stage. Its appearance as a number of small, hard, translucent nodules is too familiar to need description. A specimen upon the table illustrates an extensive lymphangitis of the pulmonary pleura forming a net-work over the pleura. The process microscopically shows adenoid tissue in nodular form. Similar cases have been described before the London Pathological Society in 1880.

Enlargement of the Bronchial Glands. — Another important part of the phthisical process is the enlargement of the bronchial glands. They present a firm pigmented character, and the connective tissue is usually infiltrated. I have observed in many cases in individuals suffering from temporary catarrhal conditions of the bronchial mucous membrane, especially when there is a family history of inherited phthisis, but particularly in distinctly scrofulous persons, a set of symptoms referable to enlargement of these glands. These symptoms consist chiefly in an alteration in the rhythm of the breathing, presumably from pneumogastric irritation is apparent inability to fill the chest with air, and a sense of suffocation is complained of. Added to these these is *pain* in the back to the right or left of the second dorsal vertebræ. Further detail of the clinical ensemble would carry one away from the pathology of the subject. When the enlargement of the bronchial glands is excessive it may occasion severe mediastinal pressure and pain becomes an important clinical symptom, and is of the sort occasioned by mediastinal growth generally. To detect this enlargement during life Guineau de Mussy has suggested percussion over the spinous processes of the cervical vertebræ in the course of the trachea. Following this line in healthy subjects a distinct tubular sound is elicited by percussion down to the point of bifurcation of the trachea at the level of it. Opposite the fifth and downwards we get the lower pitched and pulmonary resonance. When the tracheal or bronchial glands are enlarged the tubular sound over the upper dorsal vertebræ is replaced by dullness, which may contrast sharply above with the tracheal and below with the vesicular resonance. The result of bronchial pressure upon the pulmonary tissues is best marked when the processes of phthisis are not too extensive, also in interstitial phthisis, or in cases where there is marked bronchitic complication. In these cases the lumen of the bronchi are seriously diminished, and vesicular air supply is interfered with. Consequently emphysema with or without asthma atelectasis or a very intractable bronchitis may occur.

I will not describe the morbid process of phthisis in detail. The involvement of an entire lung is simply the filling up of the parenchyma with peribronchial product, or with the results of the desquamative pneumonic or interstitial process. And as one or the other of these predominate, so do we have peribronchial, fibroid, or catarrhal phthisis.

Another interesting although not demonstrable incident in the pathology of phthisis is hæmorrhage. Bleeding from the lungs occurs both early and late in the history of cases. The late hæmorrhage is easy to explain, being nearly always due to ulceration of the blood-vessel walls. The cause of early hæmorrhage is less simple; it is possible that in cases of phthisis there may be malnutrition or fatty degeneration of the blood-vessel walls, rendering rupture under conditions of increased arterial tension in the lungs an easy circumstance. It may also be the result of tubercular infiltration of the muscular walls which is followed by rupture of the blood-vessels.

Cavities in Phthisis are the result of several processes. They occur by (*a*) a slow or rapid process of fatty degeneration followed by ulceration; (*b*) as the result of chronic bronchitis and softening of bronchial tissue, with subsequent yielding to traction from without, for instance, in broncho-pneumonia or fibroid phthisis; (*c*) abscesses as a sequence of acute lobar pneumonia following hepatization or purulent infiltration; (*d*) as the direct result of gangrene, itself the immediate consequence of wounds of the lung, or blood poisoning, or of emboli. Local gangrene, on a small scale, occurs sometimes around cavities in lungs or in the bronchial tubes, and may give rise to temporary fetor of breath, but is not likely to lead to fallacious inferences, chiefly because of its temporary character, and the absence of permanent concomitant symptoms. It naturally follows that there are two locations for vomical, the pulmonary and bronchial tissues. Specimens illustrating the various forms of cavities are upon the table.

The limits of a paper designed to open a discussion on phthisis will not permit me to dwell upon the bearing of these pathological changes upon physical diagnosis. I therefore will close with a brief résumé of the general clinical symptoms which define the diagnosis of the various sorts of cavities. *Phthisical cavities* commonly are situated in one or both lungs, and are indicated as a development in a train of symptoms, which include as prominent features gradual emaciations, persistent loss of weight by reason of mal-assimilation of food, more or less frequent hæmorrhage and hectic, frequent pulse, hacking, intermittent cough, nummular sputum, expectorated in varying amounts throughout the twenty-four hours, and not periodically, as in bronchial dilatations, nor inaugurated by a gush of pus and mucus, as in abscess. *Cavities of the nature of abscesses.* The pathology of these cavities,

with its coincident clinical history, is not that of phthisis. The history of these cavities is either recovery by contraction (especially after wounds) or more frequently the abscess grows larger and larger until the entire lung may be destroyed, in this respect resembling phthisical cavities. When death occurs it is by exhaustion and hectic, where recovery takes place it is by free opening externally or internally and evacuation of the contents. At times the small amount of constitutional disturbances, slight degree of emaciation, good pulse, easy breathing, slight cough, and healthy complexion are in noticeable contrast with the physical signs. Cavities of the nature just described are mostly located in the base of the lungs. *Cavities due to bronchial dilatation.* Frequently for years the general health is almost unimpaired, and it is never so proportionately to the degree indicated by the physical signs. There is no hæmorrhage nor night sweats, and emaciation is not a pronounced symptom. The same physical signs persist for months or years unchanged, contrary to the history of most phthisical cavities, which continually alter with the advancing malady. The expectoration of bronchial dilatation is more abundant, fluid, and purulent than in catarrhal phthisis, and is usually brought up in the morning or evening by the cupful. It is not a constant spitting of nummular sputa, as in true consumption. In chronic cases the expectoration may become so fetid as to generate suspicions of gangrene; the cough is harassing, but is often relieved if the bronchial cavity is thoroughly emptied.

DR. MUSSER said that little could be added to this admirable and concise yet exhaustive résumé of Dr. Bruen on the morphology of phthisis. The limited experience that he had had in the study of the histology of phthisis had convinced him that in the microscopical structure of the lesions there is but little difference noteworthy in the primary changes. We have one school teaching that inflammation, another that tubercle, is the primary element. I cannot but agree with the author of the paper in the statement that the disease varies histologically with the variance in the intensity of one of these elements. In both we have epithelial proliferation and accumulation, changes in the vascular and lymphatic tissues (tubercle), and increase in the interlobular connective tissue. So intimately is the evolution of each of these processes connected that a classification like that of Greene [1] seems most proper. (A.) Consolidation, intra-alveolar. (B.) Consolidation involving mainly alveolar walls. (C.) Consolidation, consisting largely of intra-lobular connective tissue. Without absolute committal in either way, and yet in the line of exact truth, the distinction thus given seems to cover the entire histological ground.

Dr. Musser has had abundant opportunity for the study of the clinical aspect of phthisis, and although an arbitrary histological distinction of its varieties cannot be made, it is of the utmost importance as in fluencing treatment, and hence the prognosis of the case, to have a distinct and definite idea of the clinical varieties. The importance of the subject will be sufficient apology for the clinical remarks. Ante- and post-mortem observation has led him to adopt the following classification as convenient, systematic, and embodying the various phases of the disease: —

A. Acute. (1.) Catarrhal pneumonia.
(2.) Pneumonic or caseous phthisis.

[1] Lancet, 1882.

(3.) Pulmonary tuberculosis.
(4.) Miliary tuberculosis.

B. (1.) Catarrhal pneumonia, tubercle may be secondary.
(2.) Tuberculosis.
(3.) Interstitial or fibroid phthisis, tubercle may be secondary.

It is scarcely fair or proper to call acute catarrhal pneumonia a kind of phthisis, as it only is related as a possible primary factor. So seldom is it recognized and so baneful are the results of non-recognition, and hence inactive and inadequate treatment, that it is important to show its relation. It will be observed that catarrh and tubercle are distinguished, and so for *convenience* and *contrast* we may term the kinds "catarrhal" and "tubercular." Perhaps a clew to the pathology of phthisis may be found in defining the characteristics of each. In the first place there is a marked difference in the predisposing causes of the disease, — hereditary and diathetic condition. Thus tubercular phthisis is markedly hereditary, catarrhal is not; the tubercular is associated with the tubercular diathesis and a phthinoid chest, the catarrhal in some with the scrofulous diathesis and a perfect chest. Then the mode of onset differs greatly. In the former the general symptoms are more marked, the pulmonary symptoms in abeyance; in the latter the pulmonary symptoms are more marked, the general slight. Emaciation, loss of appetite, and dyspepsia precede or accompany the development of the former; they do not occur until late in the latter. Amenorrhœa and changes in the voice also occur early in tubercular phthisis. In tubercular phthisis hæmorrhage occurs more frequently and earlier than in catarrhal. In tubercular phthisis dyspnœa is a more marked and early symptom, and is out of proportion to the physical signs. Debility is more marked and more readily induced in tubercular phthisis. The temperature range is not so high early, and does not have the long daily sweeps in the late stages in tubercular as in catarrhal phthisis. With a doubtful mark it seems pleurisy, and chest pain is more common and constant in the tubercular than in the catarrhal form. The physical signs are bilateral and not pronounced in the tubercular form; they are unilateral and pronounced in the catarrhal form. The progress of the tubercular form is rapidly and progressively downward; of the catarrhal slow and in spurts. Tubercular phthisis is contagious (?) and auto-infective.

Over and over again do cases present themselves at the University Hospital and Dispensary with just such definite and broad distinctions, which distinctions should determine the line of treatment to be adopted, the catarrhal form requiring a more active local and general antiphlogistic treatment. It is not to be forgotten that the cases are not always, I may say generally, so easily distinguished, while the picture does not apply to acute miliary tuberculosis or fibroid phthisis. In a previous discussion on phthisis Dr. Musser had held that acute primary plastic pleurisy did not occur save in a tubercular subject, and hence was secondary to that diathesis. That statement is possibly too broad, and it should be that frequently recurring acute pleurisies occur only in the tubercularly diathetic, and are antecedent to the development of phthisis. The recognition of exocardial and subclavian murmurs, leads one to say that persons having such sounds are *threatened* with phthisis.

DR. ESKRIDGE said that he had been much interested in Dr. Bruen's remarks in most of which he con-

curred. As to pleurisy antedating phthisis, it was an old view which had lately been revived. He had been struck with the frequency of chest pains preceding phthisis, in over seven hundred cases of which he had notes; this symptom was noted in more than two-thirds. This pain may be on the opposite side to that of the affected lung. Interstitial phthisis is not always a chronic affection, Dr. Barlow and others having reported cases which proved fatal in six months. Hæmorrhage in his experience was a very common symptom in this variety of phthisis.

Dr. Eskridge called attention to the fact that cardiac valvular diseases, especially mitral regurgitations attended by venous congestions and coming on after birth, are rarely associated with phthisis, while congenital deformities of the heart attended by venous stasis, etc., are followed, according to some eminent authorities, in nine tenths of the cases, by tuberculosis of the lungs.

DR. SHAKESPEARE said that one point made by the lecturer had especially struck him as being opposed to his own experience, namely, that the earliest part of the lung attacked was generally the root. He had usually found the consolidation at the periphery of the lobe, often forming as it were a shell of solid lung, perhaps an inch thick, while the central or deep portions would be either not at all or but little affected. This peripheral consolidation seemed to have no particular relation to initial pleurisies, for the consolidations were quite frequently met with in cases almost free from pleurisy and old adhesions. He had also very often noticed at autopsies after death from intercurrent diseases wedge-shaped patches of solidified lung tissue having the base at the periphery of the organ, and a slightly raised surface much like infarcts, and containing miliary tubercles whilst the intervening pulmonary tissue was normal.

DR. FORMAD asked Dr. Bruen what he considered was the difference in the pathology of acute and chronic phthisis. Also on which side the disease most commonly occurred. Dr. Formad also desired to put on record some new observations on the histology of phthisis, made by W. H. Mercur in the pathological laboratory of the University of Pennsylvania, which he narrated as follows: That acute phthisis (all fatal cases) is invariably complicated with croupous pneumonia, which conditions the lethal termination; that the lining of the bronchioles and the endothelium of the blood-vessels plays a very active part in the formation of organized tubercle granulations, filling and widely distending the lumena in both instances. The existing observations on this point, as far as I remember, refer only to blood-vessels, and then merely to cheesy, broken-down material obliterating vessels, or occasionally to the formation of giant cells, or to something which in transverse section simulates a giant cell. Mr. Mercur states that the obliteration of bronchioles by living, organized granulation tissue is the most common starting-point for pulmonary tubercle granulations, and forms the greater bulk of the latter. He also found that the exudate within the air vesicles in acute phthisis was capable of undergoing complete organization, and that a group of such blocked-up air vesicles with organized exudate is usually called (erroneously) a miliary tubercle, the outlines of the air vesicles being mistaken for submiliary tubercles. Mr. Mercur had failed to find a single true miliary tubercle in a large number of thoroughly studied cases of phthisis, and agrees with those who regard miliary tubercle nodes as secondary products only. Dr. Formad desired distinctly to state that Mr. Mercur's observations were made on, and apply only to, the lungs.

DR. TYSON was interested to note how much histological investigation has contributed to our knowledge of the nature of these important processes under discussion; and while he was ready to admit that we owe much to experimental pathology, he felt that our present more correct notions were the result of microscopic studies of the human tubercular lung. The point to be insisted upon is that all these processes are tubercular and all are inflammatory, the catarrh of the lung and tubercle granulations being in all cases the initial lesion, whence it extends peripherally by desquamative catarrhal pneumonia or centripetally by a tuberculous peribronchitis, the former furnishing the rapid and the latter the slow forms of phthisis. That pleurisy is often the initial lesion of tuberculosis he thought had long been acknowledged.

DR. SHAKESPEARE said that the observations reported by Dr. Formad for his pupil reflected great credit upon both, and was another testimony of the value of the work done in the pathological laboratory of the university, but at least two of the announcements, for which novelty and originality were claimed, had been forestalled years ago by other observers. He had particular reference to the organization of the products within the alveoli of the lung, and the announcement that the walls of the minute blood-vessels by a proliferating endarteritis and periarteritis formed the miliary tubercle. The former is not only recognized and described in Green's Handbook of Pathology, but is most beautifully *illustrated*. The latter has been repeatedly observed and published, sometimes with illustrations. This origin of tubercle is distinctly referred to in the text-books of Wagner, and Cornil and Ranvier. All these books are in the hands of the university students.

DR. FORMAD said that existing observations on this point, as far as he remembered, referred only to blood-vessels, and then merely to cheesy, broken-down material obliterating the vessels, or occasionally to the formation of a giant cell, or to something which in transverse section simulates a giant cell.

In closing the debate upon the subject DR. BRUEN said that he coincided with Dr. Tyson in the opinion that phthisis was rarely associated with heart disease. In mitral regurgitation there was often indeed a thickening of the pulmonary substance allied to the indurative changes in the other organs from like causes. Advanced fibroid disease with cavities, as shown in one of the specimens exhibited by him through the kindness of Dr. Hinsdale, he had not met with heretofore. Dr. Formad's query as to the relative frequency of phthisis upon the right or left side he felt must be answered by the statement that one side was as liable to disease as the other, while, probably, in a small majority the right side was most frequently involved. He thought that the peripheral portions of the apices anteriorly was the most common starting-point, where there was much desquamative pneumonia and rapid phthisis, while the roots posteriorly were primarily attacked in the more slowly developed forms of broncho-pneumonic phthisis. The roots of the lungs are the seats of the latent phthisis developed as the sequential lesion of croupous pneumonia. Dr. Bruen dissented from the view that croupous pneumonia was a

frequent cause of death in phthisis. He believed that in the rapid, as well as in the more latent, form of phthisis, death was preceded and hastened by a development of the tubercular nodular tissue to which allusion had been already made. This tissue completely fills up and chokes the acinous pulmonary structure, causing dyspnœa, etc.

Recent Literature.

Compend of Anatomy; for Use in the Dissecting Room and in preparing for Examinations. By John B. Roberts, M. D. Third edition. Philadelphia: C. C. Roberts & Co. 1882.

If we remember rightly, we spoke rather kindly of this little work when noticing a former edition, and, indeed, compared with other works of the same class, it is deserving of some praise. We must say, however, that we look on the success of similar books as very detrimental to the knowledge of anatomy. The purpose for which they are bought is to enable the student to pass examinations with as little trouble, and, consequently, real knowledge, as may be. It is not certain that in all respects this book is good enough to much facilitate this devoutly to-be-wished consummation. Let us take one or two examples almost at random. "The fingers are each supplied by two arteries on the dorsal and two on the palmar surface, which come from the arches, or from the interosseous branches." It is stated that Peyer's patches may be circular or oval, which is true, but in point of fact they are nearly all oval. The internal cutaneous nerve is omitted from a kind of a diagrammatic description of the brachial plexus apparently because it would interfere with its symmetry. Books of this kind will be written as long as there is a demand for them. The remedy is in the hands of examiners, who should endeavor to frame questions demanding real knowledge to answer.

Experimental Pharmacology. A Handbook of the Methods for Studying the Physiological Action of Drugs. By L. Hermann. Translated, with the author's permission, with notes and additions, by Robert Meade Smith, M. D. Philadelphia: H. C. Lea's Son & Co. 1883. 12mo. 201 pages.

This little book deserves a warm welcome, as it draws attention to a department of applied physiology by far too much neglected in American medical schools. The original appeared in 1874, but the translator has added much which will help to bring the book up to the level of the present. Thirty-two illustrations have been introduced, too few or too many according to the reader's familiarity with physiological technics. A description of isolated electrodes is, unfortunately, wanting.

The chemical side of the subject is rather slighted; for example, the determination of the oxygen consumption and carbonic acid production is too lightly passed over, this being a matter on which the tyro needs very particular instruction. The section on ozone (page 30) will hardly meet with general approval. The measurement of temperatures has also become too important to receive so little attention, and deserves a long note. There have been many recent observations which point out the Scylla and Charybdis of thermographers, particularly when busied with rabbits and guinea-pigs. Good methods of producing fever for pharmacological study might also have been included among the additions. The new way of working with crushed tissues whose cells still live ["Organbrei," organ pulp (?): Bunge, Schmiedeberg, W. Kochs, Binz, Seegen] is of so much promise that an explanation could have been given with advantage.

The translation is good; the appearance of the book excellent. The proof has been usually carefully read. There is a good index. May a new edition be called for soon, and the editor then feel inclined to add a chapter on the literature and one on the best way to use the more common drugs which have an interest in this connection. J. W. W.

Transactions of the Medical Society of the State of Pennsylvania at its Thirty-Third Annual Session, held at Titusville, May 10, 11, and 12, 1882. Published by the Society. Philadelphia. 1882.

This volume of 450 pages affords a most satisfactory example of what may be accomplished by a State medical society in the line of its proper and legitimate functions. A large portion of the book is occupied with valuable original papers on professional topics, and there is also much collateral information of interest to physicians, as for instance a list of all the medical schools represented by practitioners in the State, which may be taken as a tolerably complete list of the medical schools of the country. Most of the leading schools of Europe also are represented by one or more graduates. The number of registered practitioners is 6492.

— The February number of the *American Journal of Obstetrics* gives great prominence to the advisability of immediate removal of the secundines after abortion, contrary to the teaching of many of the treatises on midwifery and the practice of many of the older men in the profession. The most striking of the articles in our contemporary is that of Dr. Mundé, which is accompanied by a list of fifty-seven cases in which the placenta was removed by the writer with only one death, and that from septicæmia which had developed before the operation. The symptoms calling for the removal were in eight cases exhausting hæmorrhages, and in five present septicæmia; yet of the total fifty-five made an uninterrupted recovery. The method of removal was in twenty-two manual, and in thirty-one instrumental (curette and forceps). Ergot was used in the remaining four cases.

— Americans are credited in England with the discovery of a new panacea. It has the advantage of simplicity, for it consists of half a glass of very hot water, taken morning and evening, or whenever a "pick-me-up" is required. It is said to cure gout, rheumatism, indigestion, dyspepsia, and many other of the complaints to which flesh is heir. It appears that it has been tried with good effect by a considerable number of people in England, and notably by those whose brains are heavily taxed.

Medical and Surgical Journal.

THURSDAY, MARCH 8, 1883.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the under signed, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

FREE TRADE IN DIPLOMAS.

WE have no desire to weary our readers with too frequent reference to the establishment, under the laws of Massachusetts, of so-called medical schools, with the power to grant degrees without limit or restriction. The condition of affairs is so startling that it merits earnest consideration, and at the risk of seeming wearisome we propose to refer again to some of the curious conditions which result from the existing law, with the hope that our importunity may weary our officials into the execution of statutes whose present working proves anything but salutary, or if the laws are insufficient, induce our legislators to amend them.

The law in question was evidently framed with the intention of giving protection in the simplest way and at the least trouble and expense to persons desiring to associate themselves together for manufacturing, charitable, and other purposes, and doubtless it serves its object.

But the very simplicity of the required proceedings opens the door to fraud. Sufficient guarantees of honesty and good intentions are not required, and the State too easily gives its sanction to it knows not what. In most matters this laxity of the law can work no harm. It is useless to seek its protection to form a corporation for the transaction of any nefarious business, for no incorporation under general laws could save the perpetrators from punishment under other laws which control such matters. Institutions incorporated under this law, ostensibly for educational purposes, really for the sale of diplomas, have shown little power to do harm outside of medicine. Other degrees than that of Doctor of Medicine may be and perhaps are sold, but they are subject to somewhat different conditions. The degrees given for knowledge not professional have, we suppose, for reasons hardly necessary to enumerate, little, if any, market value. An institution which attempts to sell degrees in law or divinity would find a very small market for their wares, for other tests than the mere possession of a diploma are employed in these two professions. A medical diploma, however, is useful in impressing the ignorant, who are unable to distinguish as to its value or genuineness; and in by far the greater number of these United States a man may make any claim for himself, may arrogate to himself any powers derived from heaven or hell, may do almost anything he pleases, short of violent murder, without let or hindrance, provided only he style himself a practitioner of medicine.

The law to which we have referred simply provides that seven or more persons desiring to become incorporated, shall meet and choose officers, fill out certain printed forms, and pay a fee of five dollars. The general character of the act is shown by its Second Section: —

"SECTION 2. Such a corporation may be formed for any educational, charitable, benevolent, or religious purpose, for the prosecution of any antiquarian, historical, literary, scientific, medical, artistic, monumental, or musical purpose, for promoting temperance or morality in the Commonwealth; for supporting any missionary enterprise having for its object the dissemination of religion or educational instruction in foreign countries; for encouraging athletic exercises or yachting; for encouraging the raising of choice breeds of domestic animals and poultry; for the association and accommodation of societies of Free Masons, Odd Fellows, Knights of Pythias, and other charitable or social bodies of a like character and purpose; for the establishment and maintenance of places for reading rooms, libraries, and social meetings."

If the formation of a medical school is the object of the association it is not necessary under this law that any of these individuals should have any knowledge of medicine, or that the corporation should possess one dollar of capital; and according to a recent decision quoted in these pages there is not the slightest limit to the issue of diplomas. It is not necessary that the recipient should ever have been seen by any member of the corporation or its supposed instructors. Indeed, if such an interpretation of the law is to stand, we can see no reason why diplomas should not be given like chromos to every purchaser of a paltry vial of any nostrum one of these diploma-making corporations chooses to stamp with the seal of its approval.

It was believed at the time we called attention to the subject and the ruling of the United States Commissioner that that official's view of the matter was shared by the legal authorities of the State. The Attorney General was present during the delivery of that opinion, and it was believed that he acquiesced in it, as the prisoner — the representative of the Bellevue Medical College — was discharged, and no farther action taken in the premises. We are glad to know, however, that a different opinion now prevails. In reply to a note from the State Board of Health, Lunacy, and Charity, asking the opinion of the present Attorney General in regard to the right of institutions incorporated under the general law to confer degrees, an answer, signed by the Assistant Attorney General, was given, of which the conclusion is as follows: —

"A degree carries with it a certain mark and distinction, and in the case of colleges the Legislature has given expressly the right to grant degrees, and in the case of other educational institutions has as expressly omitted to give it. This distinction cannot be accidental, and it is clear the Legislature did not consider the power to grant degrees as one of the ordinary powers necessary and proper for all educational institutions, but a special power, privilege, and franchise, which the Legislature has from the beginning carefully

guarded and shielded from abuse, and which it still keeps under its control and care, never granting it by implication, but by an express act.

"The general law does not confer the right to grant degrees."

This matter has no connection with the regulation of the practice of medicine. In regard to the propriety and feasibility of such regulation we know there are wide differences of opinion in the community and in the profession itself. No man, whatever his views in regard to the practice of physic, who has any regard for common honesty, can approve of the fraudulent sale of diplomas, and whatever may be right in this matter in the eyes of the law it is certainly a fraud *de facto*, if not *de jure*, to certify that a man, entirely unknown to the certifier, is learned in medicine, when the only evidence he offers is the payment of a paltry fee. An honest degree has no legal status, so far as we know; its possession carries with it no privilege in this State that we are aware of, but that does not make the issuing of dishonest ones less dishonorable, and in the name of common honesty, and we trust none of our readers are so skeptical as to inquire, —

"In what age hath honesty been common?"

we hope the fraudulent production may be deprived of even the shadow of encouragement by the State of Massachusetts.

WHAT MAY REASONABLY BE EXPECTED FROM MORE INSTRUCTION IN MENTAL DISEASES.

A committee of the National Association for the Protection of the Insane and the Prevention of Insanity has been delegated by the council of the Association to call the attention of the medical faculties in this country to the need which medical students have of more instruction, didactic and clinical, in mental diseases, on the grounds that the incipient stage of mental disease must always be passed under the observation of the general practitioner (which is by no means true); that usually the diagnosis of insanity is incorrectly or imperfectly stated in medical certificates; that a rational attempt to treat the case at home is not made, because the physician shrinks from assuming a responsibility for which he has never been prepared; that medico-legal cases are often complicated and rendered obscure by the ignorance of the physicians who are called to testify in regard to them, and that many cases of impending insanity are allowed to progress when an adequate knowledge of the subject might have enabled the family physician to ward off the catastrophe. The committee (composed of Drs. E. C. Seguin, M. Putnam Jacobi, and Margaret A. Cleaves) expresses the opinion that a training in psychiatry would enable the general practitioner to more successfully treat the mental symptoms exhibited by many patients not actually insane; that the time has come when in this country no course of medicine should be considered complete without attendance upon lectures and clinics on mental diseases; and that no student should be allowed to graduate without passing an examination in psychiatry. The different medical schools are urged, in a circular the language of which we have used quite nearly, to provide such instruction by means of a chair or lectureship in psychiatry and a clinic of psychiatry, held in an asylum for the insane, provided they have not already done so.

The purpose of the Association is certainly a most excellent one, and the results which it wishes to bring about are most praiseworthy. But it evidently expects too much, both in the prevention and cure of insanity, from the means which it proposes. Of mental disease, perhaps more than of any other, is the remark Dr. Holmes true, namely: "There are people who think that everything may be done if the doer, be he educator or physician, be only called in season. No doubt; but *in season* would often be a hundred or two years [perhaps not quite so much as that] before the child was born, and people never send so early as that." It is one of the mysteries of Providence, too, that parents who transmit to their children a bad mental organization are allowed to destroy what little chance they have in life by giving them a vicious training. Let us by all means have a society with a long name to regulate matrimony.

With regard to the complication of medico-legal testimony by ignorant experts, there will always be enough of that class, and it is precisely they by whom lawyers can often make their points best, so that they are not likely to fail of employment as long as our present laws stand. The proper certifying and committing of the insane to asylums will be advanced by better medical education, but a competent lunacy commission is quite necessary to that end.

THE BACILLUS TUBERCULOSIS AND THE CONTAGIOUSNESS OF PHTHISIS.

In a paper on tuberculosis, read lately before the New York County Medical Society, Dr. Heitzman expressed considerable doubt as to the infectiousness of the disease, as claimed by Koch and his followers especially since the discovery of the *bacillus tuberculosis*. It was a problem yet to be solved, the reader said, whether bacilli were the cause or merely a product of tuberculosis. In regard to the experiments on animals, he remarked that the German investigators found that rabbits and guinea-pigs developed tuberculosis after the insertion of bits of wood, glass, aniline dye, and other substances under the skin, and that simple injuries sometimes resulted in the production of the disease. It seemed probable that these animals after long confinement, especially in laboratories, were particularly predisposed to tuberculosis.

On the invitation of the president, Dr. Belfield, of Chicago, made a reply to the paper, in which he reminded Dr. Heitzman that the very investigators whom he had cited as having proved by their experiments that the rabbit and the guinea-pig inoculated with almost any extraneous substance would develop tubercu-

losis had afterwards acknowledged that those experiments which were successful in accomplishing this result had been conducted exclusively in laboratories where tuberculous matter had been in almost constant use for long periods of time in the prosecution of other researches. It seemed probable, therefore, that the wood, glass, aniline, or other substance used had in reality become infected by the tuberculous matter, for when the same experiments were repeated by the same individuals outside of the laboratory tuberculosis failed to develop. It was owing to these later experiments that one of the physicians referred to finally adopted the theory of the infectious nature of tuberculosis. Furthermore, Koch had shown that animals, such as the cat, dog, and rat, which were not naturally predisposed to tuberculosis, had almost invariably developed the disease when inoculated with tuberculous matter. The experiments of various observers showed it to be true that different individuals of the same species were more disposed than others, by reason of physical condition, to the same disease. Tuberculosis seemed to occur spontaneously in some instances, but so also did diseases which were distinctly recognized as infectious, like pyæmia, for example. Many physicians were known to have contracted this disease through abrasions on the hands by contact with pyæmic patients, while others, with simple injuries, developed pyæmia without any apparent contact whatever with pyæmic poison. It was undoubtedly true, however, that the specific pyæmic poison was present in every instance, and he held that tuberculosis presented a parallel case. Whether bacilli were the cause or a product of tuberculosis, he said in conclusion, would not be accepted as settled by the medical world until more extended experiments in the future had disproved or confirmed Koch's views.

REPORT OF THE COMMISSION TO INVESTIGATE THE WATER SUPPLY OF BOSTON.

COMMISSIONS have been simultaneously investigating the water supplies of Boston and New York, and at the same time the condition of the supply of Philadelphia caused the introduction of a bill into the Legislature of Pennsylvania to secure a commission, in the absence of a State board of health, to regulate the pollution of streams.

The difficulty in New York was in regard to the quantity of the supply, in Philadelphia it was the quality, in Boston both quantity and quality were to occupy the attention of its Commission. With the growth of our large cities and an increasing density of the population of surrounding districts certain common difficulties will present themselves for solution touching their water supplies, and certain legislative action will be required from their respective State governments. Insufficiency and impurity of the water supply are the two difficulties which all our larger cities are sure, sooner or later, to encounter under existing conditions. Insufficiency may be avoided by either a still more lavish supply or by a less wasteful use of water. Impurity may be guarded against to a great extent by the proper construction of storage basins, and by such legislation and execution of laws as will prevent or reduce to a minimum the pollution of streams which are sources of water supply by sewage or the refuse of manufactories.

Neither the origin of the troubles nor the remedies to be supplied are so far to seek or so difficult to apply, were it not for conflicting interests which confuse and obstruct any efforts in these directions.

In New York the Commission has reported that an increased supply of water is required, the president of the Board of Health taking the ground that a charge according to the quantity consumed, or the use of water meters, would result in a restriction of the amount used by the poor.

The Boston commissioners report that measures should be taken at once to reduce the consumption. As this averages at present one hundred gallons daily for each inhabitant, and fifty or sixty gallons is usually considered a very liberal allowance, there seems to be no reason why even the poor should question the wisdom of the commissioners. Moreover, a charge need only be placed on water used in excess of a certain fixed amount.

The report of the Boston commissioners forms a document of nearly two hundred pages, the report proper occupying seven pages, and the testimony the rest of the space. The report itself is signed by all the members of the Commission, and some concessions of individual views must have been necessary to reach such a result. The Cochituate and Sudbury supplies only were investigated. The Commission availed itself of the best testimony to be had, and the report is evidently based on the best part of that testimony, which is equivalent to saying that it is a plain, sensible, straightforward paper, such as the citizens of Boston desired and had a right to expect.

The recommendations in regard to the Sudbury River supply are thus summed up: "(1.) A conduit should be built across Farm Pond. (2.) The aqueduct to Boston should be thoroughly cleaned each year. (3.) The basins should be deepened around the edges, no shallow flowage of less than eight feet tolerated, and all loam should be removed from this part of the bottom. If this were done its effects upon the water might be tried for a year before commencing the much greater business of removing the large accumulations from the centre of the basins. (4.) Measures should be taken at once to reduce the consumption. With these precautions the Commission have no hesitation in saying that they believe the Sudbury River can be made a sufficiently healthy and satisfactory supply, although it will probably always retain a slight color as compared with the Cochituate."

The following are the recommendations in regard to the Cochituate supply: "First, to abandon all shallow flowage where the water is less than eight feet deep, and remove what loam there may be in water of that depth. Second, to thoroughly cleanse the Cochituate aqueduct every year to insure the removal of the sponge. Third, to prosecute without delay the people now polluting our supply, or else, if in the

opinion of counsel the present statutes are insufficient, to seek legislative relief."

The above recommendations exhibit the sources of existing difficulties in the supply of water, and suggest, we believe, the most promising remedies in so far as difficulties or remedies are at present understood, and this is all that reasonable citizens can demand from this Commission.

Incidentally it is recommended that periodic scientific examinations of the water, extending over a term of years, should be made. These should be both of a chemical and biological character, and might furnish data from which interesting and perhaps valuable conclusions could be drawn.

Chemistry seems to have done nearly as much for us already as can be anticipated from it in this direction, and it would be rather to the labors of the mycologist that we should look for new results. An entirely suitable person for conducting such work is not easily found.

Chemistry may tell us when there is danger, but it cannot assure us of safety. The recently attempted application of Koch's method of cultivation of organic germs in gelatine to the physiological and organic testing of polluted waters offers some hopes of reaching positive results. At present we can only say positively from experience that micro-organisms such as those supposed to represent the causative poison of typhoid fever, for instance, are robbed of their activity neither by filtration through extensive banks of earth nor by dilution in very large bodies of water.

Incidentally, again, the inquiries of this Commission suggest the importance of some system of metropolitan sewerage for Boston and its surrounding towns. The laws on the statute books to prevent the pollution of streams which are sources of water supply may be in themselves sufficient, — just as we are now told by her Attorney-General that the Massachusetts laws are sufficient to prevent indiscriminate trade in diplomas, — but the execution of such laws is attended with much friction here as elsewhere, where a dense manufacturing population is found with its many vested interests, and where no other resource presents itself for the disposal of sewage.

The *Westminster Review* for October, 1882, contains an article on River Pollution in England, which our readers who are interested in the subject might refer to with profit.

We are glad to compliment the commissioners on their recommendations, and hope before very long to be able to record their conscientious and successful application.

MEDICAL NOTES.

— Professor Simpson, in his address on the history of the chair of midwifery at the University of Edinburgh, says much that is interesting about the popular prejudice against "men-midwives" in Great Britain two centuries ago. So furious was the opposition to what was considered an immodest innovation that it was not safe for a medical man to be known as an accoucheur. The following quotation from Dr. Aveling's *History of English Midwives* illustrates the popular sentiment. Dr. Willughby, whose daughter was an expert midwife, says: "In Middlesex, anno 1685, my daughter, with my assistance, delivered Sir Tennebs Evank's lady of a living daughter. All the morning my daughter was much troubled, and told me that shee feared that ye birth would come by ye buttocks. About seven o'clock that night labour approached. At my daughter's request, unknown to the lady, I crept into the chamber upon my hands and knees, and returned, and it was not perceived by ye lady. My daughter followed me, and I being deceived through hast to go away, said that it was ye head, but she affirmed the contrary; however, if it should prove ye buttocks, that shee knew how to deliver her. Her husband's great Oliverian power, with some rash expressions that he uttered, flowing too unhandsomely from his mouth, dismayed my daughter. She could not be quieted until I crept privately again the second time into ye chamber, and then I found her words true. I willed her to bring down a foot, the which shee soon did, but being much disquieted with fear of ensuing danger, shee prayed mee to carry on the rest of the work."

— The California Assembly has passed a bill to meet the plea of insanity in cases of murder. The indicted man who pleads it is to be first examined as to his sanity without regard to the crime charged. If decreed to be sane he is tried for murder, and his false plea is to be treated as an aggravation of the offense. If shown to be insane he goes to an insane asylum at once for life, so that he shall never harm anybody else. If however, any evidence turns up afterward to prove that the decision was wrong, then he is to be taken and tried for murder on the original charge.

— Governor Stephens, of Georgia, makes the remarkable proposition to place in the National Statuary Gallery at Washington the statue of Dr. Long, of Athens, Georgia, who was, says Governor Stephens, "two years ahead of Wells and Morton in his application of sulphuric ether for the relief of pain in surgical operations, and to whom, therefore, belongs the honor and glory of this greatest discovery of modern times." Dr. Long's claims as a discoverer were strongly advocated by Dr. J. Marion Sims some years since.

— Who will depreciate the value, even pecuniary, of pathological researches? A modest physician in Paterson, N. J., has presented the following bill to that city: "To breaking up the ravages of diphtheria by showing it to consist of a few ounces of foreign matter in the blood, which can only escape through the pores, $1500; to lowering the death rate of the city to the extent of 538 lives in two years by means of circulars, letters, cards, and tracts, showing what fever consists of, $2000; to stopping ravages of smallpox by showing that 100 cases of it can be expelled from the blood by the vigorous action of the pores, produced by hot tea, $1500. Total, $5000."

— The officers of the medical corps of the United States Navy, in order to establish more intimate social

and friendly relations among its members, to furnish occasions for the interchange of professional experiences, and to assist each other in scientific inquiry and research, have agreed to form an association, to be entitled The Naval Medical Society, in which every officer of the medical corps shall have the right of membership upon notifying the secretary that such is his desire. The Society is to hold regular and stated meetings on the first Thursday of every month, in the city of Washington, and at such other times as the business committee may consider advisable, or when five other members may so request. At the annual meeting, held January 4, 1883, the following officers of the Society for the current year were elected: President, Albert L. Gihon, M. D.; Vice-President, John M. Browne, M. D.; Secretary, James M. Flint, M. D.; Business Committee, Thomas J. Turner, M. D., Adolph A. Hoehling, M. D., Thomas H. Streets, M. D.

— Dr. Snow, city registrar, says that a census of Providence, taken in the month of January by men of experience and responsibility, shows a total population of 116,755, of whom 55,736 were males, and 61,019 were females. The gain in population since the United States census of 1880 is 11,898, or 11.34 per cent., an average of 4.53 per cent. annually.

NEW YORK.

— At the meeting of the Academy of Medecine held March 1st, Dr. Isaac E. Taylor read a paper on The Naturally Faulty or Contracted Pelvis, with the History of a Case of Labor, the non-delivery of the child, and the death of the mother, after craniotomy and cephalotripsy.

— The annual commencement exercises of the Buffalo Medical College were held February 27th, when a class of fifty-six graduates received diplomas.

— The commencement of the American Veterinary College was held at Chickering Hall, February 28th. Prof. Charles A. Doremus awarded a number of prizes, and the valedictory address was delivered by Samuel K. Johnson, after which the Rev. Henry Ward Beecher made the address to the graduating class, which numbered twenty-two.

Miscellany.

HOW THEY MAKE "COD-OIL" AT SWAMPSCOTT.

THE *Edinburgh Medical Journal*, February, 1883, thus describes one of the important though unsavory interests of a neighboring watering-place: Swampscott is a little town upon the coast of Massachusetts, not far from Lynn, situated near the head of a bay between Nahant and Salem. Off this ancient haunt of fishermen, at a distance of about nine miles, is a place called the "rocks," where, in the winter, the codfish come in shoals to spawn, and the striped bass sport themselves in the summer. During the winter months, be the weather what it may, unless the wind be rising for a gale, a little after midnight men may be seen going about the village, stopping here and there at houses, rousing the fishermen, who by and by gather in groups about the shore, each with his "dory," that well-known model of Yankee ingenuity which at the great Berlin fishery exhibition excited so much attention. The dories and their owners are soon aboard the various schooners in waiting, and by five A. M. the fleet is at the "rocks;" so, when the daylight is sufficient, the dories anchor about their respective larger crafts, each boat with its single occupant, who is soon hard at work robbing the sea of its life. About three P. M. the signal is given from the schooners to come aboard; the dories hasten to their floating castles, with pitchforks the various "catches" are soon thrown aboard, and sail is made for home. During the passage the fish are gutted, the entrails cast into the sea, and the livers, some of them large enough to fill a quart mug, are put into baskets. When the shore is close at hand, the fish are put again into the dories; but the roughness of the sea usually is such that these boats, when loaded, cannot land, and into the icy sea-water the horses are driven until the carts reach such a place that the codfish can be put in them, when off they go, to plod the night through for the early Boston market. The livers are immediately sorted over and the gall-bladders carefully removed. The great, luscious, flabby masses are thrown into a large oak tub; with this are connected steam pipes. When the receptacle is full and closed, low-pressure steam is turned on, and for about two hours and a half cooking goes on. Then the plugs are taken out at the bottom, and the hot oil streams into buckets. It is now placed in butts in the "cooling room," and allowed to stay there until it freezes solid. So it is kept till opportunity offers, when it is put in canvas bags holding about four gallons each. These bags are then placed regularly upon a heavy oak table provided with outer grooves for conducting liquid, until twelve gallons are in a row. On this is laid a slab, then canvas bags, and so layer after layer, until about eighty gallons are piled up. A ton of pig-iron is then placed upon the top slab of oak, and the oil begins to flow out. In about twelve hours dripping ceases, and the apparatus is taken apart. Inside of the bags is found a yellowish, butter-like mass as hard as tallow, which is nearly pure stearin, with liver débris and fibres. This goes to the soap-makers, whilst the oil finds its way to the Massachusetts General Hospital and other places where the superiority of the finest American oil over the Norwegian is recognized.

A LOW TEMPERATURE.

A CORRESPONDENT of the *Medical Record* reports a case of subnormal temperature, which, if correctly observed, upsets the common teaching of physiology: —

"An intoxicated man spent the night of December 18th in an open coal shed. He had the protection only of ordinary clothing, and when found, late the next forenoon, was apparently dead. Closer inspection revealed signs of life, and after six hours our efforts to restore him were successful. His temperature was taken about four hours after he was found. The thermometer was a verified, self-registering one, graduated from 90° F. upward. The register could, however, be shaken down for a space equal to 5° more. It was so fixed and placed in the rectum, where it remained for seven minutes. The register was not lifted at all. The patient's temperature, therefore, did not exceed 85° F. We cannot say how much lower it was. Shortly after consciousness was regained the axillary temperature was 100.2° F."

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 24, 1883.

[1] Including sixteen children killed during panic in school.

Deaths reported 2796 (no report from Milwaukee): under five years of age 927: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 531, consumption 457, lung diseases 444, diphtheria and croup 165, scarlet fever 85, small-pox 73, typhoid fever 42, diarrhœal diseases 38, whooping-cough 31, cerebro-spinal meningitis 24, malarial fever 20, measles 19, erysipelas 18, puerperal fever 16. From *typhoid fever*, Philadelphia nine, Chicago seven, Pittsburg six, New York and St. Louis five each, Brooklyn, Boston, Cincinnati, District of Columbia, Providence, New Haven, Worcester, Holyoke, Milford, and Southbridge one each. From *diarrhœal diseases*, New York 18, Brooklyn and St. Louis three each, Chicago, Cincinnati, Pittsburg, and Buffalo two each, Philadelphia, Baltimore, New Orleans, Providence, Lowell, and Cambridge one each. From *whooping-cough*, New York 13, Brooklyn six, Pittsburg four, Cincinnati and Buffalo two each, Philadelphia, Chicago, Baltimore, and New Haven one each. From *cerebro-spinal meningitis*, New York and Chicago five each, Fall River four, Philadelphia and New Orleans two each, Boston, Pittsburg, Lowell, Worcester, Fitchburg, and Quincy one each. From *malarial fevers*, New York seven, Brooklyn four, St. Louis three, Philadelphia and New Orleans two each, Chicago and Springfield one each. From *measles*, New York 12, Cincinnati two, Boston, Baltimore, New Haven, Holyoke, and Hyde Park one each. From *erysipelas*, Philadelphia four, Brooklyn and Boston three each, New York and Cincinnati two each, Chicago, Providence, and New Haven one each. From *puerperal fever*, Brooklyn four, New York, and Chicago three each, Boston two, Philadelphia, St. Louis, Cincinnati, and Cambridge one each.

Eighty-five cases of small-pox were reported in Baltimore, Pittsburg ten, Brooklyn two, Buffalo two; diphtheria 40, scarlet fever 24, and typhoid fever four, in Boston.

In 41 cities and towns of Massachusetts, with an estimated population of 1,186,411 (estimated population of the State 1,922,530), the total death-rate for the week was 19.94 against 16.09 and 21.25, for the previous two weeks.

In the 28 towns of England and Wales, with an estimated population of 8,620,975, for the week ending February 10th, the death-rate was 23.5. Deaths reported 3882: acute diseases of the respiratory organs (London) 390, whooping-cough 116, scarlet fever 80, fever 76, measles 46, diarrhœa 33, diphtheria 25, small-pox (Newcastle four, London two, Sheffield one) seven. The death-rates ranged from 13.4 in Derby to 33.3 in Liverpool; Cardiff 16.2; Brighton 20.2; London 21.5; Nottingham 22.2; Birmingham 23.9; Portsmouth 25; Sheffield 26.7; Manchester 27.1. In Edinburgh 26.8; Glasgow 30.6; Dublin 37.9.

For the week ending January 27th, in 169 German cities and towns, with an estimated population of 8,356,524, the death-rate was 26.5. Deaths reported 4265: under five years of age 1859; consumption 629, lung diseases 523, diphtheria and croup 190, scarlet fever 80, whooping-cough 74, typhoid fever 49, measles and rötheln 36, puerperal fever 14, typhus fever (Breslau, Posen, and Braunschweig one each) three, small-pox (Heilbronn one) one. The death-rates ranged from 15.3 in Metz to 35.9 in Dortmund; Königsberg 29.1; Breslau 31.1; Munich 32.2; Dresden 23.6; Berlin 23.7; Leipzig 23.7; Hamburg 30.7; Cologne 22.3; Frankfort 23.8; Darmstadt 20.6.

For the week ending February 10th, in the Swiss towns, population 494,390, there were 46 deaths from consumption, lung diseases 46, diphtheria and croup 15, diarrhœal diseases 14, scarlet fever four, typhoid fever two. The death-rates were, at Geneva 23.6; Zurich 22; Basle 25.4; Berne 28.2.

The meteorological record for the week ending February 24th in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

LINES WRITTEN UPON AN INFANT'S FIRST BIRTHDAY.

BY L'ACCOUCHEUR.

INCARNATE dream of that which is to be;
Stupendous history of what has been:
The unknown past and future meet in thee.
Who shall record thy destiny, — and when?

There lives no poet who thy fame can sing,
Thou shalt have judgment only from thy peers.
Perhaps thy life with joy and praise shall ring,
Perhaps be passed in silence and in tears.

What shall thy mission be? wert thou forewarned?
Say, wert thou welcome, or didst thou arrive
Unwished for, hated, till thy birthday dawned?
Such is the fate of some. Since thou art here,

Oh! plead with mothers that they do not kill
The unborn infants Nature bids them bear.
Bid love and life their mutual course fulfill;
Bid life and love their mutual burdens share.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 23, 1883, TO MARCH 2, 1883.

BURTON, HENRY G., captain and assistant surgeon. The leave of absence granted October 2, 1882, is extended two months. Paragraph 2, S. O. 49, A. G. O., February 28, 1883.

FESSON, LOUIS S., captain and assistant surgeon. To be relieved from duty at Fort Clark, Texas, and assigned to duty at Fort Ringgold, Texas, as post surgeon. Paragraph 5, S. O. 20, Department of Texas, February 21, 1883.

SUFFOLK DISTRICT MEDICAL SOCIETY. THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE will meet at 19 Boylston Place, on Wednesday March 14th, at **7.45** o'clock. Dr. M. H. Richardson will report A Case of Empyæma. Dr. F. Minot will open the discussion. Dr. C. P. Putnam will present a paper upon Diphtheria. Drs. F. I. Knight and J. Collins Warren will open the discussion.

ALBERT N. BLODGETT, *Secretary.*

RHODE ISLAND MEDICAL SOCIETY. — A regular quarterly meeting of the Society will be held in Lyceum Hall, 62 Westminster Street, Providence, on Thursday, March 15, 1883, at ten A. M. Papers as follows: Dr. G. T. Swarts, Recent Statistics of Typhoid Fever in Providence; Dr. S. S. Keene, Treatment of Pneumonia; Dr. E. M. Snow, Early History of Vaccination in Providence. G. D. HERSEY, *Secretary.*

CORRECTION. — Mr. A. B. Haggett, reported by mistake in the last issue of the JOURNAL as succeeding Mr. G. P. Carter on the Massachusetts Board of Health, Lunacy, and Charity, really succeeds Hon. Ezra Parmenter, deceased.

BOOKS AND PAMPHLETS RECEIVED. — The Pharmacopœia of the United States of America. Sixth Decennial Revision. By authority of the National Convention for Revising the Pharmacopœia, held at Washington A. D. 1880. New York: William Wood & Company. 1882.

TWO CASES OF REMOVAL OF IMMENSE FATTY TUMORS BY ABDOMINAL SECTION.[1]

BY JOHN HOMANS, M. D.,

Surgeon to the Massachusetts General Hospital.

I AM not acquainted with any reports of the removal of fatty tumors from within the abdominal cavity approaching in size those to be described in this paper. Plaster casts of two of them taken by Dr. Whitney, curator of the Warren Museum, have been kindly lent me, and are on the table before you. As I have met with these two, probably other operators of greater experience have met with more. Mr. Cooper Forster showed at the Pathological Society, on the 14th of March, 1868, a monster fatty tumor, weighing fifty-five pounds, removed after death from the abdomen of a woman. This case and an unreported one mentioned to me by Professor Calvin Ellis, of Harvard University, are the only ones I have heard of. Dr. Ellis thought that the one he removed after death might possibly have been successfully removed during life. In the first of these two cases I made an antiseptic exploratory incision and thought that I could not successfully remove the tumor, and in this opinion I was right. The patient recovered so easily and rapidly from this operation, however, that I felt emboldened to make another and more thorough attempt, which, I regret to say, resulted fatally.

CASE I. IMMENSE MYXO-LIPOMATOUS TUMOR WITHIN THE ABDOMEN.

Francis, C. G., a porter, thirty-nine years old, a native of Germany, came to Boston at the age of ten, and has lived here since. In July, 1861, he enlisted in the 20th Massachusetts infantry, and served gallantly through the war. He was for four months a prisoner in Libby prison during the early part of his enlistment, and later lost his left fore-arm at Fredericksburg, in the assault under Burnside; he was never otherwise sick nor injured. After he returned from the war he worked as janitor and porter in a large office building and carried heavy ash-barrels, weighing one hundred and fifty pounds apiece, down five flights of stairs, by swinging the barrel on his back and holding it by the handle with his right hand over his shoulder. He also carried hods of coal up-stairs, and had the care of twenty-five fires during each winter. He gave up his place in 1879, and was afterwards unable to find work that he could do.

During 1879 and 1880 he did not feel strong and was troubled with palpitation, heart-burn, loss of strength and ambition, and more or less loss of mental power. After standing a few minutes he would feel numbness in both thighs as though they were "asleep;" this sensation induced him to sit down, but if he struggled against this desire and walked about the feeling disappeared. Until the summer of 1880 he had had no dyspnœa. He had never had syphilis. He had been in the habit of drinking two glasses of lager beer daily for about eight years, and had smoked tobacco somewhat. He had not slept very well during the year 1880. Two and a half years ago — that is, in 1878, he first noticed that his belly was becoming swollen, but he thought that it was a natural increase of size, and that he was simply growing stout. In the early part of 1880 he began to lose flesh and strength, and became gradually more and more emaciated. He entered the Massachusetts General Hospital in February, 1881, and remained about three weeks. No definite diagnosis was made. The urine was somewhat diminished in amount, but not remarkably so. I saw him in July, 1881. The tumor had grown considerably larger than it was when he left the hospital. His abdominal girth at the umbilical level was forty-two and three fourths inches, and from the ensiform cartilage to the pubes the distance was eighteen inches; from one anterior spinous of the ilium to the other was twenty-two and one fourth inches.

As all of the patient's symptoms could be accounted for by the presence of the abdominal tumor it will be unnecessary to refer particularly to the different organs of the body, except to say that they were essentially healthy as far as could be ascertained. A careful examination of the abdomen was made many times. There was a uniform bulging in every direction, and the distended walls projected somewhat over the thighs. The tumor felt so fluctuating in parts that it was punctured several times, but only a little bloody fluid was obtained. This was examined by Dr. Gannett, and the following is his report: —

6 PARK SQUARE, *Aug.* 3, 1881.

DEAR DR. HOMANS, — The fluid, of a dark-brown color, very opaque, gives slight precipitate with nitric acid. On standing, abundant brown sediment, clear supernatant fluid. Microscopically sediment made up of very numerous fresh red blood corpuscles and a *large* amount finely granular material, wholly soluble in acetic acid. No cells of any sort were found, and nothing to indicate the origin of the fluid. From its solubility in acetic acid, the granular matter is undoubtedly albuminoid. I am unable to make any diagnosis from the few characteristics found in the specimen. Sincerely, W. W. GANNETT.

My diagnosis was "a tumor of unknown character in the abdomen without much adhesion, apparently a large myxoma, or a lipoma, or a colloid growth.

After many examinations and consultations a room was hired in the Carney Hospital, and the patient's board was paid by a subscription of his comrades and friends in the 20th Massachusetts regiment and elsewhere, and on October 30, 1881, I made an incision under the antiseptic spray, about fifteen inches long, from above the umbilicus to the pubes. The tumor, on being exposed, looked like an ordinary fatty tumor. It was smooth and lobulated. It was slightly adherent to the liver, and was covered with a delicate, smooth, envelope looking like peritonæum. It seemed to be about two feet long and a foot thick. The incision enabled me to pull the tumor out of the abdomen considerably, and it was found that the envelope covering it ran down to the spinal column and was then reflected upon the parietes. No intestines were seen. At the lower part there were no adhesions to the bladder, but the tumor seemed to have a central attachment extending from the neighborhood of the cœliac axis downwards and sideways on both side of the vertebral column, covering a space considerably larger than the palm of the whole hand. My explorations were made for the most part on the left side of the abdominal cavity, and after ascertaining with some indefiniteness the attachments of the growth my courage gave out, and I thought it wise to replace the tumor and close the incision. It seemed a shame to shut up this great mass again in the poor fellow's abdomen, but I was afraid that I could not control the hæmorrhage accompanying its removal, and I feared that some of

[1] Read before the Boston Society for Medical Improvement, December 11, 1882.

the abdominal organs, particularly the intestines or a kidney, might be included in the tumor. It was with the greatest difficulty that the tumor was pushed under the abdominal parietes, and behind the pubes, and held there by three strong men while numerous stitches brought the edges of the incision together. Finally fifty-six stitches held the wound firmly, and the tumor remained within the abdominal parietes. The patient recovered completely from this exploratory operation, and showed great strength of constitution. His convalescence was accompanied by much pain and diarrhœa, but the wound healed rapidly and solidly. He returned home at the end of four weeks and gained strength quite fast. He gradually increased his exercise until he began occasionally to come to Boston (from Cambridgeport, where he lived, a distance of about two miles) in the horse-cars. The weight of the tumor annoyed and distressed him, but he found it much easier to carry after his wife had made a stout supporting sling, held up by straps over his shoulders.

As time went on he became anxious to be relieved of his burden in order to be able to work and earn his living. After due consideration and reflection we decided to remove the tumor. Mr. G. said, "My life will not last long with this increasing burden, and if there is such a thing as removing the tumor I wish you would do it. I am not afraid to die, doctor, and it 's neck or nothing this time." From the knowledge obtained at the exploratory operation, and from the endurance the patient had shown, I began to think that perhaps I *could* safely remove the tumor; that perhaps its attachments were not inseparable, and that perhaps I ought to have persevered when I had operated before. Whether our decision was wise or foolish the operation was decided upon. On the 5th of February, 1882, I made another attempt, assisted by Drs. A. T. Cabot, E. G. Cutler, M. H. Richardson, F. C. Watson, Mixter, Russell Sturgis, and Messrs. Sparhawk, Holden, Godding, and several others. Two tumors, weighing with their pails fifty-seven pounds, were removed. An incision about seventeen inches long was made to the left of the scar of the exploratory incision, and a transverse one about four inches long was made on the left side at right angles with the longitudinal one. The large, lobulated, fatty tumors had no anterior adhesions except to the cicatrix of the former incision, but they were adherent to the ascending colon, which crossed them transversely. The tumors seemed to have originated behind the peritonæum on the right side, and had pushed all the bowels towards the left side except the ascending colon. If these tumors had been situated outside the skeleton (that is, outside any of the great cavities of the body) they could have been safely enucleated. They were covered with a capsule, and from this they could be peeled out. The capsule was more or less torn and ruptured, and the tumor raised with great difficulty owing to its weight. The ascending colon was separated from the tumor and rolled off, after dividing and tying most of its mesentery. The vascular attachments were clamped and tied and burnt off from time to time as was necessary, and the tumor was lifted out of the abdomen. When this tumor was removed another one, apparently purely myxomatous, was exposed to view. After some hesitation this was removed also. It occupied the right lumbar and hypochondriac regions, and had pressed the liver upwards and to the left into the epigastrium. The shining capsule (peritonæum) of this tumor was tough and strong; some of it was removed with the growth, and some of it was peeled off and left behind. All bleeding points were secured and the abdomen thoroughly cleaned. Another tumor was now seen, about ten inches long and lying on the abdominal aorta, pulsating with it. This was not disturbed. Everything looked as favorable as one could expect after so severe an operation; there had not been much blood lost; the pulse was 85, and feeble, but not extremely so. Two atomizers had played a spray of a five per cent. solution of carbolic acid upon the abdomen, and the operation had been thoroughly antiseptic. The intestine which had been pushed off the tumor, or rather from under which the tumor had been withdrawn, was largely deprived of its mesentery and might not be well nourished, but with this exception affairs looked as promising as after a severe successful ovariotomy. The patient was placed in bed with his feet elevated and warmed with hot bottles. The operation lasted an hour and a half. During the afternoon (the operation having been finished at half-past twelve) he seemed to be doing well, and at half-past five asked for a drink of water. His wife brought it to him, when he said, "I think I am going," and died.

I append an account of the autopsy and a description of the tumors, by Dr. W. W. Gannett, who has kindly written them out for me.

Autopsy, February 7, 1882, forty-six hours after death. Body medium size, fairly developed, considerably emaciated.

Anterior abdominal walls flaccid, flabby, and thrown into numerous folds. A linear incision from about ten centimetres below xiphoid cartilage to pubes. Short cross incision at umbilicus stitched together. In abdominal cavity about fifty centimetres of bloody fluid. Ascending colon hung free like a rope in the abdominal cavity, having no meso-colon, its usual point of attachment showing a reddened, ragged edge. The whole posterior right wall of the abdominal cavity a ragged, irregular surface (from this the tumors had been removed). On the left side, posteriorly to the peritonæum, was a flattened round mass the size of a man's head showing the same fatty mucous structure as those previously removed. Another mass, about three times the size of the first and of the same structure as the preceding, lay over the inferior vena cava, and was adherent to it and to the duodenum. The right kidney was of the usual size and density and of a pale color. On section it showed a yellowish opacity of the cortex (moderate degree of fatty degeneration). The left kidney was apparently normal. The other organs presented no unusual appearance. The head was not examined. The tumors were retro-peritoneal.

DR. GANNETT'S REPORT OF THE TUMORS REMOVED FEBRUARY 5, 1882.

A. A flattened globular mass measuring $38 \times 33 \times 12$ centimetres, and weighing twenty-five pounds and three quarters. The outer surface showed a shreddy, glistening white surface, from which numerous thin connective tissue layers can be picked off. One portion was hanging loose, and a mass of connective tissue about 20×20 centimetres and about three millimetres thick formed a thick, tough membrane, the under surface of which (corresponding to the tumor) was ragged, the upper smooth and shining. The density of the mass was about that of firm wine jelly. On section the cut surface shows a very delicate pale connective-tissue

meshwork inclosing large spaces which were filled with a thick, syrupy, pale yellow, almost translucent fluid coagulating on the addition of acetic acid.

B. (The scond tumor.) A coarsely irregular mass of pale yellow color and somewhat doughy consistency, measuring $37 \times 31 \times 16$ centimetres, and weighing (with the mass next to be described) twenty-four pounds. On section the surface showed twofold appearances. A homogeneous opaque yellow tissue resembling fat tissue. Imbedded in this were grayish, homogeneous, translucent, soft, gelatinous nodules varying in size from that of a filbert to that of the fist. On scraping the cut surface of the latter a thick, homogeneous, nearly transparent fluid is obtained.

C. A mass similar in character to the last (B), which was torn away from it during the operation of removal, measures $34 \times 17 \times 15$ centimetres, and weighs (with B) twenty-four pounds, and presents the same appearances.

D. Several smaller nodules of a flattened globular form, varying in size from a walnut to a large peach. On section presenting a somewhat translucent yellow, as if made up of a fat tissue rich in connective tissue.

Microscopic examination of gelatinous portions of the above-described tumors (frozen and sections made) showed a stroma made up of very delicate connective tissue fibres running in various directions, and inclosing spaces in which was a clear refractive substance giving a marked mucin reaction. The remaining portion showed the structure of fat tissue.

Case II. On August 8, 1881, I saw Mrs. V., sixty years old. I learned that she had always been well and strong, and had had several children. Her father died at the age of sixty-six of cancer of the rectum, and a brother had died of cancer of the liver. On examination I found a large fluctuating abdominal tumor, without impulse, and containing solid masses. During the previous six months it had grown rapidly. The umbilical girth was forty-one inches. I aspirated the tumor in many places where fluctuation seemed most distinct, but got no fluid, not even blood. I found that the abdominal parietes in the pubic region were œdematous, and that the lower extremities had been so. Her complexion was somewhat sallow, but had formerly been ruddy. The next day I saw her again, and aspirated with quite a good-sized needle, but could get no fluid, though I think that any medical man would have been almost willing to swear that the tumor was a cystic one filled with fluid. On account of the result of my tapping, and because of the family history, I decided not to recommend an operation. Mrs. V. was bright, sagacious, and sensible. I suggested an exploratory incision at some future time, but rather discouraged any interference. At the close of our interview she said, "Will you come to me, and try to remove this tumor, if I send for you?" I promised that I would do so. She went home feeling that if her situation should become very desperate she should insist upon my keeping my promise.

Accordingly, in March, 1882, at her request, I operated at her home. Her size had increased very much, and her umbilical girth was fifty-three inches; the œdema of the abdominal walls was greater, and her lower limbs were much swollen. The tumor was exposed by a long incision, and appeared to be an immense lipoma. It had originated on the right side, behind the peritonæum, and as it grew had pushed the bowels before it, as in the previous case. It was adherent to the peritonæum, from which it was more or less neatly enucleated with free hæmorrhage at times. The ascending colon crossed over it, as in the previous case, and the cæcum, colon, and appendix cæci were almost incorporated in the mass. The tumor dipped deeply into the pelvis, and almost filled it, and was at length, after considerable hæmorrhage and much shock, removed. The operation lasted about an hour, and the tumor weighed thirty-five pounds. Mrs. V. never rallied, and died soon after being placed in bed.

Dr. Gannett reported that the tumor was a pure lipoma.

It seems to me proper and important to put these cases on record. The propriety of operating is, of course, open to discussion. It is very hard, however, to stand by and see persons sink slowly away from mechanical pressure, which you cannot remove by tapping, and make no effort to relieve them, and we are able to do so much now in the way of abdominal surgery that I felt encouraged to make these efforts.

Mr. Cooper Forster showed, March 14, 1868, a monster fatty tumor, removed post mortem from the abdomen of a woman he had been asked to tap. Both Dr. Wilks and Dr. Hicks believed it to be a collection of fluid, the percussion wave being perfect. The ascending colon lay in front of the tumor, and there was a little fluid between it and the walls of the abdomen. It was adherent to the diaphragm, and when removed weighed fifty-five pounds. It had no distinct pedicle, so it was a question how it originated.

The case of Mr. Forster is printed in the *Medical Times and Gazette* for 1868, vol. i., p. 300, and for the reference I am indebted to Dr. Neale's Digest.

It will be seen that these two tumors I have described and the one exhibited by Mr. Cooper Forster were crossed by the ascending colon, and it would seem impossible to remove such tumors without disturbing the vascular connections to such a degree as to cause gangrene. In another case I should be rather inclined to make an artificial anus in the cæcal region, or resect the intestine that had been deprived of its mesentery. The latter procedure would be extremely difficult in the case of the ascending colon, which is much bound down in the right lumbar region. At my request Dr. Gannett has carefully searched all the German, French, and English periodicals and publications, but has not found a single case of retro-peritoneal fatty tumor. Fatty tumors of the omentum and mesentery are not very unfrequently described. Leopold [1] and Kroner [2] have collected seventy-six cases of extirpation of the kidney, but none for fatty or mucous tumors. One of these was a retro-peritoneal fibroma, removed by Billroth.[3] Bruntzel, Breslau, reports [4] an extirpation of the left kidney for a fibroma of the renal capsule, weighing thirty-seven and a half pounds, and followed by recovery, with a fæcal fistula. The patient was an unmarried woman, thirty-three years old. The tumor was of eight years' growth, and painless. Bruntzel's treatment of the wounded and torn peritonæum is interesting and instructive. In removing the tumor (which was retro-peritoneal) the peritoneal sac was twice incised. The two ragged posterior peritoneal surfaces were brought into contact, and the anterior edges were stitched to the anterior abdominal wall in

the lower part of the incision, thus providing for drainage from the space between the two folds. The paper is a highly interesting one, and is made clearer by two wood-cuts. The tumor was a fibroma with considerable fat tissue in it.

OCULAR SYMPTOMS AS LOCALIZING SYMPTOMS.[1]

BY S. G. WEBBER, M. D.

THE third case was one of temporary, intermittent paralysis with conjugate deviation. As the symptoms were described to me at first, without seeing the patient, I ventured to guess that it was a case of epilepsy, and suggested the use of bromide of potassium until I could see her a day or two later. This drug did not give relief, and when the patient was seen and carefully questioned and examined, it seemed possible that the symptoms might come from local disturbance of circulation, or that there was some small spot of degeneration.

The result supports the view that the early symptoms were caused by a disturbance of the circulation, continuing only a short time, and that then the blood took again its normal course. The extensive atheroma of the arteries, and the great change in the basilar and its branches, renders such a temporary interruption of the circulation quite probable.

Benjamin Ball [2] reports cases of paralysis which he thinks were due to "contraction of the vessels supplying certain provinces of the encephalon, without structural change, either in the vessels themselves or in those parts of the brain the functions of which were momentarily suspended." He thinks this "spasmodic contraction of the brain vessels may persist for a considerable length of time without producing structural changes in the nervous centres;" and that "the morbid condition may, in certain cases, suddenly disappear, while it is not unreasonable to suppose that the converse may be equally true, and that the symptoms may culminate in rapid or even sudden death."

CASE III. INTERMITTENT LEFT HEMIPLEGIA, WITH CONJUGATE DEVIATION TOWARDS LEFT; DISEASE OF ARTERIES, PLUGGING OF BASILAR; SOFTENING IN PONS AND CEREBELLUM.

Mrs. A., aged about seventy, had been very well all her life, though during three years she had had considerable worry and anxiety as well as grief in the sickness and death of children and husband. Three months before she was seen she was suddenly attacked with flushing of the face and a sensation as if she was about to faint; she sank into a chair; the left arm became powerless, there was a tingling sensation in the hand, and then motion was restored; there was no loss of consciousness. The same day she had another similar, though less severe attack; after that none for several days. They recurred at varying intervals, were lighter, but became more frequent; they had the same characteristics; there was no pain, and no loss of consciousness. After the attack there remained a tingling or numb sensation in the fingers.

There was no paralysis of the leg, simply a slight weakness; once or twice there was tingling in the left leg. Only once was it thought by a daughter that the right side was affected and the left not.

The left side of the face was paralyzed, at least in some of the attacks, the eyelids closed, the left eye turned outwards.

During the attack she could articulate; many of them occurred in the night or early morning, some during the day.

When seen there was nothing abnormal to be noticed in the motions of the eyes, pupils, face, tongue, or hands; she did not walk very firmly, but there was no unsteadiness; sensation was normal; the ophthalmoscope showed no change in the fundus of the eye.

A week later she was worse, had had several severe attacks of paralysis on the left side, then both eyes were turned to the left, the lids were closed most of the time; no observation was made as to whether she could move her eyes to the right. The left hand continued to feel numb all the time, even between the attacks. Once all four limbs were paralyzed, and she was unable to speak; a dose of whiskey seemed to restore motion and speech.

Finally, during Thursday night, she had an attack, the respiration became stertorous, the paralysis varied from side to side, sometimes the right side seemed paralyzed; the eyes did not deviate; Cheyne-Stoke's respiration for twenty-four hours, then it was regular in rhythm, but shallow; the next morning she seemed to recognize some who were about her; Saturday she died.

The autopsy was made three days after death, with the assistance of Dr. Broughton. The skin was very yellow generally. Dura mater was very adherent to the skull; the convolutions of the brain were shrunken, but not more than might be expected; the space left by this shrinking was filled by serum in the meshes of the pia mater, which was not thickened. There was a deeper depression at the upper part of the right anterior central convolution than elsewhere. No adhesions of the pia anywhere. The arteries at the base were very generally atheromatous, but seemingly not more so on one side than the other. The basilar artery, at about its middle, was entirely plugged up by a firm, light-colored clot; there was no coagula either side of this clot, indeed, very few coagula were found anywhere. For one inch in length the basilar artery was very atheromatous, and gave off only small branches, excepting one rather large running to the left, which, however, was nearly closed by the atheromatous thickening of its walls.

Both crura tore easily in taking out the brain, and seemed softened; the upper and anterior portion of the left lobe of the cerebellum was very soft; in the right half of the pons, just anterior to the fifth nerve, and apparently among the pyramidal fibres, was a discolored softened spot. At this point in the pons, and more markedly in the softened tissue of the cerebellum, the microscope showed granular corpuscles about the vessels and in the nervous tissues, also fat corpuscles about the vessels. The crura cerebri were not changed.

The posterior lower portion of the lower lobe of the right lung was dark red, solid, without air, the vessels pervious.

The aortic and mitral valves contained extensive calcareous deposits, the edge of the mitral valve was thickened, and contained a very large amount of this deposit.

The kidneys had thin cortices, the capsules were slightly adherent; post-mortem staining. Spleen small. All other organs normal. The blood was very fluid,

[1] Concluded from page 220.
[2] British Medical Journal, October 30, 1880, page 693.

and there was much post-mortem staining of the viscera.

After hardening the specimens, thin sections were made through the diseased portion of the pons. The hardening was not entirely satisfactory, as the specimen was put into alcohol a little too soon. The spot of softening in the pons (Fig. 4) was about one quarter inch in its longest direction, and about one eighth in transverse direction; it was situated obliquely, near the middle of the right half of the pons, not quite reaching the median line, not implicating the sixth nucleus. On section, parts of the altered tissue fell out, leaving ragged edges. In several spots the blood-vessels were very prominent from the débris having partly fallen away from them. In many places the axis cylinders were enlarged. This softened spot did not extend quite to the point where the fibres of the sixth nerve cross the pons.

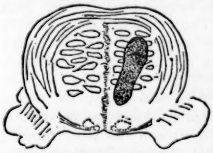

Fig. 4. Showing the size and location of the spot of softening in the Pons. Natural size.

The localizing symptoms were very few; probably had she been seen during one of the attacks more positive symptoms would have been noticed. There was left hemiplegia, with conjugate deviation of the eyes to the left, at least in some of the attacks. This would indicate lesion of the pons, and such a lesion was found. It is not possible to explain the intermittent nature of the symptoms, unless we suppose that at first there was simply a change of blood supply, and when the circulation was restored there was an intermission in the deviation; later the vessels became more occluded, and then the destruction of tissue took place, yet not over an area sufficient to cause permanent deviation; finally the vessels were affected on both sides, and so there was no deviation.

CASE IV. OCCLUSION OF LEFT POSTERIOR CEREBRAL ARTERY; CONGESTION AND SOFTENING OF NUCLEUS OF SPINAL ACCESSORY AND PNEUMOGASTRIC; PARTIAL PARALYSIS OF OCULAR MUSCLES ON THE LEFT; AT LAST CONJUGATE DEVIATION TOWARDS RIGHT.

Annie W., aged seventy, was admitted to the City Hospital December 6, 1881. Her mind seemed clear, but she could not speak above a whisper. Said she could talk aloud one week ago, that she had been sick about ten days. There had been no injury. The mouth was drawn slightly to the left; the tongue was protruded straight; there was less power in the left arm than in the right; there seemed to be less power in the right leg, and sensation was almost wholly lost in that leg; the reflex action was exaggerated in the left foot; striking the bottom of either foot caused severe pain. Incontinence of urine. Slight œdema of ankles and feet.

The next day when seen she could not make herself readily understood. Tickling the eyelids caused reflex action in both lids; both pupils were small, the right smaller than the left; the left lid drooped; motion of the eyes was somewhat restricted towards the left. The tongue was protruded straight. There was little power in moving either hand, attempts at voluntary motion resulting only in tremor; passive motion of right arm showed a contraction of the muscles of that arm, and caused pain; there was no contraction of the left arm; passive motion of right foot also caused pain and a tremor afterwards; no ankle clonus; on irritating soles of feet the left was slightly withdrawn, the right not at all; there was slight hyperæsthesia to pressure over the legs. After being aroused she quickly relapsed into a semi-comatose condition.

The third day the inequality of the pupils was more marked. She could move both hands, the right better than the left; there was still great tremor on making an effort at voluntary motion.

The fourth day it is noted that the eyes could turn to the left, not to the right. The nurse reported spasm of the fingers and disturbance of respiration. In the the afternoon she died.

Autopsy by Drs. Cutler and Gannett. The left posterior cerebral artery was atheromatous from its origin to its junction with the posterior communicating; it was very much smaller than the right, and seemed to be impervious to blood; air could not be blown through it. The left posterior communicating was much larger than the right; all the other arteries of the brain were healthy, and rather full of blood.

The left side of the pons from about midway between the origins of the fifth and seventh nerves was flattened anteriorly as compared with the right side. The left crus cerebri was apparently smaller, and its foot less distinctly striated than the right, and had generally a softer appearance. On section of pons and crura the antero-posterior and lateral diameters on the left side were diminished as compared with the right. All other parts of the brain were normal.

The heart was healthy, and no change could be discovered which was likely to give rise to an embolus. The thoracic aorta contained several atheromatous patches.

No recent disease in lungs or elsewhere in thoracic or abdominal viscera.

After hardening it was seen that the blood-vessels of the medulla, pons, and crura cerebri were unusually full of blood, especially those belonging to the gray substance, so full that even the smallest vessels were distinct as if injected artificially. A portion of the gray substance about the aqueduct of Sylvius was very easily broken down, and good sections could not be made through it. This friable portion did not include much of the nucleus of the third nerve; wherever that could be examined the cells seemed to be normal in character and number. A very few small hæmorrhages were to be seen to one side of the third nucleus or in the tegmentum of the crura.

The region of the sixth nerve and its nucleus showed much injection of the blood-vessels. There was no discoverable change in the nerve cells of the nucleus. Just internal to the left eminentia teres, the descending portion of the facial, was an enlarged blood-vessel, with a greatly dilated perivascular canal. This enlarged vessel was much larger than any usually found in that position, and had pressed the seventh nerve out of place. It commenced a few sections below the nucleus of the sixth nerve, and could be followed for a distance above where all traces of the sixth nucleus were lost. Was this the course taken by the blood in the collateral circulation to supply the plugging of the posterior cerebral?

A hæmorrhage was to be seen in the nucleus of the spinal accessory, and around this the nerve tissue was friable, and sections were more or less irregularly

broken; the hæmorrhage and irregularly-broken masses included on one section at least the whole of both accessory nuclei. The hypoglossal nuclei were seemingly normal.

A section made somewhat higher, so as to include the vagus nucleus (Fig. 5), showed a similar friable

FIG. 5. Showing injection of small vessels in vagus nucleus. At upper part of figure the tissue is softened. At lower part the hypoglossal nucleus is seen in normal condition, magnified eleven diameters, then reduced one-third.

condition for a short distance on each side the median fissure in the floor of the fourth ventricle. There were a very large number of pigmented cells along the borders of the vagus nucleus; such cells are normally found here, and the patient's age may account for the number. The vessels within the limits of the vagus nucleus and along the gray substance lining the floor of the fourth ventricle were very full and prominent. This congestion did not extend into the hypoglossal nucleus. On the left, near the median fissure, blood had escaped from a vessel just under the floor of the fourth ventricle; possibly this was a continuation of the small hæmorrhage seen at a lower level.

A section a short distance above this was normal.

The diagnosis made during life was — lesion involving the nucleus of the left third nerve; probably obstruction of the left posterior cerebral artery. This diagnosis was made from the fact that there was a decided difference in the two eyes. The left eyelid drooped; the left pupil was the larger. My impression is that the restriction of motion was greater than the record implies, and was much more marked with regard to the left eye than the right, and the conjugate deviation towards the right was a later symptom.

It was supposed that the lesion was recent, and was connected with the cause of death. Having no previous knowledge of the patient this was not unreasonable.

The autopsy showed no gross change in any organ as cause of death. The occlusion of the posterior cerebral artery was evidently an old lesion, and probably the ocular symptoms were also of long standing.

The congestion and softening found in the medulla must be considered as the cause of death. The small hæmorrhages may have occurred only towards the close of life. The changes in this region implicated the most vital nerve nuclei, the spinal accessory and pneumogastric.

On the last day of life the respiration was disturbed. The nature of the disturbance was not learned.

The temperature rose almost without interruption till the morning of the day on which she died it was 103.5° F.

There was no definite lesion found to explain the conjugate deviation. Sections were made through the whole of the sixth nucleus, twenty or more, and each one carefully examined. The deviation was probably due to disturbance of blood supply, or to the plugging of some vessels which gave rise to no marked change of structure.

Kahler and Pick report [1] a case somewhat similar to this. There had been ocular symptoms pointing to lesion of the third nerve for several months preceding death. Death resulted from cerebral hæmorrhage in another part of the brain. A spot of softening was found in the right tegmentum implicating the fibres of the third nerve as they passed from their nucleus.

The same authors report [2] another case with left hemiplegia, left facial paralysis, right ptosis, and paralysis of the right rectus superior and inferior; rectus internus only partially paralyzed; pupils normal; there was occlusion of the right posterior cerebral artery.

In connection with the above the following case is of interest, although there was no autopsy. There was some cause of irritation acting upon the nerve tract for the left limbs, the spasm being that which has been named "early contraction." We cannot doubt that the same irritating lesion caused the conjugate deviation to the right; as the limbs were in a state of spasm, we must conclude that the ocular muscles were also in spasm. The contraction of the ocular muscles was relaxed during sleep or coma; it is not stated whether the same was true as to the limbs.

From these symptoms we must conclude that the lesion was in the pons. Its nature is less clear, as the first attack was probably from embolism. It is probable the second arose from embolism also.

When the contraction was diminishing the right eye was directed upward and outward, the left eye was almost straight. The position assumed by the right eye has been referred to a lesion of the middle cerebellar peduncle, especially if the other eye is directed downwards and outwards.

CASE V. RIGHT HEMIPLEGIA AND APHASIA; PARTIAL RECOVERY; PERSISTENT SPASMODIC CONTRACTION OF LEFT LIMBS; CONJUGATE DEVIATION TOWARDS THE RIGHT; DEATH; NO AUTOPSY.

Minnie L., aged thirty-seven, entered hospital November 23d. She had had rheumatism about four years previous; dyspnœa and palpitation on exertion for some time. Three days before admission, on awaking, she could not talk so as to be understood. That afternoon, on trying to rise from a chair, she found that the right arm and leg were paralyzed. She was sure she did not lose consciousness, and that her face was not drawn to one side. She regained partial use of leg and power of speech.

On examination there was seen to be slight paralysis of the right side of the face, tongue was protruded to the right. The upper branch of the seventh was not affected, both eyes closed readily, and the forehead was raised naturally on both sides. There was entire pa-

[1] Arch. f. Psych. u. Nervenk., x., 1880, p. 334.
[2] Zeitschr. f. Heilkunde, ii., 1881, p. 301.

ralysis of the right hand and arm. She could move the right foot, though not so strongly as the left. Reflex actions were retained. Sensation did not seem to be materially impaired in either hands or feet. There was a loud double murmur connected with the aortic sounds, and enlargement of the heart. There were fine râles at the base of the left lung behind.

So far this is a simple case of embolism stopping up probably the left middle cerebral artery. The only other point of interest in the early history is that the evening temperature continued steadily above 101° F. until a week after entrance, November 30th, when it fell to 100° F.; and on December 2d to 99.4° F. It is not unlikely that the pulmonary complication kept this temperature up. She improved, gaining control over the right arm and more motion in the right side of her face.

December 2d. At evening visit she was found by the house officer to have lost the power of speech, the left fore-arm was contracted in flexion on the arm; both eyes were turned to the right. The right arm and leg moved very freely.

December 3d. At the visit she was lying with both eyes closed as if asleep. When the lids were raised there was slight external strabismus of right eye, the left eye being directed forward. When fully roused the conjugate deviation to the right returned with slight nystagmus of a rotatory character. The pupils were about medium size, reacted so little to light it was difficult to decide whether they varied in size or not. Her jaws were firmly closed. The left arm was spasmodically flexed at the elbow, and strongly adducted, and passive motion was resisted. The fingers and hand were kept semi-flexed, but did not resist passive motion. The left leg was extended, passive motion at the knee was less free than on the right. Reflex action was absent on the left, present on the right. Sensation to pinching was retained in the face and hands. She moved the right arm slightly at the elbow during the examination, also the hand and fingers when they were irritated. She answered no questions, but gave response to what was asked by motions. When left to herself she relapsed into a comatose condition, and the eyes took the position noticed at the beginning of the examination.

She became gradually more stupid, could not be induced to take food by the mouth, and was fed per rectum.

December 7th and 8th the contraction of the arm was somewhat less strong, and the conjugate deviation less constant, though returning when she was aroused. During December 12th and 13th there was still less contraction, and she began to take milk by the mouth; on the 14th, taking a pint and half, and on the 15th, a quart. The right eye was then directed upwards and outwards; the left eye slightly inward, almost straight. Contraction of the left arm was much diminished.

December 16th. She took a quart of eggnog and retained two enemata, each consisting of one egg beaten up with pepsin.

December 17th. At 2.45 P. M. she died.

In the first of the above cases the conjugate deviation was towards the paralyzed side away from the lesion, as it should be theoretically. In the second case the same is true as to the conjugate deviation and the lesion, but the paralysis or weakness was exceptionally on the same side with the tumor. The ocular symptom was more trustworthy for localization than the paresis. In the third case both the conjugate deviation and the paralysis were intermittent. If the spot of softening found in the pons can be considered proof of serious disturbance in the circulation of that side before the last days of life, the symptoms in this case also followed the rule. In the fourth case the conjugate deviation was more marked on the day before death than previously; the other ocular symptoms led to a diagnosis which proved correct. At the autopsy the nucleus of the third nerve was cut into so that the microscopic examination was not perfectly satisfactory, as sufficient sections could not be made to be certain of the condition of that nucleus.

Conjugate deviation of the eyes may then, judging from these cases, be regarded as a localizing symptom. When the eyes are turned away from the lesion and towards the hemiplegic side, there is reason to believe the pons is affected; if, however, there is spasm, the eyes will be turned away from the affected limbs if the lesion is in the pons. Bernhardt[1] says that when there is paralysis of the abducens on the same side with tumor, combined with paresis of the opposite internal rectus, not fugitive but persistent, even without paralysis of the facial, it is a *certain* sign for lesion of abducens nucleus on the same side with the paralyzed rectus externus.

Many cases have been collected by Graux, Hunnius, and Bernhardt; experiments have been made by Duval and Laborde, which all show that the above symptom is as constant and safe for localizing as any others.

Wernicke[2] has reported a most interesting observation. There was paralysis of the left facial in all its branches, conjugate deviation of the eyes to the right, sensation was diminished on the right side of the face. There was no paralysis of the limbs as to either sensation or motion. A tumor projected into the fourth ventricle, which extended on the left of the median line from one and one half centimetres above the calamus to one centimetre below the corp. quadrig. The longitudinal fibres of the pons and medulla were not affected. Both third nuclei and right sixth nucleus were not affected. The left sixth nucleus and the left sixth and seventh nerves were diseased. This observation was made before the commissural fibres from the sixth nucleus to the third nerve were established. Wernicke's interpretation of this case was therefore not quite correct. He refers the conjugate deviation to a lesion of a coördinating centre for the third and sixth nerves, which he locates near the nucleus for the sixth.

The symptoms connected with lesion of the nucleus of the third nerve, if carefully observed and rightly interpreted, are also localizing symptoms. The two cases reported by Kahler and Pick are of value as proofs of this. Wernicke[3] has given three cases of hæmorrhage into the gray substance about the third ventricle and the aqueduct of Sylvius, where the ocular symptoms were prominent.

The conclusion must then be formed that the study of the motions of the eye is of great value as aid in localizing the lesion.

It would be easy to extend this paper by considering the value of isolated paralysis of the abducens nerve, and by reports of other cases where there was no autopsy, but this would not be profitable.

ARSENICAL PARALYSIS.[1]

BY CHARLES K. MILLS, M. D.,

Neurologist to the Philadelphia Hospital; Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic and College for Graduates in Medicine.

ON November 2, 1882, at Norristown, Pennsylvania, occurred a series of cases of arsenical poisoning almost without parallel. The poisoning was brought about chiefly through eating pumpkin-pie, which it was subsequently proved contained a large amount of arsenious acid. The story of the tragedy does not come within my province in the present paper.

On the 24th of December, 1882, I saw one of these cases at Norristown with Dr. E. M. Corson, the physician in attendance. On the 3d of January, 1883, he was brought to the Philadelphia Orthopædic Hospital and Infirmary for Nervous Diseases, to be under the care of Dr. S. Weir Mitchell. I am indebted to Dr. Mitchell for great courtesy in affording me the opportunity of thoroughly studying the case at the hospital, and now of presenting it to the college.

Dr. G. B. Massey, Electro-Therapeutist and Assistant Physician to the hospital, carefully studied with me the electrical reactions. The results of our examinations will be given at the proper place. Dr. Browning, Resident Physician, also rendered assistance in investigating and recording the case.

H. G., aged twenty-four, single, a lawyer, prior to Thursday, November 2, 1882, was in good health. He was taken sick immediately after rising from the dinner table, having eaten freely of the pie which was subsequently found to contain the poison. He had an attack of vomiting which lasted a few minutes only. He had several similar spells of vomiting during the afternoon, and from Thursday night until Saturday morning the vomiting was almost continuous. It then began to subside, ceasing entirely Monday afternoon, except that at two o'clock Tuesday morning he vomited a dark grumous mass. Just before vomiting this mass he had a sensation of constriction or contraction in the muscles of the chest and throat, and the facial muscles were much contorted. He was not purged at any time; in fact, his bowels were not opened from Thursday, November 2d, until Wednesday, November 8th. During the whole time that the vomiting persisted he had but little pain, scarcely more than would be accounted for by the retching and vomiting. Prostration was very great from the first. Tuesday night, November 7th, he attempted to get out of bed, but fainted, and remained for some time in a semi-conscious state. About this period he began to have marked fever.

On Wednesday, November 8th, and therefore six days after taking the poison, the patient noticed for the first time a sensation of aching and numbness chiefly about the knees. The numbness continued, and, in a few days, extended towards his feet. He still, however, had fair use of his legs, although, of course, they were extremely weak. Three days after the appearance of the numbness in his lower limbs the same sensation began in the fingers of both hands, and soon extended to the wrists, beyond which it never passed. His brain remained unaffected. His legs below the knees were now almost completely paralyzed, and there was some loss of power below the elbows. His face was considerably puffed and swollen.

[1] Read before the College of Physicians of Philadelphia, February 7, 1883.

His general condition and his special symptoms remained as just recorded, without any change worthy of note, until December 1st, four weeks after the ingestion of the arsenic, when he began to suffer great pain. The pains began in the knees, and speedily invaded the legs below the knees, and the feet, progressing in the same course as the numbness had previously taken. Aching was always present, but frequently the pains were boring, tearing, or lancinating. They were accompanied by a sensation like that produced by a strong faradic current. Two days after the coming on of the pain in the legs the fingers and hands also became the seat of aching. In one week the pains began slowly to abate; but throughout December, and, indeed, up to the present time, he has had more or less pain, varying very much in character. By the middle of December the numbness and aching, which had previously been below the knees, had extended above them a distance of several inches. His lower extremities felt as if encased in a cylinder as high as the limits of the numbness. The symptoms in his upper extremities did not change noticeably. The loss of power in the thighs increased with the spreading upwards of the sensory perversion.

I will now give the results of my examinations into the condition of the patient. He was first examined by me December 24, 1882, but the notes here given are from examinations made between January 10 and January 17, 1883, nearly two months and a half after the poisoning.

He presented no brain symptoms, and no disturbances of the special senses of sight, hearing, taste, or smell. He slept fairly well until midnight, and then usually restless and unable to get into a comfortable position. He was much emaciated. Wasting of the limbs was extreme. The following measurements were taken: Circumference of right thigh 11 inches; left thigh 10 3-4 inches; right calf 8 1-4 inches; left calf 8 1-4 inches; right arm 7 inches; left arm 7 inches; right fore-arm 6 1-2 inches; left fore-arm 6 1-4 inches.

Paralysis below the elbows was marked, but not complete. The extensors and supinators were most decidedly affected. The fingers could only be flexed about one half. Movements of the thumbs and the small movements of the fingers were impaired. The loss of power was slightly greater in the right limb than the left. The following were the registerings of the dynamometer: Right hand 35; left hand 35. At both elbows were marked contractures at about right angles. The angles could be reduced to about 160°, but any attempt to carry the straightening further caused pain in the flexor tendons.

Both legs were paralyzed completely below the knees. All movements of the toes and feet were abolished absolutely. The legs in their entirety showed a tendency to rotate outwards, the feet, however, assuming the equino-varus position. Contractures were not present at the knees, but at times the limbs would assume a semiflexed position, these acts of flexure being accompanied by cramp-pains in the flexor muscles of the thighs. He had these jerkings both in the legs and arms not infrequently.

The bowels were very torpid, requiring cathartics. Some dribbling of the urine occurred for a few days in the early part of January, and then passed away. For a few days, also, he had some pain, which he referred to the lower part of the urethra, just as the discharge of urine was completed. At the time of examination,

January 17th, the urine was passed slowly, but without pain. The urine showed an excess of phosphates; but neither albumen nor sugar was present.

Farado-contractility was abolished in all muscles below both knees. Above the knees the extensor and flexor groups and the sartorius were examined, and the faradic reaction was found to be greatly diminished, but not wholly absent. The response was better to nerve than to direct muscular applications. The muscles below the knees would not respond to weak galvanic currents. To currents of medium strength they responded, but not normally.

The reactions were those of degeneration. Anodal closing gave the strongest reaction; cathodal closure came next. Slight contractions followed both anodal and cathodal opening. The contractions were at first sluggish, though vigorous, increasing after a few trials, and then quickly exhausting. The reactions expressed in the German formula were —

AnSZ″; KaSZ; AnOZ; KaOz.

In both upper extremities farado-contractility was decreased, but not lost; the diminution was much greater below than above the elbows. Below the elbows the faradic excitability was rapidly exhausted. To the galvanic current the reactions of degeneration were present, but not so decidedly as in the legs. Anodal closing gave stronger reaction than cathodal. With moderately strong currents tetany was produced at the anode. Both patellar reflexes were abolished.

The cremaster-reflex was studied, and presented some interesting points. The retraction of the testicle, known as the cremaster-reflex, which has been thoroughly discussed by Dr. S. Wier Mitchell,[1] can usually be awakened by irritation of a certain definite region of the thigh extending from the groin nearly to the knee. In young lads, as Dr. Mitchell has shown, this reflex is easily caused by touching or pinching the whole thigh, with the exception of a band of skin which nearly always may be represented as forming the postero-lateral third of the circumference of the thigh. Sometimes, however, the cremaster-reflex region is far less and sometimes far more extensive. It rarely extends below the knees, although, as stated by Dr. Mitchell, it may in the healthy boy include a large part of the calf of the leg. In adults the excitor region is often much restricted, and it may even be absent.

Gentle irritation of the skin of the inner aspect of the right thigh and leg of the patient, as far down as the malleolus, caused very vigorous retraction of the right testicle. Sometimes, but not usually, both testicles were retracted. Similar irritation of the left thigh and leg led to movement of the left testicle, which was marked, but not as vigorous as that exhibited by the right from irritation of the right limb. Now and then, in making this test, the unilateral movement of the left testicle, from irritation of the left thigh and leg, was followed a moment later by an imperfect retraction of the testicle of the opposite side. A similar effect was not produced in any of my examinations by irritation applied to the right limb; neither did excitation of one side cause motion in the other side only.

Dr. Mitchell says: "As a rule, which has infrequent exceptions, irritation of one side produces unilateral movement of the testicle of the same side. There are two forms of violation of this law. In the first, irritation of one thigh causes motion of the testicle of the same side, and also, a moment later, less complete action of the testicle of the opposite side. In the other case, touching or pinching certain parts of the inner and usually of the lower half of the thigh causes reflex cremaster motion on the other side only; while like irritation in other parts higher up give rises only to unilateral activity on the same side."

[1] Journal of Nervous and Mental Disease, October, 1879.

On admission the surface temperature of each calf was 95° F. He usually complained of his legs feeling to him unduly warm.

Late in November transverse white bands were observed across the finger nails about two lines from their posterior limits. The nails were not furrowed, but simply showed white markings. As the nails have slowly grown these lines have remained.

The fingers and fore-arms were hyperæsthetic, but at the same time the patient could not determine with any accuracy as to one or two points on testing him with the æsthesiometer. A similar condition, but more marked, was present in the feet, legs, and as high as the middle of the thighs. The muscles were very sensitive. Applications of hot and cold water were discriminated readily.

I will give the record of pulse, respiration, and temperature, for two weeks from January 9th to 23d.

	Pulse.		Respiration.		Temperature.	
	Morning.	Evening.	Morning.	Evening.	Morning.	Evening.
Jan. 9	—	107	—	23	—	99° F.
Jan. 10	134	140	24	24	98.4° F.	99.2
Jan. 11	134	134	24	24	98.6	98.6
Jan. 12	136	132	24	24	98.8	99.1
Jan. 13	140	128	28	24	98.6	98.8
Jan. 14	140	138	24	28	99.8	98.8
Jan. 15	—	140	—	24	—	98.4
Jan. 16	136	128	24	24	99	98.8
Jan. 17	148	128	24	28	98.8	99.6
Jan. 18	136	124	24	24	99	99.8
Jan. 19	132	116	24	20	98.4	98.6
Jan. 20	124	116	24	24	98.6	98.6
Jan. 21	120	116	24	24	97.8	98.6
Jan. 22	128	120	24	24	98	98.8
Jan. 23	124	136	24	25	99	99.4

The pulse, therefore, during the time of these observations, ranged between 107 and 148, and was nearly always more rapid in the morning than in the evening. The respirations ranged between 20 and 24, standing usually at about 24. The temperature ranged between 97.8° F. and 99.8° F., but commonly was not much either way from the normal.

On admission to the hospital the following treatment was instituted by Dr. Mitchell: Applications of ice and hot water alternately were made three times daily for ten minutes at a time to his arms and legs from the elbows and knees downward. Surface massage with cocoa-nut oil was used once daily. Ice bags were applied to the spine for one to two hours twice daily. One grain of the extract of ergot of the new United States Pharmacopœia was given every two hours, and this was rapidly increased until thirty grains daily were administered. After continuing the use of the ergot for a week the patient's stomach became disordered, and tincture of belladonna in doses of five drops every three hours was substituted. Fifteen grains of chloral were administered occasionally, and sulphate of morphia, at first one twenty-fifth grain, and eventually increased to one sixteenth grain, was ordered to relieve pain when necessary. He was placed on the ordinary full diet of the hospital, with the addition of milk three times daily, and beef tea twice daily.

I made an examination of the patient to note the effects of treatment to-day (February 7th). He has improved steadily day by day. His general strength has increased. He has regained almost entirely the use of the muscles above the knees. He has also much better use of his fore-arms and hands, particularly the latter, being now able to pick up small objects. The "wrist-drop" has improved greatly. He has much less pain, aching, and numbness below the knees; the legs below the knees, however, still remain paralyzed, but are not so completely helpless. He has every appearance of progressing steadily to recovery.

(To be continued.)

REPORT IN MATERIA MEDICA AND PHARMACY.

BY WM. P. BOLLES, M. D.

ACONITE.

THE *Aconitine* literature has been very largely augmented within the past few years, and the subject has been taken up before in these reports, especially with reference to the admirable researches of Messrs. Wright and Luff, in England, upon aconite root.

But the occurrence of a case of accidental poisoning in Winschoten, Holland, caused by the substitution of a *French* nitrate of aconitine for the *German* one intended by the physician, in a dose warranted by the Dutch pharmacopœia for the latter, brought up anew the great difference in strength of the various respectable "aconitines" in the market, and induced the authorities to employ Profs. Plugge and Huisinga to examine several samples and answer the following questions: (1.) What is the difference in their action upon animals? (2.) What is the difference in their action upon man? (3.) What is a poisonous dose of each for animals and man? One of these samples was the fatal mixture with which it is not necessary to concern ourselves, further than to say that it was prepared from "*Aconitin Nitric*," made by *Petit*, in Paris, which itself was the next sample.

This consisted of hard, white crystals, soluble with difficulty in cold water. The authors prepared a solution of one fifth of one per cent., and injected it subcutaneously to prevent loss by vomiting. From the second specimen, "Aconitin Nitric, von E. Merck, a yellowish-brown powder, easily soluble in cold water," they prepared a one per cent. solution as they expected to use larger doses, and administered it in the same way. The third specimen was labeled "Aconitin Nitric von Friedlander, in Berlin," but proved to be made for him by Trommsdorf. Of this they also made a one per cent. solution. It was an agglutinated, hard, gummy mass, of a grayish-white color, very easily soluble in cold water.

Their experiments were made in a similar way with all the different samples, and on the same species of animals, namely, frogs, rabbits, dogs, and pigeons, excepting in the case of the Trommsdorf Aconitine, when lack of material made them unable to experiment upon dogs. The symptoms in all the trials were carefully noted, and described with much detail, but do not differ from the previously recorded signs of aconite poisoning. They observed that the effects of Merck's and Petit's aconitines were the same in kind, but different in intensity, while the action of Friedlander's (Trommsdorf's) appeared to affect the heart less in proportion to its other effects, but the difference was not great.

A table accompanies their paper, in which the doses — proportionate doses per kilogramme — and the result are systematically recorded. Their conclusions are: (1.) "Petit's nitrate of aconitine acts at least *eight times* stronger than Merck's, and is *one hundred and seventy or more times as poisonous as Friedlander's.* (2.) That Merck's Aconitin Nit. is *twenty to thirty times as active as Friedlander's*, and that there is a certain difference in the kind of action, as well as in the intensity, between the two former and the latter. No wonder that they continue, "Since the poisonous strength of the substances sold in the shops under the same name differs so frightfully, the greatest care should be exercised in prescribing aconitine or its salts, since, after the physician has become acquainted with the action of a maximum dose of a certain preparation by experience, there is the dangerous possibility that, by a new purchase, a supply of a *very different strength* may be obtained, the same quantity of which may prove fatal to his patient."

Such was the case of Winschoten, where the dose was within the official limits of the Dutch pharmacopœia.[1]

The article has been reproduced in part in the *Pharmaceutical Journal and Transactions of England* and in *New Remedies*, — the Lamson murder in England serving to keep the subject of aconitine somewhat prominent in the first part of last year.

In addition, there are at least three other important aconitines in the English and American markets of dangerously if not equally varying activities.[2]

First the Aconitia of the British Pharmacopœia, of United States 1870, and the French Codex. A white or yellowish-white amorphous powder, whose authorized dose is from half to one milligramme. Secondly, "Aconitia," made in part or wholly from the Indian or Japanese and other Eastern aconites, and consisting of or containing pseudoaconitia or other alkaloids thought to be more poisonous than aconitia. Thirdly, the "Crystallized Aconitine" of Duquesnel, the most energetic preparation ever used in medicine, whose dose is one fifth to one third of a milligramme.

[Squibb, who has examined this, says it is a nitrate of aconitine twenty per cent. pure.— *Ephemeris.*]

This latter salt has been in use but a short time and that, too, only sparingly, and in the larger cities its high price and great power preventing its general adoption, but it has so far proved to be reasonably uniform in its strength.

In the same line of inquiry is a paper by Messrs. E. L. Cleaver and M. W. Williams before the Pharmaceutical Society (England). They had observed that some specimens of even British aconite extract did not give a tingling sensation to the tongue, and knowing that it was sometimes prepared from *A. paniculatum* in part they procured some authentic extract made from this species as well as some from *A. napellus*, which they examined; that of *A. napellus* was tingling; that of *A. paniculatum* not at all so. Then they examined the fresh herb of *A. paniculatum* without finding any aconitine therein. They did find an alkaloid, however, which was bitter but not pungent, and probably may be picro-aconitine of Groues. (*A. paniculata* was at one time official both in London and Dublin.)

[1] Archiv der Pharmacie, 1882.

[2] See also Dr. Squibb's Ephemeris, not accessible to the reporter until after this report went to the press.

The following extract from an account by Mr Holmes of a visit to an extensive herb garden in Lincolnshire, read before a previous meeting of the same Society, explains the importance of the above examination: "Aconite," — two species of this plant are grown to meet the requirements of buyers: *A. napellus*, yielding an extract which is not perfectly smooth unless made so artificially, while *A. paniculatum* yields one which gives more satisfaction on account of its being more easily worked and presenting a smoother appearance and less resinous character. The former plant flowers in May or June, and the latter from the middle of August to the middle of September, when *A. napellus* has scattered its seeds, and its leaves are turning yellow."

Mr. Muney stated in the same body that probably at least eighty per cent. of the aconite roots now in use were not *aconitum napellus* at all, but were from a different species grown in Japan.

Finally the following paragraph from *New Remedies*, on the different yields of aconitine according to different processes, will serve at least to keep up the complexity of the subject: —

"Mr. Schneider tried different processes to ascertain the comparative yield of alkaloid: The process of the British Pharmacopœia yielded only 0.002 per cent. or one part of alkaloid from fifty thousand parts of aconite. Morton's process gave 0.127 per cent. of a light yellow powder. Hirzel's process yielded 0.0046 per cent. Wittstein's process gave 0.14 per cent. in well-formed, isolated, six-sided tablets. Hottot and Liégois' process yielded 0.296 per cent. of crystals. Duquesnel's process gave 0.239 per cent. of well-developed crystals.

The above note was translated from an article in the *Archiv der Pharmacie*, and contains references to the sources from which the processes are obtained.

It is found, even by the most careful observers, to be no easy problem to judge of the value or even variety of aconite root by simple inspection. The genus Aconitum is a large and widely distributed one, and its species often run very close to each other. More than this, *A. napellus*, the officinal species, grows wild in Europe, Asia, and parts of North America, and either in cultivation or naturally has developed numerous varieties, not all of which contain an appreciable amount of aconitine. De Candolle enumerates twenty-nine, and other observers have placed more than twice as many forms under the specific name *A. napellus*. The roots, too, are very variable, even when of the medicinal species and variety, and of good quality, while those of allied species may resemble them very closely and yet contain little or no aconitine. Mr. E. M. Holmes, in a communication to the British Pharmaceutical Conference, from which the above is in part condensed, after examining (by taste) a number of specimens found that all the inert roots were of later blooming varieties than the typical *A. napellus*. He stated that the German drug was carelessly gathered and ought not to be trusted, and recommends that the British Pharmacopœia require home-grown plants, "*flowering in May and June*," and does not see why any chemist who has a small piece of garden should not grow his own aconite root.

This extreme uncertainty as to the strength of aconitine as prepared by different chemists led the Pharmacopœial Committee to omit it altogether from the officinal list, and prevents many physicians from prescribing a medicine that may be either absolutely inert or fatal in the same dose, according as the druggist may have this or that maker's article in stock. It was suggested in the *Lancet* that the prescriber always write B. P. (British Pharmacopœia) after the name in his prescription, and this course is approved by the editor of the *Pharmaceutical Journal*, but the British Pharmacopœia aconite extract, as actually found in England, appears to be as variable as the aconitines. In the United States we have now no standard aconitine, and for most purposes it may be best to use the Galenical preparations of aconite of the Pharmacopœia (*tincture, extract, fluid extract*, and the new *abstract*; the tincture is a little weaker than before). If, however, it is desired to have the alkaloid it would appear to be safest to order the strongest, — Duquesnel's crystallized,— and make the dose proportionately small. The apothecary, on the other hand, should *never* put up Duquesnel's unless the prescription called especially for it, and then not if the dose did not show that the physician was aware of the intensity of its action.

THE CHEMISTRY OF PODOPHYLLUM.

Dr. V. Podwissotzki has contributed a series of papers upon this subject to the *Pharm. Zeitschrift für Russland*, which have been translated in an abridged form and reprinted in the *American Journal of Pharmacy* by Mr. Fred. B. Power.

According to the author the active constituent of podophyllum, and also of "podophyllin," is a resinous substance, *podophyllotoxin*, consisting of a resinous acid, *picropodophyllinic* acid, which is without action on the animal organism, and an active neutral body, *picropodophyllin*

Podophyllotoxin, which may be regarded as a purified resin of podophyllum, is a very bitter, amorphous white, or slightly yellowish-white, powder. It is permanent, has a slightly acid reaction, is soluble in chloroform, dilute alcohol, and hot water. From the latter it is precipitated very slowly upon cooling, in the form of fine flakes.

If it is neutralized in its aqueous solution, or in solution in diluted alcohol with alkalies it is decomposed, one portion remaining in solution and the other crystallizing out in microscopic needles. The latter is the cathartic principle, picropodophyllin. This can be obtained in colorless, extremely delicate silky crystals, which aggregate upon drying to felt-like, shining, silky masses, soluble in chloroform, ether, and ninety per cent. alcohol, but almost insoluble in more diluted spirit; also soluble in hot fatty oils, from which it crystallizes out upon cooling, and in glacial acetic acid. It is completely insoluble in water, and may be instantly precipitated from alcoholic solutions by its addition. Taste extremely bitter. Although, according to the author, it is the only active principle of podophyllum, its extreme insolubility makes it almost or quite inert, unless given in conditions specially calculated to insure its solution. Thus injected subcutaneously it crystallizes in the tissues, and produces absolutely no effect. It is readily and naturally soluble in picropodophyllinic acid, which is the other component of the podophyllotoxin above mentioned.

This is a resinous acid, obtained in flocculent masses, soluble in alcohol, chloroform, ether, and hot water, from which latter it separates on cooling. It forms neutral salts with alkaline and earthy bases, some of

which are gelatinous in solution, and upon dessication, horn-like. Ammonia finally decomposes it. It is entirely inert, medically speaking, of itself, and would be without importance were it not for the fact that it serves to render the extremely insoluble picropodophyllin capable of being absorbed and consequently active.

The natural compound of these two can be practically isolated from the other ingredients of podophyllin, and is a more uniform and desirable medicine than any other preparation yet made of podophyllum. The dose suggested is from .015 to .03, not exceeding .04. Alkalies should not be given with podophyllotoxin or any preparation of podophyllum, unless as an antidote to an overdose.

Podophylloquersetin is a coloring matter present in podophyllin, whose action is neither emetic nor cathartic, but which appeared in the author's physiological experiments to be the griping element of the crude drug. The separation of this from the above-described substances must be therefore very desirable. *Podophyllinic acid*, fatty substances, and extractive matters of no action upon the body, were also examined. No berberine or other alkaloid was found.

KOLA NUTS.

MM. Heckel and Schlagdenhauffen find that these seeds contain free caffeine in a proportion exceeding that contained in coffee. Besides this they contain theobromine, some fatty matter, much glucose, and a very large proportion of starch. The presence and quantity of these constituents indicate the value these seeds are likely to attain as an article of diet. — *Year Book of Pharmacy.*

OIL OF ANDA-ASSU.

This is obtained from a large Brazilian tree belonging to the order Euphorbiaceæ, the same order in which the croton and castor-oil plants are found. The seeds are about as large as a small plum, have an agreeable nutty flavor, and have long been used in Brazil as a cathartic in doses of two or three. The oil can be obtained in abundance, is used in lamps and by painters. It is a cathartic milder than the crushed seeds (the same is true of castor oil), but efficient in doses of about forty drops. Its taste is at first somewhat nauseating, afterwards sweetish.

Not long ago Dr. Joao Manuel de Castro studied the effects of the oil very closely, and arrived at the following results: —

(1.) Oil of anda-assu may be administered in doses of ten grammes at a time without producing vomiting.

(2.) The purgative effect appears two or three hours after taking the oil.

(3.) There are usually three or four evacuations after the dose.

(4.) No intestinal irritation follows the use of the oil.

(5.) It may be employed in all cases where castor-oil would be used.

(6.) It has the following advantages over castor oil: it produces the same degree of effect with a smaller dose, and it has not the repulsive odor of castor oil.

Other authorities also regard it as a great advantage that it is much more fluid, and therefore does not adhere so much to the palate. Besides, the seed of anda-assu is very abundant in Brazil, and it furnishes a great deal of oil (about fourteen per cent.). In larger doses than ten grains it acts as a drastic cathartic, and may produce griping and vomiting. The fact that it is a rapidly drying oil may prevent its ever taking the universal place of the long used and much abused oil of Ricinus in family medicine closets, as it will be likely to become thick and gummy. It might be conveniently given in capsules.

USTILAGO MAYDIS.

This newly-officinal substance has been in very moderate demand for the past few years as a substitute for ergot. No thoroughly satisfactory analysis has yet been made of it, but one exhibiting a good deal of care and of considerable interest appeared in the Report of the United States Commissioner of Agriculture, 1880, from Mr. Henry B. Parsons. According to his investigations there is a moderate similarity between its ingredients and some of those contained in ergot of rye, but the constituents of both, particularly those of ustilago, will have to be more completely isolated and tested before their identity can be proved. From Mr. Parsons's analysis the following appear to be the most important constituents: (1.) A fatty oil, of an orange-yellow color, peculiar odor, and acrid taste. It is freely soluble in ether, moderately so in alcohol, and is apparently a glycerine ether. It resembles the oil of ergot, but is found in much smaller quantity (4.2 per cent.). (2.) A volatile alkaline substance having a peculiar musty or fish-like odor, not giving the reactions for the alkaloids and in too small quantities for further examination. (3.) An indifferent bland-tasting organic substance, extracted by means of eighty per cent. alcohol, partially soluble in water and easily decomposable. (4.) Five and a half per cent. of what the writer says "resembles the sclerotic acid found by Dragendorff in ergot," — an amorphous red-brown, tasteless powder. In addition to these he enumerates numerous of the common constituents of plants.

BERBERIS AQUIFOLIUM.

The same gentleman has written in the same volume an article upon the above drug, used to some extent in the West, chiefly as a tonic and febrifuge. Its alkaloids are berberine and oxyacanthine, the same as those of common barberry-root, and there is no reason to expect any more from the new than from the older species of berberis. There are also starch, wax, gum, sugar, resin, and a "black substance," but none of these are of therapeutic value. There is no need of any new source of berberine, which is an alkaloid, the bitterness of whose salts is out of proportion to their tonic qualities.

— There was an unpleasant suggestiveness in the inadvertence of a practitioner who signed his own name in the space on a death certificate appropriated to the "cause of death." The registrar said he wished he could be as sure of the correctness of all the diagnoses.

— Dr. Bischoff has published in Bonn, in 1880, a work on the weight of the human brain. His conclusions are based upon 906 autopsies; 559 on men and 347 on women between the ages of fifteen and eighty years. In general his conclusions, both of a positive and negative character, agree with those previously reached by the best observers, as stated in our late editorial article.

Hospital Practice and Clinical Memoranda.

CHILDREN'S HOSPITAL.

CASES IN THE SERVICE OF DR. A. T. CABOT.

REPORTED BY H. S. OTIS, HOUSE PHYSICIAN.

CARIES OF THE ANKLE.

Case I. Julia D., aged five, entered the hospital May 26, 1881.

In July, 1880, she had been treated in the out-patient department for a suppurating gland at the elbow, with enlarged axillary glands.

In January, 1881, the left ankle became swollen, painful, and red. Stiff bandages were applied, but with little benefit, as her mother allowed her to continue walking. She was not seen for some time, and then appeared with the ankle much as before, but with an opening under the internal malleolus.

June 6th Dr. Bradford etherized the girl, enlarged the opening beneath the malleolus, and found that the abscess extended across to the outer side of the ankle. He made a counter-opening just under and posterior to the external malleolus, and passed a seton through just behind the joint.

At first the ankle improved decidedly, and the child was soon sent to the Convalescent Hospital at Wellesley, with a stiff bandage and a simple dressing over the wound. While out there she had the whooping-cough, and when recovering from this went home.

Late in October she again appeared at the hospital, with the ankle more swollen and inflamed than ever.

November 12 she was etherized, and Dr. Cabot made an incision about three inches long on each side of the ankle, and increased the opening on the inner side by a short incision running forwards at right angles with the preceding. The astragalus, which was wholly carious, was removed entire, the lower ends of the tibia and fibula were sawn off, and carious portions of the scaphoid and cuboid bones were removed with the bone-spoon. The wound was packed with marine lint filled with iodoform powder and covered with a Lister dressing, the whole being rendered immovable by an anterior plaster splint.

As the cavity contracted, a simple seton covered with iodoform was passed through the joint, which rapidly closed down upon it till January 8th, when it was removed. The sinuses discharged slightly for some time, and the ankle, if used, became swollen, but this soon subsided under a plaster bandage, and April 1st she was discharged well.

Case II. Eddie W., aged three, entered the hospital September 17, 1881.

No history could be obtained, but the child was pale, emaciated, with sore eyes and mouth, and with one ankle swollen, red, and very tender.

September 24th, Dr. Cabot incised an abscess over the inner side of the ankle, and the joint being found diseased on September 26th, he etherized the child, and with the bone-spoon removed what carious bone could be felt. This made a considerable opening through the tarsus, and making a counter-opening he passed a seton, covered with iodoform, through the joint. A Lister dressing was applied, and an anterior plaster splint for immobility. The sinus rapidly closed down upon the seton, which was removed about the middle of October, and the openings were closed November 5th. The child now acquired whooping-cough, but kept up, and was constantly running about the ward.

Early in December the ankle again became swollen and red, and although put at once into a stiff bandage the sinus reopened. As the little fellow could not be kept quiet, but was constantly up on his feet, the swelling gradually increased till March 16th, when Dr. Langmaid etherized the child, reopened the incisions on the sides of the foot, scraped the bone where it was rough, and put a seton soaked in balsam of Peru through the tarsus.

May 3d the sinus had again closed. A plaster bandage was applied to the ankle. From this time the foot was kept in a stiff bandage till late in September, when, everything seeming solidly healed, he was allowed to use his foot freely without support.

Case III. Maggie M., aged five, entered the hospital October 29, 1881, with an abscess on the inner side of the ankle. This was opened by Dr. Cabot, and the inside thoroughly scraped out with a spoon. No carious bone was found. For a time this seemed to do well, but on her getting up became again aggravated.

March 16th Dr. Langmaid etherized, opened up the old abscess cavity, and scraped out some unhealthy granulation tissue. For a time the foot improved, but then again relapsed.

May 3d she was etherized, and Dr. Cabot made an incision on the inner side of the ankle. The sinus was now found to lead down to carious bone, which was thoroughly scraped out. It could not be determined exactly which bones were affected, but when the carious portion was removed it left a hole directly through the tarsus large enough to admit the fore-finger. An iodoform seton was passed through, and the foot done up in a Lister dressing, with an anterior plaster splint. Everything went along smoothly, and July 26th the seton was finally removed, the wound closing August 1st. A plaster-of-Paris bandage was now applied, and continued till the middle of the autumn, when she had a strong, useful, and movable joint.

In these cases the repair went on very satisfactorily under the use of iodoform, introduced through the joint with setons. The immobility of the joints obtained by the use of plaster splints seemed to do much to hasten the healing.

Case II. illustrates very well the importance of maintaining immobility of these joints for a considerable period after the soft parts are thoroughly healed. Although this child's foot was seemingly well, and free from any pain or swelling, yet when allowed to go about on it, the disease was quickly reawakened. It seems best to continue the support of a stiff bandage for some weeks after the sinuses are closed.

TORTICOLLIS. FORCIBLE CORRECTION.

Minnie N., aged six years, entered the hospital September 16, 1880.

Her parents first noticed a stiffness of the neck three and a half years ago; this gradually increased, and the head was slowly drawn over to the left side. They think that for the past two years it has been stationary in its present position.

During this period the child has had two attacks of partial paralysis.

The present condition is accurately represented in Fig. 1.[1]

The contraction is mostly confined to the posterior muscles of the neck, and the head is drawn down so firmly that the ear and mastoid process rest upon the acromion. The child walks very insecurely, and is much fatigued by any exercise.

FIG. 1.

September 28th Dr. Cabot etherized the child, and by the exercise of a very moderate degree of force brought the head into a straight position.

The skin upon the contracted side had shrunk so during the long malposition that it tore somewhat before the head came straight. With the aid of Dr. Bradford, who assisted in the operation, a plaster bandage was then applied, enveloping the chest and head (as described by M. Delore). This set quickly and maintained the corrected position.

This plaster casque was worn until October 23d, when it was removed, and a wire splint applied similar to one used by Dr. Buckminster Brown at the Samaritan Hospital. The child rapidly gained strength and security in walking.

She was discharged from the hospital January 12, 1881. After this she attended regularly as an outpatient. Although the head kept perfectly in position and the muscles of the neck became soft and flexible, still the child was uncomfortable if the head support was left off. The neck was constantly examined for evidence of caries, but no abnormal appearance could be detected until some time in the spring of 1881, when a slight prominence of the sixth cervical vertebra was noticed. This was never so marked as to be unmistakable evidence of caries; but, taken together with the long-continued weakness of the neck, made the existence of caries a matter of strong probability.

FIG. 2.

January 16, 1883. Her father says that her head is perfectly straight, and that she goes much of the time without the wire support, still, however, using it occasionally. Her general health has improved greatly, and she joins the other children in coasting and such out-of-door sports.

— According to the *Lancet* the number of years that a student has to spend at a medical institution prior to being admitted to examination for a medical degree, in various countries, is as follows: Sweden, ten; Norway, eight; Denmark, six and seven; Belgium, Holland, Italy, and Switzerland, six; Russia, Portugal, Austria, and Hungary five; France, England, and Canada, four; United States, three or two; Spain two.

[1] The cuts, being taken from daguerreotypes, are reversed.

Reports of Societies.

GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FIELD, M. D., SECRETARY.

STATED MEETING, FIRST THURSDAY IN MAY, 1882.

WM. G. WHEELER, M. D., President, in the chair.

SEPTICÆMIA IN WOMEN.

W. S. THOM, M. D., read a carefully prepared paper introductory to the subject of discussion before the Society. This affection has been recognized as a disease — as, indeed, gynæcology has received recognition as a department of medicine — only within recent years. Neither was known forty years ago, at least to the general profession. Septicæmia is a form of blood-poisoning, in which it is supposed the lymphatics play a chief part in the absorption and conveyance of the septic matter. Abscess, so common in pyæmia, rarely occurs in uncomplicated septicæmia. Its main characteristics are insensibility to pain, a degree of stupor, high temperature, very dry tongue, weak, rapid pulse, and a peculiar mawkish sweetness of the breath. It may be discussed as (1) puerperal and (2) non-puerperal. The puerperal state predisposes to septic absorption. Slight laceration at any point in the parturient canal, retention of débris in the uterus, the open mouths of the sinuses at the placental site on occasion of relaxation, the shock to the solar plexus and the cardiac, all combine to favor absorption. If there is decayed matter present the absorbents are ready to take it up.

The disease may be communicated in two principal ways: either from without, as by the fingers or the instruments of the physician, or by auto-inoculation at any point where there may be lesion. Indeed, the system may be inoculated through the sound mucous membrane under conditions of lessened blood-pressure or nervous shock. The mysterious cases in which putrid placenta is retained, with attendant foul lochial discharge, in which still the subject escapes septic absorption, may be explained either because of absence of solution of continuity or because the tears have been first healed to such extent as to be invested with a glaze of granulations unfavorable to absorption.

The reader further gave the notes of a case of septicæmia which had occurred in his own experience. Source of infection obscure, unless it be referred to inefficient nursing and filth of surroundings. Treatment consisted of thorough washing out of the vagina three times a day, which always gave relief, and opium in small doses, often repeated; would now superadd bleeding from the arm, in erect position, till patient fainted. Hesitated to attend his next obstetric case, but Dr. Stevens, who had seen the case just reported in consultation, overcame his scruples. The case came off in seven days, was a difficult primiparous birth, requiring instrumental interference; but patient made a good recovery, as did other puerperal cases following. The reader hereupon detailed the precautions which should be taken by the accoucheur under these circumstances.

Non-puerperal septicæmia may occur after any operation performed upon the pelvic or abdominal organs. Details of an illustrative case in the writer's experience were given. The noteworthy fact was remarked of the very rare occurrence of septicæmia after operation

for cancer of the uterus. This, at least, was true of the reader's observation. This immunity may be attributed to the free use of the actual cautery; but the suspicion was hazarded that the pathological process tends to cut off the absorbents; and so, if contiguous parts are kept clean, there should be little liability to septicæmia.

As to treatment, it is all expressed in efficient disinfection, and for this permanganate of potassa was preferred in solution of strength which shall display the color of port wine; should always be used warm, and sometimes as hot as can be borne. Proof of purity of the parts is afforded by the stream ceasing to return decolorized. For a statement of the anatomical changes caused by septicæmia and pyæmia reference was made to a recent paper published by Dr. E. G. Cutler in the Transactions of the Medico-Legal Society of Massachusetts, vol. i., No. 2.

The following note was communicated from the practice of Dr. Harlow, of Woburn: Two patients delivered in the same day, with one of whom the birth was accomplished before the arrival of the doctor, not so much as a vaginal examination being made. Septicæmia followed in both. The doctor had a case of erysipelas under his care at the time, but whether the poisoning resulted from contagion conveyed by himself is a difficult point to settle. At all events the care of either erysipelas or scarlet fever should preclude contemporaneous attendance on a midwifery case.

The Chair remarked he had recently had three cases of septicæmia under observation, and was made to realize afresh how inadequate are all the resources of the profession in contending against this most malignant disease.

Dr. A. P. Weeks presented condensed memoranda bearing upon the present discussion. Mathews, Duncan, Taylor, etc., believe in the non-identity of the poisons of erysipelas or of scarlatina and of puerperal fever. Macdonald thinks there is no more risk, provided disinfection be employed, in the obstetrician attending upon puerperal fever than in the surgeon's caring for a case of erysipelas. Churchill subscribes to a similar opinion. Robert Bruce had thirty-six cases out of an obstetric clientèle of 3500, covering a period of twenty years, these being variously assigned, as to cause, to variola, adherent placenta, etc., etc. George Hunter reports six cases in seventy-six, of which four were fatal. He believes in the identity of the poisons of puerperal fever and erysipelas; also advises thorough disinfection, inunction of the hands with carbolized oil, etc. The disease followed him even after a period of respite.

Dr. Fritsch, of Halle, subscribes to the opinion, commonly held in Germany, that there is no such thing as puerperal fever in the old sense of specific disease. Several factors may unite to invite the disease, namely, change in the blood, from extensive retrogressive metamorphosis, septic infection at some point of lesion in the parturient canal, etc. Montgomery considers the cervix to be the locus of absorption of septic matter, which he generally found inflamed. Barker admits auto-infection, but does not consider traumatism an essential condition. Has an ingenious theory for the increase of temperature. The disease is rarely ushered in by a chill; pain is generally absent; it is seldom found to be uncomplicated; there will be associated metritis or peritonitis. A remarkable change in the blood is to be observed, which becomes dark and fluid. Does not believe in an attempt to eliminate; enjoins intra-uterine injections, absolute cleanliness, sustaining treatment; gives potass. chlorate, fifteen to twenty grains, every three hours.

Pyæmia is to be distinguished by repeated chills, inflammation of certain joints, which disappears rapidly, and as rapidly passes to other joints. Septicæmia begins early, by third or fourth day, pyæmia later, that is, at the end of a week. Septicæmia presents delirium early; in pyæmia we do not get delirium.

Dr. Atthill records five cases of puerperal fever following upon the admission of a case of erysipelas to the Rotunda Hospital. Dr. Lüke, of Plön, reports puerperal fever in a woman who had erysipelas of the face when delivered. Two more cases, rapid and fatal, followed in the same ward. Trousseau regards puerperal fever as a rare disease, declaring it to be an essential fever; phlebitis and purulent absorption are not all that are necessary to produce it. Epidemic puerperal fever is recognized, but in any case there must be a wound which acts as the determining cause. Purulent infection originates in the veins nearest the seat of lesion. Believes in critical discharges, and that cure may be obtained by means of them.

Dr. Weeks thus summarized his own views: "Pus makes pus, and putridity putridity. Serosity is the element of pus which plays the efficient rôle in absorption. Treatment: quinia, sudorifics, purgatives, support, stimulants." He cited a case of his own, which, upon autopsy, showed no lesions except a slight inflammation of cardiac extremity of stomach. Patient had been to a funeral in New Hampshire; the body, which was exposed, had been too long kept. Was taken with labor pains soon after return, initiated with vomiting of blood, and complicated by a convulsion. Upon this soon supervened a condition marked by all the signs of puerperal septicæmia. In another case autopsy declared various foci of pus, justifying the diagnosis of pyæmia. Here infection was due to the carelessness of the nurse. A case may commence as septicæmia, and afterwards, from the septic condition of the blood, pass into pyæmia.

Dr. Warner recalled a case of mumps in a female patient, forty-seven years of age. She seemed to be recovering, and swelling had nearly disappeared, when she apparently caught cold, and grew very sick. Then saw her in consultation; high fever, dry tongue, coated and spotted. Swelling in the region of the ovaries, and thence extending and involving entire abdominal cavity. Suggested treatment as for septicæmia, namely, quinia in large doses, and iron given freely. There was speedily a favorable response, and remedies were discontinued. Hereupon patient suffered a relapse, with temperature at 106°. Resumed quinia, eight grains every four hours, and iron in large doses; patient soon convalescent.

Dr. Clarke inquired if pain is characteristic of septicæmia.

Reply: rather the opposite. We generally find insensibility to pain, as to all other stimulants, physical and psychical. This confirmed the doctor's experience; had had a number of cases, but they seldom complained of pain.

The Chair suggested if peritonitis complicated the case there would probably be pain. The early training a man has in the profession, he continued, follows him through life. One educated in the prevailing opinion of forty years ago finds it hard to accept all

the refinements introduced by the pathology of to-day. We must believe with Barker, that there is something more than a local cause for the disease under discussion; but what this cause is, our crucibles and our investigations with the microscope fail to discover. We think we owe everything to our quinine or to antiseptics, on account of some past success; we then encounter a hard case and find ourselves powerless, and our vaunted remedies vain. Pathology tells us that typhoid fever is a disease of Peyer's patches; but, for successful treatment, typhoid fever and puerperal fever must be studied clinically. The mild and tractable case of septicæmia, and that which overwhelms from the first, and kills in one or two days, may be caused by the same poison, and present similar morbid anatomy; but, clinically, they are different diseases. Rushton Parker considers puerperal fever allied to putrescent anæmia. He draws a picture of the terrible affection when it attacks immediately after labor, and destroys life within forty-eight hours. Rigors, sweats, suppression of lochia and of lactation, if it had commenced, — constituting, in a word, a living death, masked by continuance of circulation and respiration.

As respects treatment, Dr. Wheeler would hesitate to employ the massive doses of quinia familiar to those who had practiced in the West and South, and perhaps unavoidable there. How is the already intolerant stomach to bear so large quantities of an offensive and irritating remedy? The doctor also pictured the inherent difficulties of this medication in a severe and yet protracted case, wherein is not alone irritability of the stomach, but of the entire alimentary canal. Here we are thrown back, practically, upon the power the patient has, constitutionally, to stand up under disease, and upon antiseptic injections. And for this, the speaker would prefer carbolic acid to the permanganate of potassa.

DR. WARNER replied to the objection raised respecting quinine, that the quinine ought to be given before there was reached such a condition as that portrayed.

DR. MARCY remarked that, while he would give due weight to the criticisms of the Chair, still it must be remembered that the medicine and surgery of the present day are undergoing a marvelous change. Dr. Thom had given the best subdivision; that is septicæmia where the absorption takes place through the lymphatics, and that is pyæmia where the septic matter uses the blood-vessels as its avenue into the system. What is it that is absorbed? We are not fully prepared to say. In many cases it is a germ from without, which rapidly reproduces its kind, once it has gained its place in the interior of the body. It would seem the purpose these germs are designed to subserve, in the economy of Providence, is the rapid destruction of dead matter; but, unfortunately, they may attack and bring mischief to living matter also. Reference was made to Ambrose L. Ranney's monograph on septicæmia and pyæmia as giving an admirable tabulation of the various sources of infection. The speaker proceeded to show, by means of a diagram on the board, the manner in which bacteria begin their work. "Sanitary Science and Surgery," — this was to be the medicine of the twentieth century, in the words of a European correspondent. The labors of Dr. Martin, and those similarly engaged, have already shown how much can be accomplished for prophylaxis and prevention in one department; Charcot's efforts to prevent disease by inoculation of the lower animals, etc., were also instanced.

DR. CLARKE believed that germs, otherwise harmless, if inoculated in a fruitful soil, may produce results which otherwise had not appeared. Thus, in a given case, the bias, the proclivity to septicæmia, is already in the system; nothing further is required but the essential germ to call it forth into active manifestation.

DR. MARTIN declared he belonged to the same class in practice as the Chair, but he was impelled to say that the investigations respecting germs were of the utmost importance. Jenner discovered that if a person passed through a certain disease he is henceforth wholly insusceptible to an epidemic of the same. This was all Jenner said, and he was always careful to say no more than he saw and knew. The profession had gone farther, had reasoned from fact to theory, and had stated as positive fact and as actually observed what properly does not lie outside the domain of supposition. Jenner saw no change in virus at twenty removes, and he hoped there was none. The profession have said there was no change, and have had already to take the back track. Bock's paper is a simple *reductio ad absurdum*. Pasteur's discovery is all-important, but arguments from analogy based upon it will surely carry the profession along the same wild path it has so often traveled before, and end, as upon many other occasions, only in ridicule.

DR. WEEKS cited the opinion of the school who declare that septicæmia does not depend upon bacteria or upon any germ, but is due to chemical change; and if there be organisms present, these are the product of such change, and bear the relation to the disease of effect and not of cause. As respects treatment, the main dependence must be upon thorough washing out of the uterus with antiseptic douches, and upon systematic support by means of quinine, iron, stimulants, etc. The heart is weakened and requires digitalis rather than aconite. If all the diseases of this class depend upon bacteria, and are to be referred to the one poison, we may expect to meet them with the one remedy, namely, carbolic acid. But clinical observation brings us to very different conclusions, and he who would contend successfully against septic diseases must have a broad and varied armamentarium.

The CHAIR introduced to the Society Dr. Chapin, of Lincoln, Neb., formerly of the Massachusetts Medical Society. This gentleman stated that rheumatism would not let him live in Massachusetts, but he had wholly escaped his old enemy by removing to Nebraska. His present home was not a malarious region, and disease requires but little quinine. In the treatment of puerperal fever he chiefly depended upon calomel and opium, and cited several cases with satisfactory results.

VACCINE VIRUS.

An allusion by Dr. Chapin to his difficulty in getting pure and efficient animal virus called up DR. MARTIN, who made startling statements concerning the traffic in that commodity. Material which ought to be thrown away — the débris of crusts, epithelium, etc., — is mixed with glycerine to form a paste. This costs almost nothing, and sells at an immense profit. The virus used at Thomasville Ga., affords a case in point. It cost but a cent per patient, and the public vaccination was intrusted to a "*cancer doctor*." Horrible results followed, the "virus" took so thoroughly that the victims had to go bed; extensive axillary abscesses, in some cases, were but a small part of the mischief.

Such practice, in this and other instances, has brought reproach upon animal virus which it can hardly stand up against. The doctor proceeded earnestly to assert the duties of the profession in this particular: the physician should always get his virus direct from the producer and hold him responsible for results.

CONCLUSIONS OF THE DISCUSSION.

DR. STORER briefly summarized the conclusions of the discussion, placing upon the board a prospectus of the therapeusis of septicæmia; (1.) Cleanliness on the part of the medical attendant. (2.) Cleanliness of the patient. (3.) Cleanliness of the surroundings. As illustrative of the third condition, Dr. Pinkham, of Lynn, had traced a case of septicæmia to a faulty drain. Allusion was made to a recent paper by Dr. Stanberg, U. S. A., Contribution to the Study of Bacteria commonly found on Mucous Membranes of Healthy Persons. Reference was also made to a paper by Dr. Cotting, for which he had been criticised, but which the speaker highly commended, — Disease and Death a Part of the Plan of Creation.

A gentleman present remarked the comparative infrequency of septicæmia in hot weather, when the windows are kept open; believed the disease may be reduced to a minimum by free ventilation.

DR. MARCY rejoined that antiseptic treatment, after all, resolves itself into cleanliness.

VACCINATION DURING PREGNANCY.

DR. MARTIN showed a specimen of a fœtus which had contracted vaccinia in utero from the mother. Illustrates Dr. Meigs's statement that "vaccination during pregnancy is murderous."

W. C. Hunt, M. D., of Newtonville, was elected to active membership, and E. Geron, M. D., of Poughkeepsie, and A. G. Kimball, M. D., of Jackson, Mich., respectively, to corresponding membership. Adjourned.

Recent Literature.

The Systematic Treatment of Nerve Prostration and Hysteria. By W. S. PLAYFAIR, M. D., F. R. C. P. Philadelphia: Henry C. Lea's Son & Co. 1883. 111 pages.

This is a reprint of two papers originally printed in the *Lancet*, and an address to the British Medical Association. The object of the papers is to call attention of English physicians to Dr. Mitchell's method of seclusion, rest, and diet, with massage, etc., in treating certain forms of nervous prostration. He says, in conclusion, that the chief value of this systematic treatment is that it appeals not to one but many influences of a curative character. He is thoroughly convinced that very few cases of hysteria can be preached into health; that very few hysterical women are conscious impostors. He gives full credit to Mitchell for bringing these various agencies into harmonious action for the cure of such patients.

— A writer in the *Medical and Surgical Reporter*, February 17th, claims excellent results in obstinate vomiting of pregnancy from the free administration, as a nutriment, of pop-corn, prepared in the customary manner, and simply salted.

Medical and Surgical Journal.

WATER POLLUTION AND CHEMICAL ANALYSIS.

IN an editorial last week on the report of the Boston Water Commission, in the course of some comments on what might be expected from chemical analyses of water, and the possibility of dangerous contamination by minute quantities of typhoid excrement whose presence could not be detected, we said: "Chemistry seems to have done nearly as much for us already as can be anticipated from it in this direction; . . . it may tell us when there is danger, but cannot assure us of safety."

Since the above was written we have been favored with the supplement to the Eleventh Annual Report of the Local Government Board, containing the Report of the Medical Officer for 1881.[1] Among the valuable papers published therein is a report by Dr. R. Cory on the evidences which chemistry can give as to the presence of certain pollutions of water where such pollutions have been purposely made. His results are extremely apropos to the Boston water supply from Lake Cochituate.

A given amount of water, say a gallon, was intentionally polluted by a given amount of human excremental matter, say a grain, from a healthy or from a typhoidal subject.

As was to be expected, there was to the customary chemical examinations nothing to distinguish typhoid pollution from any other excremental pollution. But from the further analyses the danger of very minute quantities of specific pollution may be forcibly deduced, and the almost inappreciable effect upon the water in parts of albuminoid ammonia is plainly shown. Water purposely polluted with enteric fever stool in the proportion of a grain to the gallon showed a resulting increment of albuminoid ammonia (on an average of experiments) amounting to $\frac{1}{1000}$ (.0010) in the gallon, or what is the same thing to $\frac{14}{1000}$ (.014) of a part per million parts. A particular sample of water purposely contaminated with the filtrate from 3.5 grains of fever stool to the gallon was submitted, along with a specimen of the water not thus contaminated, to Mr. Wanklyn, the chemist, by whom the albuminoid ammonia process has been developed. The increase resulting from this pollution proved to be .020 part per million for the 3.5 grains, or .0057 part per million for each grain of the contaminating stool added to the gallon of water.

[1] London, 1882.

Dr. Buchanan, Medical Officer of Health, makes a practical application of this result, choosing for this purpose the well-known and carefully investigated typhoid epidemic at Caterham, caused by the discharge of the typhoid stools of a workman into the source of the town's water supply. Two hundred attacks of typhoid fever were traced, upon evidence that did not admit of question, to the use throughout a particular fortnight of water that had been pumped from a well, in which a man having enteric fever had been at work, and which he had defiled with his stools. During that fortnight 1,861,000 gallons of water were pumped from the well. If the water for the whole fortnight had contained one grain of excremental matter per gallon, this would have meant that nineteen pounds of excrement had been added to each day's supply of water. Such an amount of excrement was of course not evacuated, nor can one suppose that every gallon of water received precisely the same amount of contaminating matter. But, Dr. Buchanan points out, this serves to show that one grain to the gallon means a very large amount of polluting matter present in water. He goes on to say: "In Dr. Cory's experiments we see a water thus largely befouled by a most dangerous material; and the indications of that befoulment, when expressed by the chemist, in terms of albuminoid ammonia, is the figure .014 part per million parts of the water. Wherefore, it is not permissible to accept the doctrines which have been formulated from the amount of albuminoid ammonia present in an otherwise unknown water." Water yielding from .00 up to .5 parts of albuminoid ammonia, per million, is placed chemically by Messrs. Wanklyn and Chapman, among waters of "extraordinary organic purity;" yet, as Dr. Cory shows, the pollution of a gallon of water by all the soluble and finer particulate matter from 3.5 grains of typhoid stool, is represented in Mr. Wanklyn's own hands, by no greater increment than 0.02 part of albuminoid ammonia per million of water.

From other analyses Dr. Cory finds that equal amounts of albuminoid ammonia may be furnished by extremely different quantities of nitrogenous polluting material, and this is the case even though the polluting substances differ no more *inter se* than one typhoid stool differs from another typhoid stool. When a typhoid stool is compared with a healthy stool obtained under somewhat similar conditions of diet, water polluted with the latter yields to this process (that of Messrs. Wanklyn and Chapman) a larger amount of albuminoid ammonia than water polluted by the same quantity of typhoid stool.

Dr. Buchanan sums up his comments on Dr. Cory's investigations by stating that "the chemist can, in brief, tell us of impurity and hazard, but not of purity and safety. For information about these we must, with the aid of what the chemist has been able to teach us, go outside the laboratory in search of the conditions surrounding water sources and affecting water services."

In other words, the inhabitant of Boston must go to Pegan Brook.

MEDICAL LEGISLATION IN PENNSYLVANIA.

There are two bills now before the Legislature of Pennsylvania that especially interest the profession, — a new anatomy act and an act regulating the admission of persons into insane hospitals and creating a board of supervision. The anatomy act of 1866 had for its objects legalization of dissecting and the prevention of traffic in cadavers; it applied only to the counties of Philadelphia and Allegheny. The present proposed bill requires the appointment of a board of distribution, consisting of professors and teachers of anatomy and operative surgery in the several medical and dental colleges, with representatives from unincorporated schools of anatomy and practical surgery. Public officers having control over unclaimed human bodies shall deliver them to this board, who shall justly apportion them among the several institutions entitled to them by law. The distinctive features of this bill are the creation of a board of distribution, the obligation laid upon public officers to deliver such unclaimed bodies under a penalty of from $100 to $500 for neglect or refusal to do so; and, finally, it is hoped that it will extend over the entire State.

The bill proposed by the very able special commissioners appointed last spring by the Governor to inquire into the treatment of the insane, is one which has excited much comment, and appears to be vigorously opposed by the management of the several insane hospitals. The bill creates a central board, to have supervision over places where insane persons are under treatment, said board to be composed of the Board of Public Charities and three additional members, appointed by the Governor, one of whom shall be a member of the bar, and another a physician, both of ten years' standing and practice. In consultation with the Chief Justice of the Supreme Court and the Attorney-General, the Committee on Lunacy is to act as a licensing board. All pay places where insane patients are treated must take out license under regulations prescribed by this committee for the conduct and control of such establishments. The committee have power to enforce their regulations by suspending the license upon disregard of their rules, and such withdrawal of license lays the offending parties open to a charge of misdemeanor, and any institution of the kind that fails to take out a license commits a misdemeanor. Actions for damages can also be brought against them. Medical records and "case-books" are to be kept in such establishments, with weekly and other periodic records and notes, thus preventing inmates of long standing from being sight of.

An important section of the bill is that which requires one notice of the fact to be mailed to the Committee of Lunacy and another to the Secretary of the Board of Visitors for the county within forty-eight hours after the admission of a patient into any such establishment. The committing physicians must be medical practitioners of five years' practice, and their certificate must be given within a week of the commitment. A medical practitioner, chosen by the patient or his family, and with the sanction of a judge

of a court of record, shall have access to and visit the said "lunatic" at reasonable hours. Boards of Visitors for each county are to be appointed by the Committee of Lunacy to act in conjunction with them. Women may serve on these boards. Every institution in the State that comes under the provision of this law is to be visited once a month by a county visitor or committee member, once in six months by a committee of three, one of whom must be of the Committee of Lunacy, and once a year by a majority of the committee. Any such institution that does not take out a license, or fails to comply with its provisions, is liable to the charge of misdemeanor. The act deals also with the criminal insane, and provides that such persons, when pronounced cured, shall be turned over to a place of custody and not discharged upon the community without legal release. The release of the Committee of Lunacy for all other cured cases is to be equivalent to, and in the absence of release by the superintendents of such asylums, a sufficient discharge.

There are two features in this bill that are supposed to be especially distasteful to insane asylum management: (1) making them responsible to a central board which has the power to confer or revoke a license, without which they may not admit patients, and (2) the power conferred upon this committee to examine records and dismiss patients, and have a supervision over the institution generally. It is believed, however, that this bill, which has been very carefully prepared, will be passed substantially in the form presented, perhaps with one or two minor alterations.

Some individuals are also urging a bill for the regulation of vivisection, and it is probable that a conference will be held with some prominent physicians, and something submitted of this kind at the present session of the Legislature. It is not believed that it will interfere materially with original research, which is just beginning to earn for Philadelphia some new laurels as a medical centre.

AMATEUR THERAPEUTICS.

FEW men are willing to admit that there is any department of human knowledge of which they are quite ignorant. Like Mr. Brooke, in Middlemarch, they have at some time "looked into" every subject that can be mentioned in their hearing; and the positiveness of their opinions reveals no doubt in their own minds that they have seen to the bottom of whatever they have looked into. Few fields are more attractive to "look into" than medicine, and the multiplicity of prescriptions that are offered by friends to any one who is indisposed is a matter of universal observation. Indeed, it is the neighbors and friends of the amateur therapeutist who have to bear the peril of the latter's well-meant but dangerous interest. To take calomel and paregoric out of the hands of the officious old ladies and to direct their whole therapeutic efforts through the channel of sugar of milk is a positive boon to imperiled humanity.

Unfortunately, some of these amateur marksmen (to change the figure) do not fire with blank cartridges, whence come unfortunate results. The Rev. Mr. Timins, vicar of West Malling, England, stands committed for trial on the charge of manslaughter for having caused the death of a young girl, aged seventeen, the daughter of a laboring man in his parish, by administering oil of bitter almonds. The girl was found ill by the vicar, and although medical aid might have been had without difficulty the clergyman fell a victim to what may be called the *cacoëthes præscribendi*, and sent for this drug, which, as he afterwards testified before the coroner, he had frequently used without ill effects. The defense at the inquest was that the death was due to apoplexy, in spite of the fact that an autopsy clearly showed death to have been caused by prussic acid. At the second judicial examination this theory was abandoned, and it was claimed to be simply a case of accidental homicide. Dr. Bristowe testified that Mr. Timins, who was a fellow-student with him, had always showed an interest in the science of medicine, and had been frequently invited by Dr. Bristowe to visit with him the latter's patients in St. Thomas's Hospital. The magistrates, however, decided to let the case go a step further, and committed the clergyman for trial at the Kent Assizes. Of course it is to be expected that the good character and benevolent career of the defendant will prevent an adverse verdict being ultimately rendered, but the authorities seem disposed to make the matter of sufficient prominence to serve as a warning.

Almost coincidently with this event, we learn of a Belgian priest who performed the Cæsarean section under circumstances, however, quite different from those which tempted the English vicar to try his medical skill. A lady was seen by the priest, in his opinion *in articulo mortis*, and who was far advanced in pregnancy. He opened the abdomen and extracted twins, the woman, however, dying during the operation. In the ensuing investigation the priest testified that he made an attempt to find a physician or a midwife before operating, and offered as his defense the urgency of the case and the impossibility of procuring medical aid. The priest has been exonerated in three successive examinations, after each of which the public prosecutor has appealed, and that official now proposes to carry it before the *cour de cassation*, the ultimate tribunal.

If we may judge from the decisions thus far rendered, these two cases may be taken to illustrate the difference between an officious assumption of duties that should be left to others and a reluctant acceptance of a heavy responsibility thrown unavoidably upon one. It is the difference between the physician who draws up a will at the request of a dying patient when legal advice is inaccessible and the man who under no such stress of emergency goes out of his way to usurp legal functions, his bungling discharge of which may cause miserable disaster.

MEDICAL NOTES.

— The relation of quackery to science is exemplified in other fields beside that of medicine. Meteorology, a science of recent development, has ascertained certain laws controlling natural phenomena. The result of the application of these principles in the departments established by the American and English governments has been the attainment of a fair degree of success in predicting weather changes for a few hours in advance. Such bureaus, controlled by educated men and aided by a system of obtaining data which could be gained in no other way than by government agency, possess all that is really known of the art of weather prognosis. Yet these results, meagre as they are in scope, have been of great value to commercial interests. Now, despite the evidence of these men that in the present state of science no valid prediction as to atmospheric changes can be made for more than forty-eight hours in advance, the quacks come to the front and issue their prospectus for the whole year at once. They have no special education, no opportunities for collecting data, no principles of reasoning which they are willing to promulgate, yet they publish the productions of their "natural and intuitional powers" with the utmost boldness. The extravagance of their pretensions gains them a better hearing than is given to the modest claims of the scientific man. The daily papers, almost without exception, throw open their news columns to promulgating the humbug, even if they occasionally discredit it editorially. Of course the prophets know enough to make their predictions in accordance with what is antecedently probable, and their words are sufficiently sibylline to admit of an *ex post facto* reconciliation with almost any occurrences. Even a literal fulfillment would be no evidence whatever of the value of their work, because such fulfillment would be much more explainable on the ground of coincidence than as the result of a method which is so perfectly unscientific.

As with other species of quackery, so here, notoriety and money are the stakes played for by the operators, and harm and loss are the portion of the public. During the past week the prediction by a Canadian soothsayer of a severe storm to occur at this time has paralyzed the entire fishing interest of New England and Canada, owing to the apprehension thus aroused in the always superstitious sailor. One of the wharves in this city was reported as lined with fishing-boats three deep, the men refusing to put to sea till the storm should have come and gone, while a veritable "fish-famine" prevails in Nova Scotia and the cities fed from that centre. In New York alone the damage to shipping interests has been estimated (?) at a million dollars. In all such disturbances of trad of course the mercantile sharks do not fail to make considerable prey. Meantime, wharf proprietors are notifying their customers that they will not be responsible for the safety of property, and the weak-minded and nervous everywhere are prostrated with apprehension, and all because people who ought to know better have stopped to listen to the maunderings of an ignorant pretender. Verily, medicine is not the only field offered the quack, and his work bears the same fruit in every soil.

— In a discussion of the Obstetrical Society of Philadelphia, relative to the effect of the operation for restoring lacerated cervix in causing sterility, Dr. Goodell expressed the opinion that it does have such an influence, mentioning that he has operated in 169 cases and has only known of seven who have since become pregnant. Other speakers, including the reader of the essay under discussion, held a contrary view; one reporting three of his own patients who had been operated upon by Dr. Goodell, and all of whom had since become pregnant.

NEW YORK.

— Several members of the family of a German cabinet maker on First Avenue have recently recovered from trichinosis. The family consists of the husband, his wife, and four children, the oldest of whom is eight years old. On the evening of February 16th they ate some raw ham. The younger children partook principally of the fat, while the lean meat was eaten by the father, mother, and oldest child. The father continued during the next four or five days to eat the ham in sandwiches, which he took with him to his work. On the 19th the mother was taken ill, on the 20th the oldest child, and on the 21st the father, and the physician who was called in found that they were all suffering from the symptoms of trichinosis. Some of the ham was afterwards examined by Dr. Janeway and other competent microscopists, but no trichinæ were found, though they thought that the meat nearer the bone had no doubt contained them in small quantities. It is probable that the fact that the trichinæ were not numerous accounts for the escape of all the patients.

— A young Englishman, a deck hand on a steamer plying between the city and Bedloe's Island, died on March 4th from swallowing a drachm or more of fluid extract of gelseminum, which he took in mistake for fluid extract of gentian. About a year ago he broke his leg, and was treated at the Marine Hospital on the island, and when he became convalescent he was appointed an assistant in the hospital pharmacy. After he became deck hand on the steamer he was still allowed to visit the pharmacy from time to time without the usual physician's permit, as he was supposed to be sufficiently familiar with drugs to avoid making mistakes in regard to them, and it was he himself that poured out the fatal dose.

— On the 1st of March a trifling fire occurred in ward 7 of Bellevue Hospital, which was occupied at the time by sixteen convalescent surgical patients, all of whom were promptly removed. The fire, which originated under the flooring, near one of the steam radiators, was extinguished by means of a patent apparatus kept on the premises, and the services of the fire department were not required.

— The coroner's jury investigating the deaths of the sixteen children killed in the recent panic in the Roman Catholic parochial school on Fourth Street found in their verdict that the building where the dis-

aster occurred was insufficient to accommodate seven hundred children, which was the average attendance in the school, and that the stairways of the building were unsafe. They recommended that frequent and systematic alarm exercises should be had in all schools, and in order to enable the superintendents of different schools to avail themselves of all the experience in the matter, they called the attention of the Board of Education to the expediency of appointing a competent person to superintend the false alarm drills, whose duty it should be to visit, on the request of the principals of either private, parochial, or society schools, their respective institutions, and to instruct the teachers, as well as the pupils, in all the necessary exercises and preparations to prevent panics from whatever cause.

— The Board of Health has just won a case in the Superior Court against the builder of a tenement-house on First Avenue, who filed a plan for the construction of a building five stories high, the specifications of which stated that the lot was twenty-five by one hundred feet, that the size of the proposed house was not to be more than twenty-five by sixty feet, and that no additional structure would be added to the premises. The Board found that the above requirements of the Tenement-House Act were afterwards being violated by the proprietor.

— During the week ending March 3d three cases of small-pox were reported, against one the week previous. On the 5th of March there died of small-pox, at the Riverside Hospital, a man by the name of Fowler, who had claimed to be able to cure the disease by means of mesmerism.

— Mrs. Burnell, a dwarf, upon whom the Cæsarean section had been successfully performed, recently died at the age of twenty-seven. She was born at Richmond, Vermont, and her mother was a woman of ordinary size, while her father was only thirty-nine inches in height. Until within a few days of her death she was on exhibition at Bunnell's Museum with her little boy, who was announced on the bills as "the child that never was born."

— The degree of D. D. S. was conferred upon thirty graduates at the Commencement of the New York College of Dentistry, which was held at Chickering Hall on the 6th of March. On the same evening the fifth annual Commencement of the notorious "United States Medical Colleges" was held at Steinway Hall, when, among the other degrees conferred, was the extraordinary one of "doctor of anthropology," which was graciously bestowed upon Andrew Jackson Davis, the lecturer on spiritualism.

— The Metropolitan Throat Hospital has purchased a new building in West Thirty-Fourth Street, between Eighth and Ninth Avenues.

PHILADELPHIA.

— The Polyclinic will open April 15th. The building at Thirteenth and Locust Streets, leased for its purposes, is being rapidly altered, and the new signs are already attracting attention.

— The commencements of the medical schools are later this year than ever. Jefferson will have its commencement April 2d, Professor DaCosta delivering the valedictory. The University of Pennsylvania will not have its commencement until April 20th.

— A complimentary dinner was recently given by the old medical officers of the Pennsylvania Hospital to the faithful steward, Mr. William G. Malin, who, at the age of seventy-eight years, retires from his duties as superintendent of the department for the sick, having served the hospital continuously for fifty-nine years. The dinner was given February 21st, and was attended by nearly ninety subscribers; a large oil paint-ng of the honored guest was presented to the hospital.

Correspondence.

LETTER FROM BERLIN.

RESECTION OF THE LUNG AS PROPOSED BY DR. BLOCK.

Mr. Editor, — The subject of operating on the heart seems to have excited some interest in America of late, and a recent writer in the Journal (January 25th) in an article on Heart Puncture and Heart Suture, speaks of the experiments of Dr. Block,[1] as pointing the way to a new freedom in this direction. The experiments alluded to consist principally in operations on hearts of rabbits, and are considered as even more important than the researches in regard to heart puncture. The writer of the article regrets that he has been unable to consult Dr. Block's original memoir, but hopes at a future time to do so, as well as to report further investigations on the subject. This article leads me to think that the present communication may not be without interest, although it concerns operations on the lungs rather than on the heart.

In June, 1882, Dr. Block came to the laboratory of Professor Virchow, where I was working at the time, to exhibit specimens of intrathoracic surgery. The specimens shown were principally limited to rabbits, but the operator stated that he had shown that in cows, swine, and dogs, as well as in rabbits, the various lobes of the lungs could be removed quickly, easily, and safely through incisions in the intercostal spaces without cutting ribs or costal cartilages, and was so confident that similar operations could be performed successfully on man, that he declared himself ready to operate at the earliest opportunity. He expressed himself as certain that diseased lobes could be easily and safely removed, and the patient thus given a chance of recovery. The dangers of the operation he regarded so lightly that he remarked that in case of erroneous diagnosis of incipient disease of the apex, no harm would be done if the thorax was opened and the lung found healthy! Besides showing specimens of the lung from which lobes had been removed, and of the heart in which sutures had been taken, he exhibited living and lively animals on which similar operations had been performed without apparent detriment to the general condition. In one of these animals, a rabbit, from which the upper lobe of the left lung had been removed some months previously, he made an incision through the skin in the median line, and exposed the

[1] Amer. Jour. of Med. Sciences, January, 1883, page 276; from Jour. de Méd. de Paris, October 28, 1882; from Gaz. Méd. de Strasbourg, October 1, 1882.

thorax by dissecting away the skin, so as to show the wound in the third intercostal space, and to demonstrate the fact that the remaining lobes of the lung had become expanded, so as to occupy more or less completely the place of the excised one. The thoracic wall was not drawn in, and the lung could be seen through the intercostal space, moving up and down over the region formerly occupied by the excised lobe. The antiseptic precautions were very simple; no one was allowed to touch the animal without disinfected fingers; and the operator, after washing his hands in a two per cent. solution of carbolic acid, rubbed pulverized naphthaline over them. He also rubbed the naphthaline over the region to be operated upon before making the incision, and used the same freely in the wound. After sewing up the incision, the wound was dressed with dry absorbent cotton covered with naphthaline, which was secured by a thin bandage similarly disinfected.

The animal submitted to this inspection with little sign of distress, and was not tied down for the purpose. Dr. Block assured us that the removal of the lung itself was borne equally well, which, he remarked, together with the fact that the whole operation only occupied about three minutes, should disarm the criticism of the anti-vivisectionists, especially when it was considered what a great alleviation of human suffering was anticipated. The doctor assured us that he had been promised opportunities to operate on the human subject, and that he should do so at an early date, with every hope of successful issue. He found it hard, however, to communicate his unbounded enthusiasm and hopefulness to others, and though much interest was shown in the preparations, many doubts were expressed in the first place as to whether the operation would prove so safe and simple in the human subject as in the rabbit, and in the second place as to whether the operation, if successfully performed, would be as efficacious as anticipated in checking the spread of pulmonary disease.

At that time Dr. Block had read an address before the Surgical Congress at Berlin, which he requested me to translate at his dictation for the JOURNAL. He dictated a part, and promised to dictate or forward the remainder soon. After that time I, however, neither saw nor heard from him, and during the summer took the unfinished manuscript with me to Paris. On returning to Berlin recently the news of his unhappy death reached me. It seems that he operated on a young lady, I am told a relative, at her own request. The lungs are said to have been found healthy, but the patient died, according to one report, during the operation; according to another, shortly after. Legal procedures were instituted, but the unfortunate operator took his own life by shooting himself through the head. These events took place several months ago, and are perhaps already known to your readers, as they are here to the laity as well as the profession. The result of the operation showed that the doubts expressed last June were not unfounded, and that the operation so easily performed on rabbits was not necessarily so safe and simple for the human subject as the projector supposed.

The address has been elsewhere reported, but it may not be out of place to give an abstract of that part of it which I translated. The author states that a heretofore insurmountable difficulty in the treatment of pulmonary phthisis has been overcome, and that experimentation has shown that we may enter with impunity the pleural cavity. Upon the fact that the disease begins as a local process, the author bases his hope to cure it by removal of the affected lobe or lobes. He demonstrates the advantage of the lungs over glands and joints as the seat of operation, inasmuch as they consist of independent lobes, which limits the chance of extension of disease after operation, and inasmuch as a vicariously working part makes good the loss with slight inconvenience and no disfigurement. He then details experiments by various observers, showing that both plugging and removal of parts of the lungs have been survived without injury. The advantage of the author's method over all former ones is stated to consist principally in the saving of time and danger by removing the lobe or lobes, previously ligated, through an intercostal space, without cutting ribs or costal cartilages. The operation is stated to have been performed on rabbits in three minutes without loss of blood from the large vessels.

The author considers resection of ribs unnecessary, because the lung even when infiltrated with tuberculous deposit can be removed through an intercostal space, as can be shown on the cadaver, also disadvantageous on account of liability to injury to the lung, and pleurisy, from the action of the edges of the ribs. The time of operation is reduced from forty-five to three minutes by operating between the ribs. He considers drainage unnecessary, as all unhealthy tissue should be removed, and he has never seen inflammation set up by the blood, secretions, or portion of lung behind the ligature.

In case empyema appear there is always time to remove the fluid under the known rules. He considers that drainage, besides interfering with the expansion of the lung, adds to the risk of introduction of inflammatory germs. A series of animals were exhibited operated on at periods varying from six months to two weeks before the Address. The tying down seems to have been the most disagreeable part of the operation, and the animals seem to have been more restless, and the operation less satisfactory when anæsthetics were used than when they were not. The first specimen was a buck rabbit from whom all the lobes of the left lung were removed four months previously, incisions being made in the third and fourth intercostal spaces, the latter for the admission of light. After several hours the animal seemed quite well and lively, springing upon a box, one and one half feet high.

The second specimen was a small dog, the upper and lower lobes of whose left lung had been removed, also about five months previously. Immediately upon its release the animal ate, and after forty-eight hours barked loudly and constantly. Seventeen days after the operation the wound was healed to a granulating line. Twenty-one days after the operation the pleural cavity was again opened, and no pathological appearance was found in the interior. Stretched across the upper part of the pleural cavity were several thin bands of connective tissue. Ten days after the second opening the wound was again healed to a granulating line.

Yours truly, G. L. WALTON.

BERLIN, *February* 19, 1883.

— At a recent meeting of the Obstetrical Society of New York, Dr. Mundé presented a pessary which he had lately cut out of its bed in the vagina seven years after its insertion.

Miscellany.

THE USE OF THE IRON SALTS.

WE find in the *Chemist and Druggist* a quotation from Dr. Prosser James, giving a summary of the position which dialyzed iron is entitled to hold in medicine. He says that the persalts of iron are frequently employed solely on account of their astringency, while the protosalts are occasionally considered as being destitute of this quality. The freshly prepared carbonate is an excellent mild chalybeate, but difficult to keep in an unaltered state, so that preference is given to reduced iron. The scale preparations of iron are held in repute both from the extreme facility of their use and their agreeable taste. When these three forms of iron are inadmissible dialyzed iron may be resorted to with admirable effect. It is a milder chalybeate than the three preceding, and does not produce irritation.

Respecting the therapeutic value of dialyzed iron, of which there has lately been some inclination to doubt, Dr. James says there is no question. By the method now followed of counting blood corpuscles it is found that the taking of dialyzed iron both increases their number and improves their condition. Dr. James gives, as an average dose, twenty to fifty drops, daily, in three doses. Dr. Weir Mitchell, of Philadelphia, gives as much as a drachm at a time. Specimens have appeared in the market which are not only innocent of any acquaintance with a dialyzing membrane, but seem little else than diluted solution of perchloride of iron.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 3, 1883.

Deaths reported 2957 (no report from New Orleans): under five years of age 1080: principal "zymotic" diseases (smallpox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 507, lung diseases 507, consumption 420, diphtheria and croup 171, scarlet fever 71, diarrhœal diseases 44, typhoid fever 44, small-pox 35, whooping-cough 30, measles 27, cerebro-spinal meningitis 27, erysipelas 23, puerperal fever 19, malarial fever 15, typhus fever one. From *typhoid fever*, Philadelphia 13, New York eight, Pittsburg six, Brooklyn and Buffalo three each, Boston, Cincinnati, and District of Columbia two each, Milwaukee, Providence, New Haven, Lowell, and Lynn one each. From *small-pox*, Baltimore 20, Philadelphia six, Pittsburg and Nashville three each, New York, Chicago, and Buffalo one each. From *whooping-cough*, Cincinnati nine, New York and Brooklyn six each, Pittsburg three, Philadelphia two, Baltimore, Nashville, Springfield, Somerville, and Newburyport one each. From *measles*, New York 20, Cincinnati and Holyoke two each, Baltimore, Pittsburg, and Salem one each. From *cerebro-spinal meningitis*, New York and Chicago five each, Cincinnati four, Boston, St. Louis, Pittsburg, and Worcester two each, Baltimore, District of Columbia, Buffalo, Salem, and Haverhill one each. From *erysipelas*, Cincinnati five, New York four, Chicago and Buffalo three each, Philadelphia, Brooklyn, Baltimore, Milwaukee, New Haven, Chelsea, Milford, and Plymouth one each. From *puerperal fever*, Chicago five, Brooklyn three, St. Louis and Baltimore two each, New York, Philadelphia, Boston, District of Columbia, Buffalo, New Haven, and Taunton one each. From *ma-*

larial fevers, New York seven, St. Louis five, Baltimore two' Brooklyn one. From *typhus fever*, Milford one.

Seventy-one cases of small-pox were reported in Baltimore, Pittsburg four, Brooklyn two; diphtheria 28, scarlet fever 20, typhoid fever five, in Boston; scarlet fever 18, and diphtheria 12 in Milwaukee.

In 39 cities and towns of Massachusetts, with an estimated population of 1,136,092 (estimated population of the State 1,922,530), the total death-rate for the week was 19.31 against 19.94 and 16.09, for the previous two weeks.

In the 28 great towns of England and Wales, with an estimated population of 8,620,975, for the week ending February 17th, the death-rate was 21.9. Deaths reported 3611: acute diseases of the respiratory organs (London) 401, whooping-cough 100, scarlet fever 76, fever 74, measles 30, diarrhœa 29, diphtheria 23, small-pox (London and Birmingham three each, Newcastle two, Sunderland one) nine. The death-rates ranged from 15.3 in Birkenhead to 27.5 in Hull; Leicester 18.1; London 20.1; Leeds 22.4; Birmingham 23.9; Sheffield 24.4; Manchester 25.5; Liverpool 27.2. In Edinburgh 22.1; Glasgow 29.5; Dublin 39.1.

For the week ending February 3d, in 171 German cities and towns, with an estimated population of 8,597,081, the death-rate was 27.3. Deaths reported 4511: under five years of age 1965; consumption 709, lung diseases 535, diphtheria and croup 248, diarrhœal diseases 137, scarlet fever 76, typhoid fever 65, whooping-cough 50, measles and röt.eln 33, puerperal fever 23, small-pox (Cannstatt one) one, typhus fever (Hanover one) one. The death-rates ranged from 16.8 in Düsseldorf to 39.2 in Essen; Königsberg 30.8; Breslau 30.8; Munich 32.2; Dresden 24.2; Berlin 27; Leipzig 22.4; Hamburg 33; Cologne 21.7; Frankfort 21; Metz 19.5.

For the week ending February 17th, in the Swiss towns, population 494,390, there were 39 deaths from lung diseases, consumption 35, diarrhœal diseases 15, diphtheria and croup 11, typhoid fever three, scarlet fever two, erysipelas one, small-pox one. The death-rates were, at Geneva 14.4; Zurich 22; Basle 21.4; Berne 32.8.

The meteorological record for the week ending March 3d, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date. February–March, 1883.	Barometer. Daily Mean.	Thermometer. Daily Mean.	Thermometer. Maximum.	Thermometer. Minimum.	Relative Humidity. 7.23 A. M.	Relative Humidity. 3.23 P. M. OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 2, 1883, TO MARCH 9, 1883.

BROWN, HARVEY E., major and surgeon. To be temporarily assigned to duty at Mount Vernon Barracks, Ala., during the absence on leave of Captain T. A. Cunningham, assistant surgeon. Paragraph 2, S. O. 17, Department of the South, March 6, 1883.

CALDWELL, D. G., captain and assistant surgeon. To be relieved from duty at Fort Fred. Steele, Wyo., and will report in person to the commanding officer, Fort Laramie, Wyo., for assignment to duty at that post. S. O. 23, Department of the Platte, February 27, 1883.

PAULDING, H. O., captain and assistant surgeon. The leave of absence granted in S. O. 11, Department of the Platte, January 27, 1883, is extended twenty days. S. O. 23, Military Division of the Missouri, March 2, 1883.

CORRECTION.

MR. EDITOR: In a report of the February meeting of the New York Society of Medical Jurisprudence, published in a recent issue of your journal, I am represented as differing from Dr. Hammond as to the diagnosis of the mental state of the assassin Dubourque. I am at a loss to account for the statement attributed to me that Dubourque was suffering from "general paralysis," for those words were not used by me that evening. I agreed with Dr. Hammond in considering Dubourque to be a "monomaniac with delusions of persecution," and differed from him solely on the question of responsibility, he considering him punishable and I not.

Respectfully, E. C. SPITZKA.

130 EAST FIFTIETH STREET, NEW YORK, *March* 9, 1883.

CORRECTION.

IN the report of the Boston Society for Medical Improvement meeting of February 26th, Dr. Fifield's remarks on Acute Dilatation of the Stomach should read "The case had been at first treated by an irregular."

E. M. BUCKINGHAM, M. D., *Secretary*.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at 19 Boylston Place, on Monday, March 19, 1883, at eight o'clock P. M. Reader, Dr. George Stedman. Subject, (a.), A Case of Laudanum Poisoning in a Child two Days old; Recovery. (b.) Two Cases of Abortion, one presenting Unusual Difficulties in the Ante-Mortem, the other in the Post-Mortem, Diagnosis of the Cause of Death.

C. M. JONES, *Secretary*.

SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION FOR OBSTETRICS AND GYNÆCOLOGY. — There will be a meeting of this Section at 19 Boylston Place, on Wednesday, March 21st, at eight P. M. Dr. T. A. DeBlois will exhibit a new Gynæcological Chair. Dr. C. P. Strong will report a Case of Vomiting late in Pregnancy. Dr. J. W. Farlow will report a Case of Puerperal Convulsions with Induction of Labor.

J. B. SWIFT, *Secretary*.

NEW MEXICO. ITS CLIMATIC ADVANTAGES FOR CONSUMPTIVES.

BY J. HILGARD TYNDALE, M. D., NEW YORK.

When we wish to obtain knowledge in reference to the climate of any section of our country, the meteorological reports of the United States Signal Service are our chief source of information. They are accurate, and are cheerfully and quickly furnished. Meteorological data represent the ever-shifting phenomena in the sea of air surrounding our globe. The "climate" of any region is the embodiment of some stable elements with the above changes superadded, in which embodiment regional geography and local conformation play a prominent part. For this reason it is well to visit and inspect in person the territory, the climate of which it is desired to investigate. Hence my recent trip to New Mexico.

Personal observations with regard to climate include the use of your own powers of observation, the finding of meteorological data kept by physicians or some scientifically inclined individuals, and personal interviews with them. If my material is somewhat scanty, it is because in previous observations I have had to deal with a region of advanced civilization, whereas in New Mexico everything may be said to be new, notwithstanding the evidences of civilization of by-gone ages.

In determining whether and how far the climate of any locality or region of country is suitable for consumptives in the earlier stages, we look for certain elements which reason and experience have shown to exert in combination a beneficial influence upon the general condition and upon the destructive process going on in the lungs of a patient. In my opinion the great desideratum for an ideal climate is an *aseptic atmosphere with considerable altitude for some, and little elevation or sea-level* for the other forms of pulmonary consumption.[1]

AN ASEPTIC ATMOSPHERE.

Germ pathology is now sufficiently far advanced to justify us in accepting the fact of germs (bacteria) being the "ferment of contagion," the organisms which usher in putrefaction in phthisis (I am not satisfied of the specific character of the tubercle bacillus), to cause us to reflect upon the importance of excluding further invasions from without, and to check proliferation within, if not to destroy the already existing breed, and lastly to reason from the premises of the known facts, that lowlands with warmth and moisture are the breeding grounds of septic organisms. Now a truly aseptic atmosphere should not be steadfastly warm or hot, nor loaded with moisture, as the result of evaporation from large bodies of water on the one hand, while the geological substratum of a chosen locality should not admit of subsoil moisture on the other. The importance of subsoil moisture in the development of pulmonary consumption was urged by Dr. Bowditch, of Boston, as early as 1862.[2]

[1] A series of articles giving the opinion of the most prominent pneumatologists of our country on the elements going to make up a suitable climate for consumptives will appear shortly.

[2] Topographical Distribution and Local Origin of Consumption in Massachusetts. By H. I. Bowditch, M. D., of Boston. (Medical Communications of the Massachusetts Medical Society, vol. x., No. 2, 1862.)

The elements of meteorological changes concerning us are humidity, degrees of temperature as to means and equability (diurnal and annual range), barometric pressure, the movements of the air ocean (frequency and velocity of winds), the rainfall, and intensity of sunlight. More or less frequent electric changes, not too frequent winds, and occasional rainfall, are not disturbing factors in the benefit to be gained by consumptives. On the other hand rapid and frequent thermometric changes, a lack of stability of temperature; winds of great velocity and some persistence; and a high relative humidity of some duration — these three elements, when combined for a number of days in any region, are known to be the fruitful source of severe colds, of acute inflammation of the air passages.[3]

Seibert proves from six hundred cases that "if a strong wind accompanies a high, or a rising, or a long-lasting high percentage of humidity, together with an already low or then falling thermometer, then the frequency of pneumonia will be found to be astonishing."

The qualities necessary, then, to constitute an aseptic climate, one which yields no breeding ground for infection, and where the meteorological conditions do not favor acute exacerbations of pulmonary troubles, includes the contrary of the above conditions, namely: —

(1.) Dryness, absence of persistent humidity.

(2.) A cool or moderately warm atmosphere, with a reasonable equability of temperature.

(3.) Shelter from or absence of frequent winds of great velocity.

(4.) A preponderance of clear days over the cloudy ones — in other words, abundance of sunshine, as a natural accompaniment of the other constituents.

ALTITUDE.

Elevation above the sea level may be spoken of as low, medium, and high altitude, ranging say from 1500 to 6000 feet. The latter may be considered as the "line of immunity" in our latitudes. The proper altitude for any given patient should be chiefly determined by the condition of his heart's action. Feeble impulse and rapid action, to begin with a low or moderate altitude (1000 to 2000); moderately weak impulse and rapidity of action, somewhat above normal, to medium altitudes (2500 to 4000 feet); no great variation from normal impulse and action, to high altitudes (4500 feet and over).

With increasing elevation the pressure of the air column is diminished; equably lessened barometric pressure is indicative of a relatively low degree of humidity, and accords with relative dryness found at high altitude.

Of ozone we need not speak here. Its importance and action upon the human organism are undergoing investigation.[4]

Now let us see whether these requirements (which for the want of space I have given only in abstract) are found in New Mexico, and if so, to what extent.

The physical aspect of New Mexico may be briefly summed up as follows: The "Spanish Range" of the Rocky Mountains enters the Territory from the north, and, spreading out into spurs, like the spread fingers

[3] Seibert on Meteorology and Croupous Pneumonia in American Journal Medical Sciences, January, 1882.

[4] See Ozone in Relation to Health and Disease. By Henry Day, M. D. (London.)

of a hand, gives rise to numerous valleys between each spur. The rest of the country is a broad expanse of rolling meadow land, at an elevation varying from 7000 to 6000 feet, sloping off toward the south, and decreasing in elevation down to 3000 feet above sea level. Away from the general range, mountains, valleys, and plains are more or less abruptly intermingled. In the words of Dr. Bizzell, "Rapid transition and great diversity of elevation, containing within its border deep valleys, gorges, and cañons, associated with mountains and elevated and more or less arid plains."

The soil is, of course, a porous one, as is the case throughout the Rocky Mountain region.

Water courses are few and far between. Such creeks as there are, all have their fountain-heads in the regions of eternal snow. The water is clear and supposedly chemically pure, being largely melted snow. Temperature of mountain-stream water about 58° F.

Vegetation is as sparse as it is in Northern Colorado, notwithstanding the more southern latitude. The pine growths of the mountains and mountain plateaux are not sufficiently dense to impregnate the air with terebinthine odors, and thus to be considered as a direct antiseptic agent for continuous inhalation.

In considering in how far we find the elements which we accept as constituting a suitable climate for a majority of consumptives we will begin with

ELEVATION.

Every degree of altitude is represented, from 3000 feet to 8000 feet and over. As 6000 feet represents our "line of immunity," we have use only for altitudes from 1500 feet to 6000 feet. The Atchison, Topeka, and Santa Fé Railroad traverses the Territory from north to south. Along its line have grown up the principal towns and settlements, representing all the above elevations. Traveling through Kansas on the same road it became clear to my mind that coming from the East through that State, and passing through New Mexico from north to south, an invalid is enabled to make a slow journey, beginning at a comparatively low altitude in Kansas, and traveling westward, to gradually ascend, until an elevation of from 6000 to 7000 feet is reached. This may be accomplished without deviating from a straight course westward, and yet to stop at towns of such size as to afford the necessary comforts of life, good food, society, medical attendance, and other things pertaining to civilization. To illustrate this I will give the names of such places, together with their elevations, from east to west on the railroad: —

In Kansas: Topeka, 904 feet; Emporia, 1161 feet; Newton, 1433 feet; Larned, 2015 feet; Kinsley, 2207 feet; Dodge City, 2499 feet; Lakin, 3020 feet.

In Colorado: Las Animas, 3959 feet; La Junta, 4117 feet; Trinidad, 6034 feet.

In New Mexico: Las Vegas, 6452 feet; Santa Fé, 7013 feet.

Beginning in the south, at the junction of the Territory of New Mexico with Old Mexico and the State of Texas, the figures run upwards toward the north to Raton, near the Colorado line, as follows: —

El Paso, 3662 feet; La Mesilla, 3844 feet; Socorro, 4665 feet; Silver City, 5890 feet (not reached by rail); Albuquerque, 5006 feet; Las Vegas, 6452 feet; Raton, 7861 feet.

Our next question relates to the aseptic qualities of the atmosphere, and the elements which render it so at these several elevations.

DRYNESS.

The low relative humidity of the elevated regions of New Mexico are primarily due to far inland position, a fact dwelt upon by Dr. Charles Denison in his work Health Resorts in the Rocky Mountains, and previous papers. The great distance from the Atlantic and Pacific Oceans, as well as the Gulf of Mexico, would preclude any great quantity of moisture from these great sources; and such as it might be, is still further diminished and diluted as it ascends and spreads into space. The other source of more or less constant humidity, subsoil moisture, is naturally absent at such elevation, where the soil is a porous one. Of the rain and snowfall, the tables of the Signal Service as given at their three stations, Santa Fé, La Mesilla, and Silver City, will give information: —

LA MESILLA.

Altitude, 3844 feet; latitude, 32° 17′; longitude, 106° 48′; mean annual barometer, 26.070.

Mean relative humidity from September, 1877, to August, 1882: —

Average mean of five years: 43 per cent. saturation.

Average mean for each month of the year: —

January	51%	July	49%
February	45%	August	50%
March	35%	September	47%
April	31%	October	43%
May	29%	November	42%
June	31%	December	51%

Minimum percentage (greatest dryness) 22.5, May, 1879.

Maximum percentage (highest degree of saturation) 64.5, January, 1879.

SILVER CITY.

Altitude, 5890 feet; latitude, 32° 48′; longitude, 108° 15′.

Mean relative humidity from May, 1878, to December, 1882: —

Average mean of four years: 43 per cent. saturation.

Average mean of each month of the year: —

January	58%	July	52%
February	54%	August	61%
March	42%	September	55%
April	34%	October	54%
May	32%	November	53%
June	34%	December	49%

Minimum percentage (greatest dryness) 18.8, June, 1878.

Maximum percentage (highest degree of saturation) 67.8, August, 1881.

SANTA FÉ.

Altitude, 7013 feet; latitude, 35° 41′; longitude, 106° 10′; mean annual barometer, 23.262.

Mean relative humidity from January, 1872, to December, 1882: —

Average mean of ten years: 45 per cent. saturation.

Average mean of each month of the year: —

January	52%	July	40%
February	54%	August	51%
March	42%	September	43%
April	33%	October	42%
May	29%	November	49%
June	34%	December	55%

Minimum percentage (greatest dryness), 20.0, May, 1873.

Maximum percentage (highest degree of saturation), 71.4, August, 1876.

The most noteworthy fact in connection with the above showing is the very low mean relative humidity in three places, representing the southern, southwestern, and northern portions of the territory. The higher percentages of humidity, occurring in the summer months of July and August, as also in the winter months of December, January, and February, are in accord with the rain and snowfall. On some parts of the coast of California the rainfall is out of all proportion to relative humidity and its percentage, a fact which makes dryness a very doubtful constituent.

Precipitation. Annual Amount (in inches and hundredths).

LA MESILLA.

1878	1879	1880	1881
8.07	7.30	7.10	15.05

SANTA FE.

1873	1874	1875	1876	1877	1878	1879	1880
9.73	19.93	18.97	15.97	13.15	19.52	11.44	9.89

SILVER CITY.

1879	1880	1881
13.77	16.90	30.82

At Fort Union the total rain and snowfall for the year 1881 amounted to 39.48 inches.

In comparing the dryness of these several localities it will be observed that the Mesilla Valley carries off the palm, both as regards relative humidity and precipitation; none of the monthly averages of five years show more than a trifle above half saturation (50 per cent.), while as low an average as 29 per cent. is reached, and in one month 18 per cent., a degree of dryness rarely attained. As proof of this I reproduce the mean relative humidity of various sections of our country: —

New England States, 73 per cent.; Middle Atlantic States, 74 per cent.; South Atlantic States, 79 per cent.; Gulf States, 82 per cent.; Lower Lake Region, 79 per cent.; Upper Lake Region, 70 per cent.; Ohio Valley, Tennessee, and the Northwest, 73 per cent.; Lower Mississippi Valley, 58 per cent.; Denver, Colorado, 42 per cent.

By far the heaviest rainfalls occur in the months of July and August. While there is scarcely any rain during the other months, the rains of midsummer resemble deluges in their character. Very little snow falls except on the highest mountain ranges, from whence it drifts in small part into the valleys and the towns located therein.

Closely allied to the subject of dryness is that of *sunshine*. Of this there is an abundance in New Mexico, the number of perfectly clear days far outnumbering the overcast, cloudy, and rainy ones taken together. I regret that, aside from the reports appended, no records have been kept anywhere of the number of clear days in any one year. The only private data I could stir up were in possession of parties at Las Vegas Hot Springs, and these, I have reason to believe, were not reliable.

Number of Clear, Fair, and Cloudy Days.

LA MESILLA.

Year.	Clear.	Fair.	Cloudy.
1878	238	93	34
1879	252	81	30
1880	191	135	40
1881	161	157	47

SANTA FE.

Year.	Clear.	Fair.	Cloudy.
1877	140	158	51
1878	160	169	36
1879	169	152	33
1880	184	137	45
1882	188	138	39

The year 1881 is omitted, as the report was incomplete.

SILVER CITY.

Year.	Clear.	Fair.	Cloudy.
1879	246	87	34
1880	230	104	32
1881	222	109	32

Average Number of Clear Days in the Summer Months (April to October) and the Winter Months (October to April).

Locality.	Summer.	Winter.	Yearly Average.
La Mesilla.	140	115	255
Santa Fé.	87	104	191
Silver City.	112	122	234

A residence of nearly two years in Colorado justifies me in saying that on "fair" days the sun shines during a goodly portion, if not the greater part of the day. This fact enables me to state that the sun shines during a number of hours almost every day in the year and quite certainly in this proportion: —

La Mesilla, 325 to 333 days; Santa Fé, 298 to 326 days; Silver City, 330 to 335 days.

In the first two above-named places there were no cloudy days for the three consecutive months of June, July, and August, 1879 (a very dry year). At Silver City the *number of cloudy days* for each month in two consecutive years is worth recording: —

Year.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
1880	1	3	0	2	0	0	12	5	3	0	1	5
1881	0	2	0	2	3	2	8	6	4	1	3	2

(To be concluded.)

ACUTE INFANTILE PERITONITIS.[1]

BY T. M. ROTCH, M. D.

PERITONITIS may occur in the infant and child as it does in the adult.[2] As an idiopathic disease it is so rare in infants and children that the cases where it has been studied post mortem have occurred almost exclusively during uterine life, and many of these have presented a history of syphilitic infection. Dr. West[3] in his large experience has seen but one case, an infant seven months old. The septic form of peritonitis is not infrequently met with in the early weeks of life, especially under conditions unfavorable to health, but it is exceedingly rare after the first six weeks. At the Hospice des Enfans Trouvés it was found[4] in six per cent. of the deaths which occurred in one year; there were thirty-nine cases, and though the patients consisted of children of all ages, no case over the age of ten weeks was attacked by it, while thirty-five of the thirty-nine cases were less than two weeks old.

This septic form is supposed to start from the umbilicus,[5] and is a phlebitis umbilicalis, caused either by the diseased umbilicus itself or by puerperal disease in the mother. Infants and children[6] of any age may be attacked by acute peritonitis, following burns, traumatic causes, tuberculosis and infectious diseases, syphilis, the exanthemata, especially scarlet fever, and rheumatism.

Where no cause can be found for the disease we speak of idiopathic or the rheumatic form, opinion being divided as to whether a true idiopathic peritonitis really exists, some maintaining that in the cases reported as such the original lesion has been overlooked, while others consider that an inflammation of the peritonæum may occur of itself, as it does in the pleura, pericardium, etc.

Acute peritonitis in any of the above forms is exceedingly rare between the ages of six weeks and two years. Where some direct cause, such as one of those just enumerated, cannot be found the diagnosis is at times difficult from a want of prominence of some of the symptoms, such as the tympanites, which may be but slightly marked, and it is therefore of importance for the purpose of advancing our knowledge of the differential diagnosis and ætiology of the disease to record those cases where the clinical history has been carefully taken, and where the autopsy has been made by a competent observer, especially as in nurslings the prognosis is so unfavorable, the disease usually proving fatal in a few days.

It is with this view that I have thought it worth while to present to your notice the history of three cases of acute infantile peritonitis.

CASE I. A male infant, two months of age, was seen July 5, 1875, by Dr. Minot, who has kindly allowed me to make use of his notes. Dr. Gordon, of Quincy, took care of the case and performed the autopsy. The infant was healthy and breast fed, the mother a primipara with plenty of milk. For several weeks the infant gained a pound a week. June 28th he began to have dyspeptic symptoms, represented by pain, vomiting, and passages of undigested milk. The symptoms were not urgent, but the infant began to fail in weight and strength, and soon refused to nurse. Various diets were tried, and each was at first eagerly taken but soon rejected by the infant, which was almost moribund when seen by Dr. Minot. Some tenderness of the abdomen was found but no great tympanites, and the vomiting was not a prominent symptom. Cyanosis was marked throughout the attack, and there was some œdema of the hands and feet. Pulse 100; temperature (per rectum) 101° F. There was some suppression of urine. Death took place July 7th. At the autopsy, which was made by Dr. Gordon, the peritonæum was found injected, and there was an effusion of serum and a slight amount of fibrinous exudation; there were no adhesions. The kidneys were much enlarged for an infant of two months, but no disease was detected.

The interesting features of this case, supposing that it was a case of idiopathic peritonitis, was the age, two months, and the want of prominence of the vomiting and tympanites.

CASE II., which is typical of the idiopathic form, occurred under the care of Dr. C. P. Putnam in an infant six months of age at the Infant Asylum, June 17, 1874. The infant was vigorous and well nourished up to the time of the attack, the symptoms of which were continuous vomiting, slight distention of the abdomen, and great tenderness, running a rapid course and terminating fatally in thirty-six hours.

Dr. Fitz, to whom I am indebted for a record of the autopsy, found no lesions of any importance excepting reddening of the peritoneal surface of the intestine and a small quantity of pus in the peritoneal cavity. The case is important from having passed through the hands of an observer like Dr. Fitz without any lesion such as could constitute a source for the peritonitis being found.

CASE III. occurred at the West End Nursery under the care of Dr. Haven, who has allowed me to make use of his careful record of the case.

F. B., a male infant nineteen months old, was first seen at the West End Dispensary by Dr. Haven, March 15, 1882. The infant had a good family history, and weighed 3400 grammes at birth; he was breast fed until the age of six weeks, when he was weaned and put on Mellin's food and cow's milk, and at three months he was receiving mixed table diet. When seen, March 15th, he was well nourished and vigorous, and came to the dispensary to be vaccinated; his weight was 9340 grammes.

April 12th I first saw the infant at the dispensary, he being brought to me for cough and restlessness, which had begun two days previously, and having been up to that time strong and well. His appetite was poor; he was fretful, and his food seemed to distress him; his bowels had not been moved for two days; he was feverish and thirsty. A physical examination showed his flesh to be firm and his color and development good; he had eight teeth (the incisors); his tongue was slightly coated; both tonsils were enlarged and reddened; nothing abnormal was discovered anywhere on palpation or percussion. Auscultation gave coarse mucous and sonorous râles in both backs.

The patient was next seen by Dr. Haven, June 3d, when the report was bad cough for two weeks and poor appetite.

June 10th he was reported as improved, and eating and sleeping better.

[3] West. Diseases of Children.

[4] M. Thore. Archives gén. de Méd., August and September, 1846.

[5] Vogel.

[6] Rehn. Gerhardt. Handb. der Kinderkrank., vol. iv.

June 19th the dejections were green and slimy; the gums were slightly swollen over the canines; restless. Put on milk diet again.

June 23d. Bowels had been moved more frequently for some days; four movements on the previous day, green, slimy, and with a little blood. This state of affairs, with occasional remissions, continued until June 30th, when he was found to be decidedly better, having two movements daily; he still had some cough, and it was found that he lived in a damp basement.

November 14th. He appeared to be well.

November 15th. He vomited twice.

November 16th. He had six movements, green, with blood.

November 19th. He had five movements early in the day, none later; has vomited more or less since the 16th and had cough.

November 20th. Weight 8092 grammes, a loss of 125 grammes since March 15th; appetite poor; face pale; nares acting slightly. Respirations 36; temperature 39.4° C; grunting expiration. Nothing abnormal was found in the chest excepting a few fine râles over right apex. Nothing found in throat. Admitted to nursery. Was quiet during the day, and took milk well. The respiration gradually increased in frequency during the day and the abdomen became distended. At six P. M. temperature 40.3° C.; respirations 74. Abdomen very much distended. One dejection, dark, clayey, green, homogeneous, large, good consistency, offensive. At eight P. M. face pinched and pale; expression anxious; respiration very quick; expiration grunting; abdomen very much distended and tense, tender all over. Percussion showed nothing abnormal. On auscultation respiration rather weaker over left lower back. Did not sleep until three A. M.

November 21st, 1.55 A. M. Temperature 38.6° C. 5.10 A. M. Temperature 38.6° C. Slept till five A. M.; since then restless; abdomen less distended; respirations 74. Nothing abnormal found in lungs; abdomen very tender all over; restless all day. 3.30 P. M. Two dejections during the day; urine scanty. Temperature 41.2° C. 5.20 P. M. A pack at 90° F. was given, in which he was kept until 6.40. At 5.30 the temperature was 40.4° C., and at 6.50 40° C.; respirations 66. 9.55 P. M. Temperature 40.8° C.; respiration 74; more restless. Ten P. M. Pack at 90° F. Eleven P. M. Temperature 40° C. Pupils noticed to be contracted; not contracted before. Died at 11.10 P. M. At instant of death the pupils dilated widely; death very quiet.

November 22d. Autopsy at eleven A. M., by Dr. Whitney.

The loops of intestine were found bound together by a yellow fibrinous exudation and were easily separated; there was no reddening on the surface of the intestine.

The heart was normal, and there was a small amount of fluid in the pericardium.

The lungs were normal, excepting that both lower lobes were dark reddish in color, did not crepitate, and that only a small amount of air could be squeezed from them. Both lower lobes, but especially on the right side, were bound down by a firm fibrous band.

The spleen was enlarged, was covered on the surface with a fibrinous exudation, and the follicles were very much enlarged, distinct, and rather firm.

The kidneys were pale and normal in size.

The liver was covered with flakes of recent lymph, and on section showed the acini red and their periphery yellowish and opaque.

The mesenteric lymph glands were enlarged, varying from the size of a pea to that of a small cherry; the smaller were all translucent on section, and presented only evidences of hyperplasia. A small pocket of the larger glands were found to have become cheesy in the central portions, and in two of these the process had extended through the substance of the gland, broken through its peritoneal covering, and about these points of rupture there was a small zone of reactive inflammation.

Pathological Diagnosis. — *Acute general peritonitis*, which, from an absence of any other source, must be considered to have been caused by the rupture of the above spoken of cheesy degenerated mesenteric glands; *follicular hypertrophy of the spleen, atelectasis of the lungs, chronic fibrinous pleurisy.*

In this case the high temperature and distended, tender abdomen rendered the diagnosis comparatively plain, but the case is doubly rare and important on account of the cause,[1] when we consider that there is seldom any noticeable enlargement of the mesenteric glands under the age of three years, and that these glands seldom soften, but either retrograde or harden from calcification.

ARSENICAL PARALYSIS.[2]

BY CHARLES K. MILLS, M. D.,

Neurologist to the Philadelphia Hospital; Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic and College for Graduates in Medicine.

Having presented this case as fully as possible, I will give in a few words all the information I have been able to obtain as to paralysis and other nervous symptoms shown by the other victims of the poisoning.

Six others altogether, besides our patient, were poisoned. One of these was a little boy, four years old, I. S., to whom a piece of the fatal pie was given as a reward for going on an errand. He died within ten hours, and I have no knowledge of observations as to paralysis or other manifestations of involvement of the nervous system. Probably his death occurred too soon to allow any such observation to be made.

M. S., a sister of the little boy, ate a very little of the pie, and suffered to some extent, but not seriously.

C. H. G., the father of the patient, died November 8th, six days after the ingestion of the arsenic. Besides severe gastro-intestinal symptoms he suffered with pain in his head, back, and limbs, was delirious for some hours, and was almost completely paralyzed.

Mrs. G., mother of the patient, ate a little of the pie November 2d, and had an attack of vomiting. On the 4th she ate a piece of custard, which was also found to contain arsenic, and was attacked with vomiting. A few days later weakness of the legs, with aching and numbness, came on, and the right foot and leg became swollen and inflamed. She gradually recovered.

Mrs. V. ate a mouthful or two of the pie and custard containing the arsenic, and suffered with vomiting, etc., for three days. She has since had paresis and paræsthesia of the legs.

[1] West. The Wasting Diseases of Children.

[2] Concluded from page 248.

Mrs. F., who ate freely of the poisoned food, suffered severely from gastro-intestinal symptoms. She is now under the professional care of Dr. H. N. Umstead, of Yerkes P. O., Montgomery County, Pa., who has courteously written to me about her condition, and the substance of whose communication I will give. Dr. Umstead states that Mrs. F. has been paralyzed from the elbows to the ends of her fingers, and from the knees to the toes. She complained of numbness and coldness in the limbs, and a feeling as if a cord was tied tightly around the waist. She had extreme pain in the paralyzed extremities. She has greatly improved, is riding out daily, can stand without aid, and can even walk a little with assistance. She still has some pain in the hands and in the soles of the feet, but they are not tender to the touch. She has some anæsthesia of the hands and feet, especially of the latter. She begins to enjoy her food, for which at first she had great loathing. Her bowels are moved once, and she urinates twice, daily, but has not quite the natural sensation when the bowel or bladder is evacuated. Dr. Umstead states that Mrs. F. and Mrs. V., whom he also treated, make five cases of arsenical paralysis which have fallen under his care during his professional career.

A careful analysis of the history and symptomatology of the case detailed must compel me to conclude that in well-marked arsenical paralysis we have to deal with a diffused myelitis, decided motor, trophic, and sensory bilateral phenomena being present.

With the assistance of Dr. J. H. Lloyd, one of the staff of the nervous dispensary of the University Hospital, I began the preparation of a résumé of the literature of arsenical paralysis, when the *Journal of Nervous and Mental Disease* for October, 1882 (edited by William J. Morton, M. D., of New York), containing an admirable article on the subject by Prof. E. C. Séguin, came to hand. In this paper the literature of the subject is given with considerable fullness, and to it I would refer those interested.

Beginning with Abano, who flourished as early as the thirteenth century, the authorities quoted or referred to by Professor Séguin are Forestus, Zacchias, Hahnemann, Thilenius, Brodie, Orfila, Christison, Graves, Huss, Leroy d'Étiolles, Imbert-Gourbeyre, Smoler, Jaccoud, Seeligmüller, Popow, Rosenthal, Romberg, Erb, Hammond, and DaCosta.

I will refer here only to the observations of Christison and Popow. Christison describes two classes of cases of arsenical poisoning in which the victims die early without paralysis, and a third class of what he terms subacute cases, with moderate gastro-intestinal inflammation. "In the later stage these cases are apt to show marked nervous symptoms: coma, epileptoid attacks, mania, tetanus, hysterical seizures, partial paralysis resembling lead, paralysis in affecting the extremities; contractures may exist."

In 1881 Popow, of St. Petersburg, published an essay upon the pathological anatomy of arsenical paralysis as produced artificially in animals. The work of Popow was carried on under the guidance of the distinguished neurologist and microscopist, Professor Mierzeyewski, and Séguin considers his essay as in many respects the most important contribution yet made to the subject. Popow concludes that arsenic, even in a few hours after its ingestion, may cause acute central myelitis or acute poliomyelitis; that in chronic cases pathological changes are found in the white as well as in the gray substance, constituting a diffused myelitis; and that the peripheral nerves remain normal, even three months after intoxication. Séguin gives condensed accounts of a few of the cases reported in the literature of the subject, and also reports three cases of his own, all would-be suicides with Paris green. His conclusions are practically the same as those of Popow. According to Séguin, whether the myelitis is strictly arsenical, that is, caused by the direct effect of the arsenic on the tissue of the spinal cord, or whether it is produced (as are many forms of myelitis) by the irritation of peripheral nerves (cutaneous, intestinal, and gastric nerve-endings), is a question which cannot at present be definitely solved, but which presents an interesting field for future research and speculation.

Dr. Lloyd has collected the following references to authorities and cases in addition to those cited by Séguin: —

Beck [1] gives three classes or varieties of arsenical poisoning. In the third variety there is first the inflammatory action, then, when this recedes, comes the second stage, that of nervous involvement. The nervous symptoms vary "from coma to an imperfect palsy of the arms and legs, and between these extremes are observed epileptic fits or tetanus."

Taylor [2] gives several cases where the symptoms of *narcotism* (or general paralysis of the nervous system) were marked.

A man swallowed, by accident, some arsenic early in the morning. He went to work for several hours afterwards, and was then gradually observed to sink into a drowsy state, and died that night with no complaint of pain.

A child, aged two and one half years, died *narcotized* two hours after taking the poison.

Wharton and Stillé [3] make mere mention of palsy as a symptom which is apt to occur late in the case.

Taylor [4] speaks of local paralyses, preceded by numbness or tingling in the fingers and toes, as common consequences of chronic arsenical poisoning.

According to Stillé [5] arsenical paralysis most frequently affects the lower limbs first, extending gradually to the arms, but it is more permanent in the legs, continuing for months or even years. It is accompanied with cramps, spasmodic movements, numbness, and formication. The cutaneous sensibility is impaired, and the patient generally complains of coldness in the parts affected.

H. C. Wood [6] speaks of paralysis which follows nonfatal cases, and affects preferably the lower extremities, commencing and remaining longest in them; does not select the exterior muscles, and is almost always accompanied by anæsthesia, or at least by numbness and formication, and by coldness of the extremities. He quotes experiments on frogs, mostly from Sklarek.

Ringer [8] refers to his experiments on frogs. He found paralysis of sensation, reflex action, and voluntary motion. He believes that the paralyzing action is exerted on the cord first, then on the nerves, and

last on the muscles. The difference may be noted between Ringer and Séguin that Ringer does not refer all pathological changes to the cord. He regards the arsenic as a "protoplasmic poison," affecting all tissues. He says that frogs are sometimes only apparently paralyzed, that is, sensation is lost, and hence there is no response to external irritants, but if laid on their back they turn themselves over.

The Index Catalogue of the Surgeon-General's Office gives the titles of forty-three books on the Physiological and Therapeutic Effects of Arsenic, but nothing special on its paralyzing effects.

Gibb[1] records the case of a lady who had taken arsenic, mostly Fowler's solution, for many years for a skin affection. She had attacks of acute neuralgia in groins, shoulders, and sides. These pains were considered due to arsenic by Sir James Clark, Dr. Robert Lee, and Dr. Copland, who all saw the case. Afterwards she lost all power over her lower limbs, which felt numb, although sensibility remained perfect. This retention of sensibility is at variance with other observers and experimenters. After death the abdominal and thoracic glands were found enlarged, and traces of arsenic were found in liver and lumbar vertebræ, although the drug had not been taken for more than seven months before death.

Colton[2] mentions the case of a patient who swallowed, accidentally, some arsenic, and was admitted to the hospital under Dr. Colton's care. The primary effects of the poison had been successfully combated with proper remedies. Seven days afterwards, when feeling quite well, he was attacked with violent cramps in index finger of right hand, spreading to other fingers, then to other hand, and finally to the feet. The pain in hands subsided as the feet became affected. The cramps lasted thirty minutes. He then fell into sound sleep, it being night, but in the morning he found to his surprise that he had lost the use of the affected parts. This paralysis had continued unchanged for five months. There was also a feeling of heat and numbness in the arms from the fingers to a little below the elbows, and in the legs from the toes to a little below the knees. Lancinating pains also occurred in those parts daily from five P. M. to midnight. He improved slowly under the use of quinia, strychnia, and electricity.

McCready[3] relates that a woman rubbed white arsenic mixed with gin on the head of her child suffering with favus. The child died in less than forty-eight hours with its legs completely paralyzed.

Maclagan[4] visited Styria in the year 1864, and had personal interviews with two "arsenikophagites," one of whom ate in his presence nearly five grains of arsenious acid, and the other nearly six grains. The urine of both of these men was carefully bottled and taken back to Great Britain, where a chemical examination revealed arsenic. The physiological effects on these toxicophagi are described as being only tonic and stimulant, especially improving the wind and increasing sexual desire. Maclagan's evidence is strong, yet perhaps not such as would be received in a court of justice, as the men were not kept continuously under observation. The point of chief interest is that he says nothing about paraplegia or any acute or chronic poisoning symptoms among these arsenic eaters.

Dr. Lloyd has called my attention to a case, not before reported, of suicide with arsenic, which happened some years ago in Bucks County, and was under the care of late Dr. Hendrie. Anæsthesia and paralysis were so marked that the man declared that his legs were cut off, and died in that belief.

A CASE OF HEPATIC ABSCESS.

BY ISAAC F. GALLOUPE, M. D., LYNN, MASS.

A CASE in which two large abscesses occurred in the same liver, each finding vent by a natural but not the same passage, and ending in recovery, may not be unique, yet it is sufficiently rare, especially in this climate, to be worthy of record for the use of the future gatherer of statistics.

In this report I have purposely omitted all minor details, as they possess no special interest, and their relation would be tedious to the reader.

The patient was a widow, fifty years of age, who had never been out of New England. In the spring of 1872 she had an attack of hepatitis, from which she apparently recovered. In the fall of the same year she had an attack of "bilious colic," that nothing but a hypodermic injection of morphia would relieve. The conjunctivæ and skin became intensely yellow, — I may say without exaggeration that they were the color of gold; the urine and sweat were loaded with bile pigment, the bowels constipated, the discharges clay-colored, the intestines distended with gas, and the whole cutaneous surface affected with intense pruritus. These symptoms shortly diminished in intensity, except the discoloration of the skin, which, instead of fading out, became of a brown color, and the skin has gradually grown darker, until it is so black that were it not for her Caucasian features, the woman would readily be mistaken for a dark mulatto.

Other similar attacks occurred at irregular intervals, averaging one every three or four months until May, 1880, when one of unusual severity took place, accompanied by vomiting, dyspnœa, tenderness and distention of the whole abdomen, constipation, rapid and feeble pulse, and cadaveric countenance. After these symptoms had continued two weeks, and she had come to death's door, a large fluctuating tumor appeared at the epigastrium, and gradually became more prominent until evacuation through the abdominal walls was indicated, and aspiration was decided upon. Suddenly, while the patient was in a semi-comatose condition, pus began to pour from the rectum in great quantity and with great force; at least two quarts of bile-tinged pus were discharged within five minutes, and there was a constant but gradually diminishing flow for three or four days. The abscess had evidently opened into the colon. There was no vomiting after the evacuation of pus per anum began, but the tumor suddenly disappeared, and the condition of the patient improved daily for three weeks, when there was a sudden and profuse discharge of pus from the mouth through the bronchi, which nearly strangled the patient. This was followed by an incessant coughing that nearly destroyed life by fatiguing the patient and preventing sleep. At length

opiates were given in sufficient quantity to procure sleep, but the expectoration of pus continued four or five days before it ceased entirely. All the friends present agreed in the opinion that the quantity thus discharged through the bronchi was not less than four quarts.

The patient rapidly recovered a fair degree of health, which she has enjoyed to the present time, — a period of two years and eight months. The yellowness of the conjunctivæ and the brown color of the skin, however, have not diminished.

No calculi have been seen.

RECENT PROGRESS IN THE THEORY AND PRACTICE OF MEDICINE.

BY GEORGE B. SHATTUCK, M. D.

"LAVAGE ET GAVAGE." STOMACH WASHING AND STUFFING. ARTIFICIAL ALIMENTATION.

WITH the two words "lavage" and "gavage" the French medical slang of the day expresses the system of irrigation of the stomach and forced feeding, which Messrs. Debove and Dujardin-Beaumetz, among contemporary hospital practitioners, have done so much to reintroduce, to develop, and popularize. Since the introduction of the stomach pump in the early years of this century the process of washing the stomach has been practiced occasionally for various purposes, and especially in cases of poisoning, but it is mainly to Kussmaul and his first publication on the subject in 1867 [1] that a systematic application of stomach washing to diseased conditions, to digestive derangements, and particularly to dilatation of the organ, is due. Kussmaul used the stomach pump with its rigid tube.

In order to do away with the pump and avoid the possibility of injuries to the mucous membrane of the stomach attendant upon its use, various experimenters, and, among others, Somerville in this country, suggested the application of the siphon process. The next step was the substitution by Faucher, in France, of a soft, flexible rubber tube, which the patient could swallow himself. To this M. Debove added a somewhat flexible stylet, finding the introduction of the flexible tube facilitated thereby. With such a tube, four to five feet long, and of suitable diameter, a glass funnel, a pail, and additional tubing if desired, one has all the necessary apparatus for washing out the stomach and administering artificial alimentation.

The process of washing alone or of washing and feeding has been tried now in a large number of cases in Paris, both in hospital and private practice, especially by Messrs. Debove and Dujardin-Beaumetz, within the last two years, and is very favorably reported on by them and others in many cases of exhaustion from wasting diseases, as phthisis, of gastric derangement as from chronic alcoholism, of dilatation, and even of ulcer and cancer of the stomach when employed with due precaution and in proper stages.

For washing out the stomach tepid water simply or various alkaline solutions are used, as bicarbonate of soda in water, half a drachm to the quart, or sulphate of soda in water, a drachm and a half to the quart. For disinfection, where sarcinæ or an offensive odor are present, weak solutions of resorcin or boracic acid are recommended, and as a local calmative bismuth in water.

For alimentation M. Debove began at first to use minced meat simply or raw eggs in milk, but it was found impossible to mince meat fine enough for very rapid and easy digestion, and, moreover, the tube was liable to become stopped either in its course or at its extremity. To obviate these difficulties the minced meat is now dessicated by being subjected to a temperature gradually elevated to 120° C., and then reduced to a very fine powder. Six pounds of meat make only one pound of this meat powder. Where economy is an object the powder may be made, as for hospital use in Paris, from horse flesh; Debove has also used liver for this purpose, but it is too liable to changes. The powder may be administered incorporated in water, or milk, or bouillon, with eggs or without, but care should be taken to make an even mixture. Similar powders of lentils or of bread are administered when the nitrogenous diet is not indicated.

As to the kind and quantity of nourishment each case naturally offers its own peculiarities, and in general the maximum quantity of ingesta must be approached gradually. It is found that a quart of these food mixtures is as large an amount as the average stomach will support comfortably at one time. It is not unusual to wash out the stomach three times a day, and after each washing to administer a quart mixture of milk or bouillon with two hundred grammes of meat powder and three or four eggs. Two hundred grammes are about six and a half ounces, and that amount of powdered meat represents more than two pounds of the untreated article. Under this treatment many patients previously unable to take or digest food are said to thrive and gain rapidly in weight and strength. When the stomach shows signs of being oppressed by its burden it is considered good practice to insert the tube and withdraw a portion.

It is found after a few days that patients can perform the whole operation of washing out and feeding for themselves.

THE RELATIONS OF MICRO-ORGANISMS TO INFECTIVE DISEASES.

Prof. Ernst Ziegler, of Tübingen, in a text-book [2] just published, gives a judicious and intelligent résumé with a full bibliography of what is at present known about parasitic schizo-mycetes or bacteria,[3] and their relations to infective diseases. As Professor Ziegler is neither a partisan nor an enthusiast, we are glad to give the substance of a few of the more important passages from his chapter on this subject: —

[1] Schmidt's Jahrbüch., vol. cxxxvi., p. 386.

[2] A Text-Book of Pathological Anatomy and Pathogenesis, by Ernst Ziegler, Professor of Pathological Anatomy, University of Tübingen. Translated and edited for English students by Donald Macalister, M. A. M. B. London: Macmillan & Co. 1883.

[3] The word bacteria is used in the broad sense to represent the Schizomycetes or fissuring members of the protophytes or low form of vegetable micro-organisms.

The strongest point of evidence in favor of the organic nature of the poisons that produce the infective diseases is their power of unlimited reproduction and multiplication. Infection transmitted through the medium of the air (which certainly takes place), is scarcely to be explained if it be not that the air has had corpuscular particles suspended in it. Chemically active gases would very quickly become diffused through the atmosphere, and at short distances would become attenuated beyond the power of doing mischief. The small quantity of infective matter required to set up the corresponding disease is another point in the evidence. The extraordinary potency of the matter can only be explained by the theory that the virus is reproduced and multiplied within the organism.

The researches of the last ten years have shown that there are, in addition to a multitude of non-pathogenous bacteria which beset the healthy organism, pathogenous bacterial fungi, which are able, by virtue of their specific properties, to affect the animal body and generate disease in it. On the other hand we find such fungi in the blood and tissues of persons affected with infective disease. We must admit beforehand that the available observations on this head have not the extent or exactness which we could desire. Only in the case of a few diseases is the bacterial nature of the virus demonstrated by indefeasible histological and experimental investigation. Such diseases are septicæmia, erysipelas, splenic fever, and tuberculosis. In others, and the greater number of the diseases now referred by many to the action of micro-organisms (such as typhoid, relapsing fever, diphtheria, the exanthemata, croupous pneumonia, acute atrophy of the liver, cholera, etc.), the presence of bacteria has been demonstrated in single, or, as with relapsing fever, in a very large number of cases,[1] but their causal relation to the disease has not been proved, either because the disease itself has not been typically reproduced by inoculation or because the inoculation virus has not been shown to be the result of an absolutely pure culture.[2]

In many other diseases neither the presence of micro-organisms nor their causal relation to the disease have been hitherto made out. As the question at present stands, then, we can only say, that among the infective diseases there are certainly some which are due to the invasion of a microphyte, and that it is highly probable that others have a like origin. Two factors, a proper microphyte and a proper medium, are necessary to produce a given result. If the microparasitic theory be correct, we must admit that some of the pathogenous bacteria usually develop and multiply without the body, while others usually do so within it.

The defective state of our knowledge makes it impossible at present to give a definite answer to the question of the mutability of bacteria. Koch's culture-experiments lead him to the conclusion that the pathogenous like the non-pathogenous bacteria do not alter in their properties. After cultivation for many generations the same developmental forms continually recur, and their physiological properties remain in every respect the same. A change from time to time in the nutrient medium produces no recognizable differences. Koch does not dispute that mutability of species is possible among bacteria, but holds that no adequate evidence has yet been brought to prove it.

[1] Reporter.
[2] Reporter.

Among clinical observers some even go so far as to assert that mutability of species is impossible.

Naegele, Davaine, Buchner, and Wernich, have argued from their experiments against Koch's position. The experiments of Koch and his associates do not as yet prove that the properties of bacteria examined by them are perfectly constant; they only show that the morphological and physiological qualities possessed by a bacterium at a given time are retained by it with some tenacity, even when a certain amount of variation takes place in its environment. Some of the conclusions of their opponents, as the transformation of the hay bacillus (bacillus subtilis) into the splenic fever bacillus, have been discredited, and their researches show at the most no more than that one or other of the properties possessed by a biological species of micro-organism may be brought into prominence by proper modifications of external conditions, but do not indicate that one species may be transformed into another.

The mutability capable of being manifested by a given bacterium may, in the present state of the investigation, be said to have definite limits. It cannot in any period of time within the extent of our observation acquire properties different from any of those possessed by the species to which it belongs. As to the extent of the cycle of varieties through which any one of the known bacteria may pass, we know, indeed, but little. It is possible that the properties of many of them admit of only the slightest variations from those with which we are acquainted. It is, moreover, probable that many of the varieties known to us constitute true biological species.

We may provisionally conclude that the transformation of innocuous into noxious bacteria can occur, if at all, but rarely, and under special conditions. In other words, the pathogenous micro-organisms, even if they do not represent biological species, are wont to maintain the pathogenous form for long periods of time.

We are not yet in a position to formulate a theory of *bacterial action* that will apply to all cases. In general it may be said that pathogenous bacteria withdraw their nourishment from the tissues among which they are growing and multiplying, and from these only; they interfere with the nutritive activity of the tissue cells, and oppose a foreign fermentive action and ferment products to those of the tissue cells.

The effect of withdrawal of nourishment only becomes dangerous to life when bacteria multiply within the circulating blood and withdraw indispensable oxygen. The struggle between the catalytic action of the tissue cells and of the bacteria is carried on to the triumph and destruction of one and the other of the opposing agents. In the investigations of Toussaint, Pasteur, and Koch with regard to the attenuated inoculation virus of splenic fever, it is well known that carbolic acid, oxygen, and temperature all influence the activity of this bacillus, and Koch sustains the belief that the products of extreme activity of the bacillus, favored by oxygen and a not too elevated temperature, bring about in turn an attenuation and destruction of the parasite. In these well-established experiments and theories suggested by them we find a clew to self-limited diseases, to the influence of cold, of antipyretics, and antiseptics, whether hyperpyrexia be the result of changes in the tissue cells or direct action of the nerve centres.[3]

[3] Reporter.

For the processes of investigation now followed by Koch and his school, and the guarantees which these offer for reasonable theorizing, one may consult with advantage the admirable Opening Cartwright Lecture, by Dr. W. T. Belfield,[1] and Koch's pamphlet addressed to Pasteur, of which a brief abstract was given in this journal.[2]

MALIGNANT ŒDEMA IN TYPHOID FEVER.

"Koch has occasionally found in putrefying matters a bacillus which produces in animals an affection resembling splenic fever. He describes the affection as malignant œdema, and the bacillus as 'bacillus œdematis.' It is fatal to mice and guinea-pigs. The site of inoculation becomes œdematous, and is beset with bacilli. These spread into the serous cavities, but, except in mice, the blood remains free from them. . . . The bacilli are somewhat narrower than splenic fever bacilli. It is possible that the bacilli found in certain affections due to poisonous meat are œdema bacilli." (Ziegler.) This affection and bacillus has been supposed to be confined to animals. Messrs. Brieger and Ehrlich,[3] however, think they found this disease causing a fatal termination in two cases of typhoid fever following subcutaneous injections of tincture of musk on account of threatened collapse. Œdema spread from the points of injection over the upper and lower leg, death resulting in three or four days. Offensive gas and bloody serum found exit upon incision of the parts. These observers found, they think, the characteristic bacillus in the liquid, and produced the characteristic disease by injecting this liquid into guinea-pigs. This bacillus differs from that of splenic fever, it is said, in being somewhat narrower, a slender margin on which to base the first appearance in man of an affection hitherto rather ill defined even in animals, especially as the methods employed would seem to lay the reporters open to some of Koch's reproaches to Pasteur. We shall not at present add "malignant œdema" to the dreaded complications of typhoid fever, even after the subcutaneous injection of tincture of musk, should we ever be tempted to use that form of stimulant.

C. M. JONES, SECRETARY.

DECEMBER 18, 1882. DR. DENNY presided.

A TYPHOID PATIENT ARRESTED FOR SUPPOSED DRUNKENNESS.

DR. MCCULLOM spoke briefly of a case now under his charge. The patient was found wandering about in a delirious, stupid condition, and was arrested for supposed drunkenness; but though he had been drinking, and, as subsequent inquiry showed, drinking habitually, leaving his bed to get to the saloon, the stupor and the delirium did not arise from the liquor taken, but from disease. He has now the stupor, the delirium, the retention of urine, and other symptoms which make the diagnosis of typhoid fever unmistakable. Such an error might occur without fault, and although the patient was transported about, and not at the outset put under medical supervision, no blame could be attached to any one in connection with the case.

DR. DRAPER spoke of the frequency with which one sees in English journals the heading "Drunk or dying," and contrasted the recklessness or the stupidity so often displayed there with the greater care taken in this country. In England apoplexy is found to exist quite often in cases of supposed drunkenness, but such a condition occurs here very rarely. The police do not take risks, but if a case does not pursue the course of an ordinary drunken fit medical aid is speedily summoned, and every precaution taken. During the last six years not more than two cases have been recorded where a post-mortem examination showed apoplexy to have been mistaken for drunkenness.

DR. MCCULLOM said he had known two cases of typhoid previous to this one where the patients had been arrested for alleged drunkenness. In both these the arrests were made at the request of friends because the patients were believed to have delirium tremens, and were uncontrollable.

DR. ROTCH read the regular paper on

ACUTE INFANTILE PERITONITIS, INCLUDING A CASE OF PERITONITIS FOLLOWING CHEESY DEGENERATION OF THE MESENTERIC GLANDS, OCCURRING IN AN INFANT EIGHTEEN MONTHS OLD.[4]

DR. BOWDITCH said that notwithstanding his experience in autopsies had been very large, he had never seen such a case as that recorded by the reader. He wished to know in regard to the frequency of such cases. There seemed to have been present all the symptoms and clinical appearances of general tubercular disease. Was a thorough examination of the lungs made with reference to the existence of tubercular trouble in that organ?

DR. ROTCH replied that no other trouble was present, and no other cause for the disease than that assigned could be found. He had known of no other case where the disease had been ascribed to this cause, and in this respect his own case was unique in literature.

DR. INGALLS asked for more definite information in regard to the facial expression in these cases.

DR. C. P. PUTNAM said in regard to his own case that in looking at it after the autopsy, and comparing the symptoms, it might seem that the diagnosis should have been made; but each individual symptom may occur in other diseases, nor is the grouping characteristic. The face had simply the usual expression of abdominal disease, the same as in enteritis. It was drawn and pinched, distressed. Diarrhœa also may occur in this disease, but constipation is more common.

DR. ROTCH spoke of the great rarity of the disease in infants. Most of the recorded cases of peritonitis in children are from seven or eight years and upwards, and each case should be reported as fully as possible in the hope that we may eventually get some signs or group of signs which will enable us to make an early diagnosis.

DR. WHITNEY said that he was very skeptical as to the occurrence of cases of acute purulent peritonitis, such as that described by the reader, without any assignable cause. When he was unable to find the cause post mortem he was more inclined to believe that he himself had overlooked it than that it did not exist, especially since our field of causation was so much

[1] New York Medical Record, February 24, 1883.
[2] January 18, 1883, page 64.
[3] Berliner klin. Wochschr., No. 44, 1882. Centralblatt. für klin. Med., No. 3, s. 45, 1883.

[4] See page 268 of this number of the JOURNAL.

enlarged by the intimate relation in which the micro-organisms stand to such purulent processes.

The fact that the glands in this case had not only become cheesy, but had caused a neurosis of the tissue in their neighborhood, suggested that there was more of a septic process in this case, the usual course being a dry caseation or calcification.

As regards the possibility of this being tuberculous instead of simply hyperplastic, he had been unable to find the ordinarily recognized miliary tubercles either here or in other organs. If, however, we are to regard, with Koch, that all cheesy degeneration is to be considered as due to the agency of the same bacillus as is found in miliary tuberculosis, our conception of this process would have to be as comprehensive as that of Louis and Laennec. In the specimen here he had been unable to convince himself of the presence of a specific organism, but as yet he had not been successful in detecting it in tissue, although it was easily found by double staining (Ehrlich method) in the sputa of consumptives.

DR. ROTCH, in reply to an inquiry by Dr. Gannett, said that it was a characteristic of these cases that the bowels were not distended, and this lack of tympanites rendered the diagnosis more difficult. If one should find a distended and tender abdomen, with constant vomiting, one would be more likely to think of peritonitis.

DR. GANNETT said that in certain cases of autopsy after death from cholera infantum he had found the abdomen very much distended. He had ascribed the distention to the acuteness of the disease. The autopsies had been made about twelve hours after death, during the summer, but the cadavera had been kept on ice.

DR. MCCULLOM said that distention of the abdomen before death had been rare in his cases of cholera infantum, or, in fact, in any case of abdominal disease, and he suggested that the distention might be due to post-mortem generation of gases in the intestines.

DR. PUTNAM said that it probably depended on whether we had to deal with an acute or chronic disease. When a child has chronic enteritis, and dies suddenly, the conditions are entirely dissimilar from those occurring in an acute case. In the sudden collapse of a comparatively healthy child the abdomen is sunken. Otherwise it is likely to be distended. It is quite common for physicians not to distinguish the various forms of diarrhœal disease in children, but to confuse them all under the term cholera infantum.

DR. DENNY said the allusion of Dr. Whitney to the agency of bacilli in the causation of disease suggests a field of study which seems to promise an eventually satisfactory solution to the obscure pathological problem involved, not only in the case reported, but in others where certain caseous, purulent, or any foreign deposits occur, without sufficient explanation from generally received doctrines.

The fact appears to be pretty well established, as shown by the recently published report of Professor Arnould,[1] that foci of disease may be artificially produced by the experimental cultivation and inoculation of various micro-organisms, as bacilli, micrococci, microbes, penicillium, mycelium, etc.

Thus, according to Arnould, Recklinghausen first discovered micrococci in purulent deposits found in typhoid fever in 1871, and Klebs furthermore gave the name of "bacillus typhosus," somewhat prematurely, to a micro-organism, which he cultivated and produced experimentally, and found in the blood-vessels, larynx, and in necrosed masses of the intestines. Likewise Letzerich recognized "typhogenic cocci" in the blood, connective tissue, and parenchyma of the liver, kidney, intestinal walls, spleen, and lungs, while Brautlecht injected fluids presumed to contain "typhoid bacilli," subcutaneously into rabbits, and produced intestinal inflammation, tumefaction of the spleen, mesenteric glands, and Peyer's patches.

Furthermore, Wernick even ventures to affirm that a "bacillus typhosus," that, he says, is inoffensive when it does not pass beyond the large intestine, the walls of which it cannot penetrate, may, under favoring circumstances, reach the small intestines, penetrate its glands, and so attack the spleen, liver, and other tissues.

It does not appear that the characteristic features of typhoid fever are thus reproduced, and Arnould does not think that we are yet warranted in saying that there is a typhoid parasite, but the inference seems justifiable I think, that bacilli and various micro-organisms may, under certain conditions favorable to their cultivation within the human body, act as foreign bodies, and thus set up irritative lesions in an obscure manner, especially in the intestinal tract and its appendages, which may be marked by pathological deposits of various character.

Thus Arnould states that these micro-organisms have an almost indefinite aptitude to vary their properties according to the conditions of their environment under the influence of certain external agencies.

It is not improbable that the microscopic search of purulent or other foreign pathological matters, as in the case detailed, for microbotanic organisms, etc, will some time reward us with a clearer ætiology, as well as promote the efficiency of our hygienic and therapeutic measures.

DR. BOWDITCH asked for a statement as to the amount of confidence which should be placed in the published results of Koch's investigations into the bacillus of consumption. Can we accept it as an established fact that such a germ exists and is the cause of tuberculosis, or is the disease merely the habitat? If consumption is due to the bacillus, it seems that we ought to find more evidence of active contagion than at present appears. While he believed that consumption was contagious to a certain extent, yet this feature is not well marked or easy to demonstrate. The general and symptomatic evidence is rather against the existence of such a microscopic germ as a cause of tuberculosis.

DR. WHITNEY in reply gave a brief recapitulation of the experiments of Koch, many of which had already been confirmed by other observers, and considered that they showed quite positively that a specific germ in tuberculosis does exist.

Adjourned.

[1] Etiologie et Prophylaxie de la Fiebre Typhoide. Rapport fait au quatrieme Congrés International d'Hygiene en Septembre, 1882. Par le Dr. Jules Arnould, Professor de Faculte de Lillé. Annales d'Hygiene Publique, etc. Septembre, 1882.

— Philanthropic old lady: "So you have got twins at your house, Johnnie." "Yes 'm, two of 'm." "What have you named them?" "Thunder and Lightning, ma'am." "Why, what very singular names!" "Yes 'm, that 's what pa called 'm as soon s he heard they were in the house."

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL SCIENCES.

W. W. GANNETT, M. D., SECRETARY.

DECEMBER 19, 1882. DR. AMORY presided.
DR. BOWDITCH showed

BELL'S INDUCTION BALANCE AND ELECTRIC PROBE FOR THE DETECTION OF BULLETS WITHIN THE BODY.

The former Dr. Bowditch explained as consisting of a perfectly adjusted induction balance, having two large coils firmly imbedded in paraffine and set in a convenient wooden handle. A smaller pair of coils, movable upon one another, allows of adjustment of the apparatus.

In use, the current from six cells is passed through the large primary coil and one of the smaller coils, a double interrupter being placed in the circuit.

The wires from the large induction coil are connected through the other small coil with a telephone.

Adjustment is obtained by holding the large coils away from any metal; then with the telephone to the ear the smaller coils are moved upon one another till no sound is heard. If now the handle containing the larger coils be brought into the neighborhood of bits of lead or other metal, a musical note is heard caused by the interrupter in the primary circuit.

Bullets buried in meat were readily detected, and a piece of a sewing-needle six millimetres long produced a distinct sound when held one inch from the coils.

The electric probe consists of a long steel needle connected by a wire with a telephone and a thin steel disk similarly connected.

In use, the steel plate is moistened and placed beneath the suspected part. The needle is then thrust into the flesh, and on touching a metallic object (like a bullet) a sharp sound is heard in the telephone, owing to an electric current being established, the bullet and the steel plate forming the two poles of a battery.

Dr. Bowditch mentioned two cases where the situation of a bullet within the human body had been determined by means of the induction balance.

In reply to questions Dr. Bowditch said that the electric probe was of advantage only in distinguishing between bone and metal; further, that in using the induction balance it made no difference in the sound produced whether the bullet or like was imbedded in muscle or not.

The regular business of the meeting was a discussion on

THE RELATION OF THE GERM THEORY TO SURGICAL PATHOLOGY,

Drs. J. C. Warren, Fitz, and Whitney, being those appointed to take part.

DR. WARREN gave some account of the present knowledge of the relation of bacteria to inflammation, abscess, septicæmia, and pyæmia; stating the views of Burdon-Sanderson, Cheyne, Pasteur, Koch, Chauveau, Billroth, and others; the general weight of evidence going to show that they were to be found in the infectious inflammations; in acute diseases; in septicæmia and pyæmia; but that a specific character could be given to the organisms found in these diseases in man was not yet established, although Koch and others maintained a specific bacterial origin for some of these diseases in animals.

DR. FITZ said that the difficulty of associating specific germs with specific diseases was very great.

Numerous experiments with reference to the solution of such problems have been made on lower animals, but neither now nor probably in the future can there be opportunities afforded for thoroughly controlled experimentation on man.

The recent great advance in our knowledge of the subject is the result of the investigations by Koch, who has shown that it is not only necessary to *discover* organisms in disease but also to *identify* them in their varying conditions.

In the recognition of the tubercle-bacillus the color-reaction is the ultimate test, and unless all the conditions for its performance, especially the strength and purity of the reagents, are adhered to the reaction is not obtained. That there is an opportunity for the application of much ingenuity in such investigations is apparent.

Bacilli may be of the same form and size and yet have different properties. Further, one must be sure in cultivation that there are no contaminations; hence the importance of suitable soils and of a solid medium in particular is apparent, for by the latter means one can isolate and cultivate purely. It is possible, in certain cases, by inoculation of such distinct micro-organisms to produce certain diseases.

Wood and Formad have maintained the idea that the ordinary micro-organisms of putrefaction are sufficient, under proper conditions, to produce diphtheria; if this claim is admitted, it is obvious that a well-characterized disease is the result of complex agencies rather than one well-characterized.

As a general conclusion it may be said that unless all of Koch's conditions are fulfilled one can only say that the bacteria and the disease are associated.

The endeavor to discover a specific organism as the cause of the diseases of wounds has led to the isolation of a microbe which occasions erysipelas.

It has been observed that thrombi forming in vessels treated with Lister precautions are eventually replaced by fibrous tissue without local or general disturbance, whereas putrid softening results if the wound is besmeared with putrid material. It is to be said, however, that no one has yet recognized a specific micro-organism as a cause for this softening, although numerous organisms are present in the putrid material. As no specific cause for the putrid softening is isolated, so no distinctive organism for pyæmia or septicæmia in man is found.

In suppurative processes, whether on surfaces or in deeper tissues, micro-organisms are frequently found, and, if present at all, must come from without. But apparently the presence of such organisms is not a necessary factor in suppuration, as has been shown in the cases of inflammation resulting from the injection of petroleum beneath the skin.

Although specific organisms are admitted as a cause of certain diseases, it is obvious that in putrefactive processes there are numerous varieties of microbia, and it is necessary to determine the effect of each, isolated, before the relation of putrefaction to disease can be determined.

DR. WHITNEY mentioned some of the difficulties encountered in investigations upon lower organisms, and described several of the methods of staining such organisms, more especially with reference to the bacillus of tuberculosis.

Dr. Whitney also exhibited a preparation showing the bacilli, stained with methyl-blue, which Koch considers to be the specific organism of tuberculosis.

Meeting, January 16, 1883. The regular paper of the evening was by Dr. Wadsworth on

THE APPARENT CURVATURE OF SURFACE CAUSED BY PRISMATIC GLASSES.

Dr. Bowditch opened the discussion by saying that, "The manner in which our judgment of the size of visible objects depends upon our estimate of their distance may be illustrated by means of stereoscopic figures. If we draw upon a card two pairs of stereoscopic diagrams representing similar truncated pyramids, with their smaller ends turned in one pyramid toward, and in the other, away from the observer, it will be found, when the figures are viewed through a stereoscope, that the truncated end appears smaller in the former than in the latter pyramid, although in the diagrams they are of precisely the same size.

"The illusion depends upon the fact that, since the two truncated ends subtend the same visual angle, the one which is at a greater apparent distance must be supposed to have a greater absolute size. In this case the illusion is helped by the circumstance that the two pyramids, though drawn on the same card arc, do not form part of the same diagram. Hence no very direct and close comparison of the size of the truncated ends is possible. The illusion persists, however, in the case of a single stereogram representing two truncated pyramids or cones placed base to base, and having the line joining the centres of the two truncated ends, forming a small angle with the line of vision. In this case the two truncated ends appear side by side, and therefore in the best possible position for judging of their comparative size. Although drawn of precisely the same size in the diagram the more distant end seems invariably the larger. Even when the figures are so drawn that in one of them the two squares representing the truncated ends have one side in common, the illusion is not disturbed, but if the axis of the pyramids so nearly coincides with the line of vision that the two squares overlap each other to any considerable extent, the illusion is greatly weakened, though not wholly lost.

"Figures of this sort illustrate the principle that the size of the retinal image, when uncombined with any knowledge of the distance of the corresponding object, furnishes little or no information as to its absolute size."

SPECIMENS OF TUMORS AND DISSECTED NERVES.

Dr. J. J. Putnam gave the clinical history, and showed the specimen of a case of glioma of the pons Varolii; also showed several microscopic sections of the tumor.

Dr. M. H. Richardson showed a dissection of the superficial nerves of the hand.

The skin is removed entire, like a glove, being turned inside out by the process. By this means the nerves may be traced to their terminations, affording, at the same time, a good opportunity for observing the Pacinian bodies.

Dr. Richardson also showed a hypoglossus nerve having a ganglion at the point where the nerve passes beneath the digastric muscle.

A vagus with an enlargement at the point where the recurrent laryngeal is given off was also exhibited.

Dr. J. C. Warren showed microscopic specimens of a xanthoma removed by him from the eyelid of a patient of thirty-five years of age, and gave, in connection with them, an account of the various views held as to the nature and origin of these growths.

Dr. Warren also presented microscopic sections of a tumor of the parotid, of six months' growth, which he considered to be a cancer.

EXPERIMENTS WITH ARTIFICIAL DIGESTIVE AGENTS.

Dr. Edes showed the results of some experiments made with artificial digestive agents.

Solutions, containing each one half gramme of saccharated pepsin, ingluvin, and lacto-peptine were added to equal amounts of egg-albumen. In the case of the pepsin the albumen was soon dissolved for the most part. In the case of the two remaining agents no soluble effect upon the albumen was to be observed.

Recent Literature.

Die Allgemeine Elektrisation des Menschlichen Körpers. Elektrotechnische Beiträge zur ärztlichen Behandlung der Nervenschwäche (Nervosität und Neurasthenie) sowie verwanter allgemeines Neurosen. Von Sigmund Theodor Stein. Halle. 1882. Pages viii., 73. [General Electrization of the Human Body. A Contribution to the Technical Study of the Medical Use of Electricity in treating Nervous Weakness and allied Neuroses.]

Any one who has Beard and Rockwell's work on Electricity will not need this. Dr. Stein simply gives an account of their methods of general electrization, adding thereto a description of the electrical bath and the use of static electricity for the same ends. He considers central galvanization unnecessary.

A Dictionary of Medicine, including General Pathology, General Therapeutics, Hygiene, and the Diseases Peculiar to Women and Children. By various writers. Edited by Richard Quain, M. D., F. R. S. New York: D. Appleton & Company. 1883. 1816 pages.

The Medical Dictionary of Dr. Quain is something more than its title would at first indicate. It might with equal propriety be called an encyclopædia. The different diseases are fully discussed in alphabetical order. The description of each includes an account of its various attributes, often covering several pages. Distinctly surgical matters are not included in the book.

The book has been edited with the greatest care with the intention of preserving the unity of the volume, a matter not always easy, when many authors unite. The articles are condensed with very great care and are signed, so that the reader knows on whose authority he is asked to accept the statements.

One must not expect in this single volume the exhaustive articles of the *Nouveau Dictionnaire* or Ziemssen's Encyclopædia, but he will find the modern ideas on various subjects tersely put by men whose names are a guaranty of the truthfulness of their work.

The list of contributors is a striking one. The names of those who have already been taken away by death since their articles were written will serve as an index to the character of those who survive. Edmund Parkes, Charles Murchison, George Callender, Thomas Bevill Peacock, John Rose Cormack, Lockhart Clarke, Tilbury Fox, Thomas Hayden, Harry Lerch, Alexander Silver.

Any attempt to discuss the separate articles seems superfluous. Although we have possessed the book only the short time since its publication, its loss would leave a void we should not know how to fill.

Twenty-Ninth Report upon the Births, Marriages, and Deaths in the State of Rhode Island for the Year ending December 31, 1881. Prepared by CHARLES H. FISHER, M. D., State Registrar of Vital Statistics. Providence. 1882.

This volume, while somewhat late in making its appearance, presents a careful record and classification of the vital statistics of the State. From it we note that the male births were considerably in excess of the female (3498 to 3263). There were 64 cases of plural births, one of them being triplets. The deaths numbered 5016, more than a quarter of which were caused by diseases of the lungs and respiratory passages. In 1881, as in every other year since the beginning of registration, consumption heads the list. Pneumonia stands second in order, as it has every year with two exceptions. Diseases of the heart and diseases of the brain have been gradually increasing as causes of death, the former taking the third place in 1881, and the latter the seventh. Croup has diminished in importance as a cause of death. The proportion of deaths under five years of age (32.8) was less than during any previous year recorded. Of the decedents over twenty years old the average age was 52.94. The aggregate numbers are not great enough to give much significance to the average longevity represented by most of the different occupations, but we may notice that the physicians averaged 66.37, the lawyers 61.50, and the clergymen 68.17.

We are particularly struck with the figures regarding divorce, especially in view of the remarks recently published from the Rev. Dr. Dix, of New York, in relation to the laxity of the marriage bond in New England. There were 268 divorces granted during the year, being one for every 10.4 marriages. The ratio of applications for divorce was one to less than every eight marriages. This proportion shows an almost constant increase since 1869, the first year that these returns were included in the registration reports. Of the 503 causes for divorce alleged in the 268 applications that were granted adultery comprised only 71.

Transactions of the Thirty-Second Annual Meeting of the Illinois State Medical Society held at Quincy, May 16–18, 1882. Chicago.

This is a handsomely printed and bound volume of 275 pages, and gives evidence of being the product of a healthy organization. The prominent part which has been taken by the Board of Health of Illinois in exposing incompetent practitioners and unearthing fraudulent transactions in diplomas is supplemented by three papers which were read at this meeting of the Society on Medical Education and Legislation, showing a most commendable disposition on the part of the profession to compensate for the slackness in these matters which prevail in some of the Western States.

Herbert Spencer on American Nervousness. A Scientific Coincidence. By GEORGE M. BEARD, A. M., M. D. New York: G. P. Putnam's Sons. 1883. 17 pages.

The chief interest of this little brochure is that it is virtually a posthumous work, perhaps the last which the author wrote. It is a comparison of Mr. Spencer's views as expressed in his speech, published in the *Popular Science Monthly* for January, 1883, with previous publications of the author. Besides this comparison there is mention made of the slowness and difficulty with which his views have been received.

THE APPROPRIATION FOR THE ARMY MEDICAL LIBRARY.

THE *Medical News* thus comments on the recent action of Congress on this subject: —

"In the debate upon the Army Appropriation Bill in the Senate, the amendment proposed by Mr. Logan to reduce the usual appropriation of $10,000 for the Army Medical Museum and Library to $5000 was stricken out, and on motion of Senator Conger $7000 was allowed for the Library, and $3000 for the Museum.

"The debate showed that few of the honorable senators knew anything definite about the Library or Museum, although we were glad to see that there was a general impression that they were valuable and useful. A letter from Dr. Billings to the surgeon-general was read, in which, among other things, it was stated that 'the demands upon the Library for books and information are steadily increasing, and there is not a week during which some books are asked for which it does not possess. During the past year, under the regulations which permit of the loan of books to other responsible libraries, books have been loaned to Boston, New York, Philadelphia, Baltimore, Chicago, Cincinnati, St. Louis, and other places, for use by physicians in those places.'

"Upon this Senator Logan commented as follows: 'That is not the way for the government money to be used, buying books to be distributed around over the country for the use of other people. If they want them let them go to the Library and examine them.'

"We should like to know what Mr. Logan means by 'other people.' He seems to forget that the government in this country is the people. We hope that some of his medical constituents will enlighten him in the course of the summer. They might also remind him that it is only asked that the books be put in the Government Library. All the expenses attending their use in other places than Washington are borne by the 'other people.'

"The result of the Senate's action is satisfactory as far as the Library is concerned, but the Museum gets too little. The two institutions should have together $15,000 per annum to make and keep them what they ought to be."

Medical and Surgical Journal.

POOR-HOUSE TREATMENT FOR LUNATICS.

As almost all of our readers know, our insane hospitals are now as full of patients as it is best they should be, and the question of further provision for the insane already demands consideration.

The existing hospitals being in most cases very well adapted for the treatment of acute cases of insanity, it is but natural to regard the chronic insane as the class which will need increased hospital accommodation first. To accomplish this purpose various plans have been suggested, such as enlarging our present hospitals, putting up separate buildings on our hospital grounds, building special, distinct hospitals, and utilizing a portion of the various alms-houses.

The last method of provision for the chronic insane, which is occasionally brought forward on account of the ease and economy with which it can be carried into effect, is the one that we shall speak of here.

Those persons who have the least practical acquaintance with the management of the insane are the ones who usually advocate this plan. Hospital medical officers and hospital trustees and managers, who have the direct care of the insane, are, as a rule, strongly opposed to placing the chronic insane in any institution other than a well-managed insane hospital.

Of the correctness of this opinion we have had numerous proofs in times past. Its latest confirmation we have found in a Report on the Chronic Insane in Certain Counties exempted by the State Board of Charities from the Operation of the Williard Asylum Act by Commissioners Letchworth and Carpenter. This report concerns the chronic insane of New York, and is made to the State Board of Charities by two of its members.

These persons, a lady and gentleman, were appointed to visit and make a report upon the condition of the insane departments of poor-houses in counties exempted by the Board from the statute requiring the chronic insane to be transferred to the Williard Asylum, and they visited these departments in sixteen different counties, with an insane population of 1286. In every county but one the insane department was an integral part of the poor-house establishment, being under the same financial and general control.

The total number of epileptics was seventy-seven. There were fourteen suicidal cases and thirteen homicidal cases.

The total number of crib-beds found was thirty-nine. There were thirty restraining chairs, forty-eight muffs, forty-three camisoles, thirty pairs of handcuffs, eight pairs of shackles, and forty-six pairs of wristlets and waist-bands. This makes a grand total of two hundred and forty-four pieces of restraining apparatus, or more than enough to restrain a fifth, or twenty per cent. of the whole. The Commissioners state that they found only thirty-seven persons actually restrained at the time of their visit; but as so much restraining apparatus implied the use of a free amount of restraint, they regarded it as best to discourage its use. When we see further on in the report how very small the number of attendants was in these poor-houses, and how little medical supervision was exercised over them, we can easily understand how such an immense amount of restraining apparatus might easily be brought into play (?) by the ignorant but perhaps well-meaning poor-house superintendent or keeper. We can also imagine how much suffering and abuse the unfortunate insane might be exposed to.

Theoretically these poor-houses are under medical supervision to a greater or less degree, that is, a doctor makes a visit once, twice a week, or daily, or when he is sent for, but he has no voice in the direct management, and his influence is not felt much more than that of any outside physician, we should judge, from the reports of the various poor-houses. In Oneida County, for instance, where there are in the insane department to the poor-house two hundred and seventeen patients, the attending physician is non-resident, is appointed by the poor-house superintendent, and beyond seeing all the almshouse inmates daily and giving them medical treatment, has little, if anything, to do with the management. The superintendent and matron attend to all details; the former arranges the dietary, and the attendants apply restraint, using for the purpose six cribs, four muffs, two camisoles, and straps and strong chairs. When restraint has been applied the attendants report *afterward* to the superintendent.

In twelve of the poor-houses there was no record of a medical nature. In two the patients were found locked up and left alone without attendants, like the children of an Irish woman who has gone out to do a day's washing. Most of the insane departments, with barred and grated windows, studded doors, heavy padlocks, high plank fences, etc., looked more like prisons than asylums for the insane. In many the drainage, heating, ventilation, and water supply were defective. The airing courts were small and contracted, with high fences that the insane could not see over. With the exception of four counties, in which the patients were allowed to play ball and quoits, no out-door recreation or amusement was furnished to either sex. In some counties the sexes were not properly separated. For instance, in the Chautauqua County Poor-House, the insane department of which contained eighty-one patients, and of which a record of filth and vermin is given by the Commissioners, the men's airing court and the women's ward were so arranged that at the time the Commissioners' visit was made the women were able to look down on to several half naked and indecently exposed men.

Further examples of the deplorable condition of many of these New York poor-houses might be given, but it is unnecessary in this place.

The Commissioners, in summing up their conclusions, state "that with few exceptions the care of the chronic insane in the counties does not attain to a just and proper standard. In some counties the deficiency is lamentable." But they add that the Williard Asylum Exemption Act is only a *temporary* measure, which excuses some of the shortcomings of the poor-house authorities. The State insane hospitals have never been able as yet, the Commissioners state, to provide for this large number of the chronic insane still remaining in county poor-houses.

It is the opinion of the Commissioners that the chronic insane should be cared for in institutions entirely separate in every way from poor-houses, which should be managed by a resident medical superintendent having the appointment and entire control of the subordinates.

We can say very positively, from our knowledge of the care of the insane in the past and at present, that as soon as any institution for the insane passes out of proper medical hands, as a rule, it begins to retrograde, and the tendency is always downwards until medical management is again resorted to. Insanity being a disease it seems to require the peculiar knowledge and experience gained by medical training to make its proper treatment understood. The lay world at large, though so jealous of the rights of the insane, does not always take the most humane and enlightened view of the form of public hospital provision their disease entitles them to.

APARTMENT HOUSES IN NEW YORK.

THE recent burning in New York of the "Cambridge" apartment house, with the loss of two lives, has directed general attention to the dangerous condition of many of this class of buildings, of which there are such vast numbers in that city, not only as regards fire, but also from a sanitary point of view. The manner in which such houses are sometimes put up and rented is thus graphically described by a builder in Harlem, a part of the city to which there is now coming a large influx of population: "We will suppose that a speculator wishes to commence operations. He first buys say from four to six lots of land, worth, perhaps, $50,000. He then contracts with a builder of the 'cheap and nasty' kind to build him a row of five double flat-houses, containing fifty flats in all. The walls just meet the requirements of the building law, but shave it as closely as they dare. The floors are made of bad timber, hastily put together. The inner decorations are cheap but gaudy, and the plumbing is criminally bad. In the centre house of the row a gold and blue sign is placed, which has 'The Garibaldi,' 'The Muldoon,' or some other high-sounding name upon it. A flag surmounts the whole structure, and tenants pour in, attracted by all the gold and glitter. If the building does not tumble down the people usually die from disease of some sort contracted through the lack of proper hygienic precautions. If, however, a fire breaks out they burn like rats in a hole, because fire-escapes are worthless in a shell of that kind. When this 'Muldoon' is finished the builder takes a mortgage on it for half its value as payment for his labor. The owner puts a second mortgage on the building for all he can get, and with the money on hand commences building another row of bad flats." Even many of the higher class apartment houses are open to many of the same objections. In speaking of them Dr. Edward H. Janes, the assistant sanitary superintendent, recently said: "One great difficulty with them is that they shade the streets too much. Their massive walls tower up a hundred feet into the sky, and, as I have had occasion to notice, two of these great buildings often face each other on a narrow street, so that it is impossible that the sun should get to their lower floors. The law upon this matter is a wretched one. It merely gives the Board of Health authority to require that 'air and light be furnished to all floors in any house where more than one family are living.' When a plan is brought to this department by a builder or architect we examine it, and if we find that an air-shaft running through each flat is projected we have to be satisfied, but we cannot order that the shaft shall be built of non-combustible material. But these air-shafts are a source of danger not less fatal, though more stealthy, than fire. For instance, we will say that an air-shaft is built in these houses of the usual material, which is simply a hollow square, six feet by six feet, inclosed with cheap lath and bad plaster. This shaft holds all the moisture which the atmosphere contains, and, as a result, the rooms through which it passes are rendered damp and unwholesome. Sickness in these flats is only a question of time. If a law were enacted giving the Board of Health the right to see that the hygienic arrangements of a flat or apartment house were properly constructed, and the building department the right to compel the holders to erect fire-proof buildings, there would be no more disasters like that at the 'Cambridge,' and the mortality in the city would not be so large as it is at present." The building law of 1881, although inadequate, has been of no little service, however, since before that date practically no sanitary requirements whatever could be enforced in flats and tenement-houses. This law does not affect buildings erected previous to its passage, and already, since it went into effect, there have been some fifteen thousand cases of violations of it.

MEDICAL NOTES.

— The following event took place in a small town not twenty miles from Boston, — in fact at North Reading. It is to be hoped that the School Board who gave public circulation to such an expression of their ignorance as to the public welfare may receive the just censure which they deserve: —

A physician from a neighboring town had occasion to visit a child in the town referred to, the child being ill with scarlet fever. As was his duty, in strict accordance with the laws of the Commonwealth, he wrote a simple notice of the case, and sent the same to the selectmen of the town, acting as a board of health. Thereupon appeared in the Annual Report of the school committee of that town, dated February, 1882, the following statement: —

"The school was closed two weeks during the winter term through the wild judgment of an out-of-town doctor. We do not care to speak his name, trusting in the future he will be more careful to know his business before assuming authority."

— The address of the president at the last annual meeting of the Missouri Medical Society on Quacks and Quackery in Missouri contains some interesting revelations. "An old fellow on the State line, who claims to be a root doctor, has but three medicines in his dispensatory. He names them respectively *Hibobalorum*, *Lobobahirum*, and *Hilobustem!* One is a cathartic, another an emetic, and the last a 'rank pizen,' which will burst his patients open. He makes the first by peeling the bark downward, the second by peeling it upward, and the last by peeling it around." These diverse effects are evidently dependent on dynamic changes produced in the drugs by the degree of agitation incidental to each of the several methods of treatment.

— One of the saddest deaths from chloroform of which we have any knowledge is reported from Portsmouth, Virginia. According to a newspaper account of the affair, the wife of a physician was chloroformed by her husband, and fourteen teeth were then extracted by a dentist, but the poor woman never recovered consciousness.

— "Condensed elephant's milk" is the somewhat ambiguous aliment suggested by a contemporary for infant feeding.

— A correspondent of the *Medical Times* (February 24th) relates a case of poisoning by the ingestion of one grain of sulphate of atropine, which was treated by the hypodermic injection of "sixteen to eighteen grains of morphia," under the influence of which the patient recovered. This enormous amount of morphia produced no symptoms of narcotism, and the patient had not been addicted to the use of the drug. It has been generally held that while atropia was a useful antidote for morphia, the converse did not obtain, and that even in the former case it was unsafe to exceed to any considerable degree the physiological dose of the antidote.

NEW YORK.

— The exercises of the forty-second annual commencement of the Medical Department of the University of the City of New York were held at the Academy of Music on the evening of March 13th, when the degree of Doctor of Medicine was conferred on 163 graduates. The valedictorian was Ernest R. Birkins, and the Rev. Dr. John Hall, chancellor of the university, made the address to the graduating class, as well as presented the Mott medals and other prizes The prize of $500, for the highest standing in the class, was taken by Henry P. Loomis, B. A., a son of Prof. Alfred L. Loomis. Gilmore's band furnished the music, and among the selections was the "March of the Class of 1883," composed by the leader in honor of the occasion.

— The Bellevue Hospital Medical College commencement was held at Chickering Hall March 14th. There were 167 graduates, and the valedictorian was E. A. Morgan, of Illinois. Prof. Samuel D. Gross, of Philadelphia, delivered the address to the graduating class, and among the good advice that he gave the young gentlemen was that they should marry early and wear cheerful faces; the only proper place for the lugubrious physician being in a monastery. He incidentally warned them against unseemly quarrels with fellow-members of the profession, and also against asking the age of middle-aged and maiden lady patients. In conclusion, Professor Gross urged upon the class with much earnestness and force a strict observance of the Code of Ethics of the American Medical Association, which, he said, was a true and faithful guide. It was the palladium of their rights, the ark of their safety, and he who dishonored it dishonored his profession. No prizes were awarded, but the names of the four special honor graduates, whose standing in scholarship entitles them to a position on the house staff of Bellevue Hospital, were announced.

— A child seven months old recently died from the absorption of morphia in the following lotion, prescribed by the family physician for a scalded hand: Carbolic acid, one and a half ounces, sulphate of morphia, twenty grains, and linseed oil, four and a half ounces.

— A boy eight years of age died of hydrophobia on the 13th of March, after two days' illness. Nearly three years ago he was bitten on the hand by a spitz dog, and the wound, which was cauterized, quickly healed.

— A concert given recently at Chickering Hall, in aid of the New York Diet Kitchen, added $1737 to the treasury of that excellent institution. For some time past it has maintained diet kitchens in three of the dispensary districts of the city, from which, on the written requisition of the house and visiting physicians of the dispensaries, invalid diet is dispensed daily.

— At the meeting of the Board of Trustees of Columbia College, held March 5th, a special committee, consisting of the Rev. Dr. Morgan Dix, the Rev. Dr. Talbot Chambers, Dr. C. R. Agnew, and Messrs. William C. Schermerhorn and John J. Townsend, to whom was referred a petition presented by the Association for Promoting the Higher Education of Women in New York, requesting that the trustees should extend the advantages of the college to properly qualified women, reported that in their opinion it was inexpedient to attempt to educate the sexes together in Columbia College. The Board of Trustees almost unanimously sustained the verdict of the committee, the only dissenting vote being that of Dr. Barnard,

president of the college. Resolutions were also adopted to the effect that, as to the education of women otherwise than in conjunction with the students of the college, the Board, whatever their opinions might be, were not at present in a condition to provide for it in the college; that the Board deemed it expedient to institute measures for raising the standard of female education by proposing courses of study to be pursued outside of the college, but under the observation of the authorities, and offering suitable academic honors and distinction to any who, on examination, should be found to have pursued such courses of study with success, and that the special committee should be continued with instructions to prepare a plan for carrying the above into effect.

— At a meeting of the Medico-Legal Society held March 7th Dr. O'Sullivan, chairman of a special committee appointed to investigate the sanitary condition of the public schools, stated that the committee was not as yet prepared to make a final and exhaustive report, but that there could be no doubt, from the observations which they had already made, that medical supervision and inspection of the schools ought to be secured as soon as possible. Nearly every one of the school buildings was badly lighted and ventilated, while the primary departments were over-crowded with young children, who required more air and light than those on the floors above. Alluding to the loss of life in the panic at the parochial school in Fourth Street, Dr. O'Sullivan remarked that if the building inspector of the district had attended to his business properly the disaster would never have occurred.

The paper of the evening was then read by William G. Davies, Esq., on the subject of Mysterious Disappearances and Presumption of Death in Insurance Cases. Some years ago, he said, life policies were issued containing a provision that no presumption of death should arise from disappearance until the policy should have been continued in force by the payment of premiums throughout the expectation of life of the person upon whose death the contract matured according to the company's table of mortality, reckoned from the date of the policy. This was probably the fairest rule for all concerned, as it gave the company what it had the right to expect when it issued the policy, and required the beneficiary to pay what he should have expected to pay. In the absence of any such provision the question of death was one of fact, and the rule of presumption appeared to be that if the insured was exposed to any circumstances of special peril such circumstances, conjointly with his absence, would justify the jury in finding the fact of death, but without such circumstances the mere unexplained absence would not sustain such a finding before the end of seven years. After that period the burden of proof shifted, so that it devolved upon the defendant company to prove that the insured was still living. At the conclusion of the paper ex Surrogate Delano C. Calvin read an opinion of his own in connection with the paper of Dr. O. W. Wright, of Detroit, on Experts and Expert Testimony, which was recently read before the Society.

Correspondence.

CONCERNING NEWPORT, R. I., AS A RESORT FOR CONSUMPTIVES.

MR. EDITOR, — My attention has been called by Dr. Brackett to a criticism of my views concerning Newport as a Winter Resort, by Dr. J. Hilgard Tyndale, of New York, in a late (February 22d) number of your journal, the views in question[1] being, mainly: —

(1.) That a local climate where consumption is confessedly rare is presumedly a good one for consumptives to come to.

(2.) That a presumedly good climate (the ocean climate, for instance) becomes provedly such where consumptives, introduced, are found to mend.

(3.) That a climate permitting a comparative out-of-door life during the winter is so far a favorable one for consumptives; and

(4.) That for chronic chest cases, or threatening such, which cannot go South if they would, or which will not go South while they can, it is an advantage to have a place near home, at the North, which is alike easily accessible during winter, and comparatively favorable for them in the main essentials.

Dr. Tyndale's Proposition I., "that the climate and soil (of Newport) do not particularly favor the development of phthisis among its inhabitants," is in accord with my own statements. He admits that "it is shown that Newport has a smaller ratio of mortality from consumption, both as compared to the population and the total mortality from all causes, than any other locality in Rhode Island; and, further, that in this State the ratio of mortality is smaller than anywhere in this country except the Northwestern States." He states, moreover, what I had not ventured to do, that "health reports from Newport show that both as to soil and (natural) drainage the city is as near perfection as any city on the Atlantic." In objecting that "Newport as a city is not the only one of its size on the Atlantic coast with such small percentage of deaths (from phthisis) as mentioned (12.92 per cent. of all causes)," he does not allude to the collateral facts that its mortality in proportion to population is but 1.53 per thousand, and in proportion to the total mortality but 12.23 per cent. In 1878 it was but 9.16, in 1880 but 9.43, in 1881 but 9.17.

Dr. Tyndale's Proposition II., "that the climate and soil (of Newport) are inimical to the arrest or cure of phthisis in any of its forms," is but an assumption of his own, and is based upon the following errors: —

(1.) He assumes that the statistics of Newport are of only comparatively well-to-do people. Upon the contrary, it has recently been ascertained by Mr. Ernest W. Bowditch, of Boston, during his house-to-house sanitary inspection of Newport for the National Board of Health, the results of which will hereafter be published, that almost, if not quite, one half of all the permanent inhabitants of Newport are European, mainly of the laboring class. Of the balance (American), a great many are very poor, — sailors, fishermen, and the like.

(2.) Dr. Tyndale states that no evidence is given of the cure or recovery of phthisical patients. As to

[1] New York Santarian, January 11, January 18, January 25, and February 8, 1883.

this he has evidently overlooked the testimony I presented from Dr. Francis H. Rankin.[1]

(3.) He denies that a given mortality is any criterion of "the whole number of those stricken with consumption, or something akin to it." This, if true, must be said of all other places whatever.

(4.) He implies that immunity among residents (natives?) of Newport does not guarantee immunity among immigrants into Newport. This point is, however, covered by the Newport statistics, for probably not one half of the (already one half) American population of Newport are Newport born. Many of the Newport-born emigrate to better their financial condition. The Boston, New York, and elsewhere born have immigrated here to increase their enjoyment of life, and to better their health and that of their children.

(5.) He considers, as he practically denies the possibility, under other conditions, of phthisical arrest or cure, that comparative equability of climate can only exist "in relative company with dryness." He can hardly, therefore, have had personal knowledge of Newport throughout the year, or, indeed, have been much upon the sea.

(6.) He more than intimates that he is one of the "dry" extremists of the day.

With the purely theoretical assumptions of Dr. Tyndale one need merely compare the statements of experienced and reliable observers like Sir Henry Holland, for instance, who says: "Amidst all the opinions and phrases current on this subject (the influence of the weather in relation to disease), it is singular how little real knowledge has been gained or applied to practice;"[2] or like Parkes, in whose judgment "the best climates for phthisis are those which permit the greatest number of hours to be passed out of the house."[3] Even Denison, of Colorado, a most eloquent advocate of the dry-climate theory, does not hesitate to acknowledge that it cannot be made the universal rule. If combined with a high altitude, as in his own region, "the more acute or severe the nervous symptoms," he says, "the more of an aggravating nature is the effect of elevation."[4] And again: "The more seriously the respiratory organs, etc., are impaired, the less is the elevation that will produce a given disturbance of them. The ultimate prescription, so far as elevation is concerned, should be from one thousand to three thousand feet *lower* than that at which a somewhat prolonged residence would be injurious to a given invalid."[5]

I must add to the above that Dr. Tyndale seems a little careless in his quotation of pneumonia statistics from the Rhode Island Registration Report for 1880. He compares the eleven cases of death from this disease in Newport city with the seven in the (outside) Newport County towns, neglecting to add that the population (15,693) of Newport city is nearly double that (8487) of the County towns. He mentions the total mortality (230) of Newport County for sixteen years. But he forgets to state that this sixteen years' record of Newport County, in the Report from which he quotes, includes the city of Newport, making a total population of 24,180 in the County, and a yearly average therein of but fourteen (14.37) deaths from pneumonia, or one to every 1682 of the living.

As for 1880, Dr. Tyndale should have said, had he given the exact facts in the case, and but made the usual computation, that while the mortality of the whole of Newport County was for that year, from pneumonia, one death to every 1343 persons, and that of the County towns alone was one to every 1212, that of Newport city was only one to every 1426, — a result very different from what he claimed. He made, moreover, a comparison unfavorable to Newport with Bristol County; 230 deaths from pneumonia in Newport County in sixteen years against 171 in Bristol County. While, however, there are 24,180 persons in Newport County there are but 11,394 in Bristol County. The yearly average of deaths from pneumonia in Bristol County during the period in question was somewhat over ten (10.62). The proportion to living population was one in every 1072, while that in Newport County during the same time was, as above stated, but one in every 1682. Again in favor of Newport.

In the succeeding year, 1881, as shown by the Twenty-Ninth Rhode Island Registration Report, issued since the date of Dr. Tyndale's letter, there were ten deaths from pneumonia in Bristol County, or one to every 1139 persons; seventeen in Newport County entire, or one to every 1422; eight in the Newport County towns outside of Newport city, or one to every 1060; and in Newport itself nine, or but one to every 1743.

The following shows the comparative fatality of pneumonia in every portion of the State of Rhode Island for the three years 1879–1881, in relation to all other specified causes: —

	1879	1880	1881
Washington County	6.81	7.40	9.73
Kent County	5.42	5.45	7.35
Providence County Towns	8.36	6.43	5.58
Providence City	7.72	9.36	8.17
Bristol County	4.96	12.45	4.93
Newport County Towns	4.40	6.67	6.84
Newport City	4.60	5.61	3.93

I had myself not entered into the question of pneumonia at all, as it seemed outside the investigation that I had undertaken. Dr. Tyndale appears to have done so for the purpose of drawing a preconceived deduction; another instance of the danger of attempting to make the facts, which were here (unintentionally, I believe) misstated, conform to a theory, and this a theory that proves not tenable in the case of Newport. Briefly stated, Dr. Tyndale's whole argument is the following: Certain climatic conditions favor the development of pneumonia, and pneumonia originates or intensifies phthisis. The climatic conditions referred to "may be" found at Newport. Therefore Newport *must* be "inimical to the arrest or cure of phthisis in any of its forms." Unfortunately for this assumption, both the phthisis and the pneumonia are but rarities at Newport, and the former, imported, does become retrograde. Dr. Tyndale's reasoning would have applied with equal force and with equal fallaciousness to Dr. Bow-

ditch's valuable paper in your journal a year or two ago [1] upon the Isles of Shoals as a Summer Resort for Consumptives. In each instance it is the ocean climate that is criticised and condemned.

You will allow me to present, from the recently received Rhode Island Registration Report for 1881, the following statistics in corroboration of those that I had previously adduced: —

I. Proportion of Deaths from Consumption to Population (per thousand) in 1881.

(1.) The whole State of Rhode Island, 2.56.
(2.) The northern portion of Rhode Island.
(a.) Providence County, outside the City of Providence, 2.36.
(b.) Providence City, 3.24.
(3.) The southern portion of Rhode Island.
(a.) Newport County entire, 2.12.
(b.) Newport County, without the City of Newport, 2.35.
(c.) Newport City,[2] 1.18.

The following shows this average for the past twenty-two years (1860–1881): —

(1.) The whole State of Rhode Island, 2.35.
(2.) The northern portion of Rhode Island.
(a.) Providence County, outside the City of Providence, 2.29.
(b.) Providence City, 3.06.
(3.) The southern portion of Rhode Island.
(a.) Newport County entire, 1.85.

A more recent period gives the following: —

(1.) The whole State of Rhode Island, four years, 1878–1881, 2.45.
(2.) The northern portion of Rhode Island.
(a.) Providence County, without the City of Providence, four years, 1878–1881, 2.30.
(b.) Providence City, six years, 1876–1881, 2.97.
(3.) The southern portion of Rhode Island.
(a.) Newport County entire, six years, 1876–1881, 1.73.
(b.) Newport County, without the City of Newport, six years, 1876–1881, 1.44.
(c.) Newport City,[3] seven years, 1875–1881, 1.53.

II. Proportion of Deaths from Consumption to Total Mortality (per cent.) in 1881.

(1.) The whole State of Rhode Island, 14.07.
(2.) The northern portion of Rhode Island.
(a.) Providence County, outside the City of Providence, 13 08.
(b.) Providence City, 16.03.
(3.) The southern portion of Rhode Island.
(a.) Newport County, without the City of Newport, 15.74.
(b.) Newport City,[4] 9.17.

The following is the average for the past few years: —

(1.) The whole State of Rhode Island, four years, 1878–1881, 14.20.
(2.) The northern portion of Rhode Island.
(a.) Providence County, outside the City of Providence, four years, 1878–1881, 13.88.
(b.) Providence City, four years, 1878–1881, 15.33.
(3.) The southern portion of Rhode Island.
(a.) Newport County, without the City of Newport, six years, 1876–1881, 12.46.
(b.) Newport City,[5] seven years, 1875–1881, 12.23.

III. Proportion of Deaths from Consumption to those from all known causes (per cent.) in 1881.

(1.) The whole State of Rhode Island, 15.12.
(2.) The northern portion of Rhode Island.
(a.) Providence County, outside the City of Providence, 15.16.
(b.) Providence City, 16.15.
(3.) The southern portion of Rhode Island.
(a.) Newport County entire, 14.74.
(b.) Newport County, without the City of Newport, 17.09.
(c.) Newport City,[6] 11.87.

The following shows this average for the past twenty-two years, 1860–1881: —

(1.) The whole State of Rhode Island, 16.96.
(2.) The northern portion of Rhode Island.
(a.) Providence County, outside the city of Providence, 18.18.
(b.) Providence City, 16.04.
(3.) The southern portion of Rhode Island.
(a.) Newport County entire, 14.06.

[1] This journal, January 6, 1881, page 1.
[2] From the City Records.
[3] From the City Records.
[4] From the City Records.
[5] From the City Records.
[6] From the City Records.

The average of this ratio for a more recent period, of seven years (1875–1881), will be found of interest: —

(1.) The whole State of Rhode Island, 15.47.
(2) The northern portion of Rhode Island.
(a.) Providence County, outside the City of Providence, 16.47.
(b.) Providence City, 15.42.
(3.) The southern portion of Rhode Island.
(a.) Newport County entire, 13.57.
(b.) Newport County, without the City of Newport, 1876–1881, 13.23.
(c.) Newport City,[7] 12.92.

The Rhode Island State Board of Health present one table that is of especial value for your Massachusetts readers. It is the following: —

COMPARATIVE PROPORTION OF DEATHS FROM CONSUMPTION TO THE LIVING POPULATION, PER THOUSAND, IN MASSACHUSETTS AND RHODE ISLAND.[8]

	1860	1865	1870	1875	1879	1880	1881
Massachusetts	3.70	3.68	3.43	3.47	3.04	3.08	3.15
Rhode Island	2.88	2.96	2.64	2.52	2.33	2.32	2.56

From which it appears that during the twenty-two years' period already considered (1860–1881) the mortality per thousand from consumption has averaged 3.36 in Massachusetts and but 2.60 in Rhode Island, a difference in favor of the latter State of nearly one quarter of the phthisical deaths.

The State Board alludes to the apparently diminishing mortality, of late years, from consumption in Massachusetts. Such as it is, precisely the same relative diminution is noticeable, as demonstrated above, in the State of Rhode Island.

As to the general climate of Newport the island stands in much the same relation in this respect to the remainder of New England as is held towards England by the Isle of Wight. The general climates of the two islands are not materially dissimilar. So long ago as 1835, in some comparisons he was making of particularly favorable local climates, Dunglison, of Philadelphia, gave the following.[9] It is the mean temperature of several years.

	Newport, R. I.	Newport, Isle of Wight.
Winter	33.82°	40.31°
Spring	46.87	49
Summer	68.70	63.09
Autumn	53.83	51.63

Newport has long been utilized by the profession in Philadelphia and New York in the conduct of various forms of struma, and a large proportion of the present all-the-year residents originally came to the island from those cities as seekers for health. Several of the Newport physicians are here, like myself, as chronic invalids, to obtain convalescence from serious or lingering constitutional disease. Eventually practitioners in Boston and other portions of New England will realize that they have a comparatively fair winter climate close at hand.

Yours sincerely,

HORATIO R. STORER.

NEWPORT, R. I., *March* 9, 1883.

LETTER FROM ST. AUGUSTINE, FLORIDA.

Mr. Editor, — The first of March, which in New England brings only a mocking promise of a far-distant spring, finds Florida in the full exuberance of spring itself. The air is everywhere pervaded with the fragrance of orange blossoms; strawberries and green peas are in season, and roses bloom in profusion. For a month past the woods have been brilliant with yellow jasmine, which covers the trees with rich masses of golden blossoms and fills the air with perfume. The voice of the mocking bird is already heard, preparing for the grand chorus of song which is soon to burst upon us.

February in Florida is like the New England June. Frost is long past, the deciduous trees are again clothed with foliage, and the temperature is charming, being usually between 60° and 70° F.

Although winter is spoken of in Florida, the term is really a misnomer, for winter here is unknown. In December and January, to be sure, many trees lose their leaves, an occasional light frost occurs, and overcoats are sometimes comfortable; but there is no weather colder than is found in New England in October and May, so that the intervening six months are practically dropped from the Florida calender and autumn merges into spring. Throughout the so-called winter the orange, magnolia, live oak, and many other trees retain their leaves, roses may be gathered every day, and the orange trees are magnificent, their wealth of golden fruit contrasting finely with their dark-green, glossy leaves.

St. Augustine is one of the choicest spots in Florida. It is one of the few places in our country where sea-air and sea-side pleasures can be enjoyed in midwinter. The sea-breezes exert an equalizing influence upon the climate, rendering it warmer in winter and cooler in summer than the interior. The east and southeast winds are soft and balmy, tempered by the Gulf Stream, which here approaches very near to the coast. Sea-bathing can be enjoyed in summer, and sea-water baths, artificially heated, in winter. The accompanying table will give an idea of the temperature during the past year. The figures are taken from the record kept at the United States Barracks, to which access has been kindly permitted me by the post surgeon, Dr. J. H. Patzki. The temperatures are those shown by the self-registering thermometer, and the monthly mean is computed from the means of the daily observations.

1882.	Maximum.	Minimum.	Monthly Mean.
January	81	31	63.80
February	79	38	61.31
March	85	45	65.38
April	88	58	70.84
May	89	64	73.04
June	93	63	79.03
July	94	70	79.02
August	95	69	79.35
September	89	65	76.61
October	84	54	73.31
November	78	36	61.16
December	78	27	55.01
1883.			
January	79	28	58.15
February	81	41	62.51

During the past winter there have been five frosts, occurring on the 30th of November, 1st and 2d of December, and 10th and 12th of January. None of these frosts were sufficiently severe to do any injury to the oranges. The same number of frosts occurred last winter, and yet this winter has been colder than its predecessor, with more rain and more northerly winds, the severity of the season throughout the country being felt to some extent even here.

Prominent among the advantages of St. Augustine as a health resort is its freedom from malaria. That this immunity has any connection with local conditions would probably be denied by some skeptics of the present day; and yet it is a very significant fact that no fresh-water ponds or streams exist in this vicinity. St. Augustine is nearly surrounded with salt water, has a salt marsh on its western side, and another in the very midst of the town, uncovered at low tide, but even in the immediate neighborhood of these marshes no malaria is found. At one period only, so far as I can learn, did malarial fevers exist here. During the war, in strengthening the earth-works around the fort, so much soil was removed from the vicinity as to leave a low place where the rain collected and stagnated between the fort and the city gates. Cases of chills and fever began soon after to appear among the residents of that neighborhood, and continued until the place was drained, about ten years ago, when they wholly disappeared. The disease never spread beyond the immediate vicinity of this marshy spot, on the north side of the town. This information I have derived from Dr. A. Anderson, a native and life-long resident of St. Augustine.

This freedom from malaria, together with the fresh sea breezes, renders St. Augustine attractive as a summer as well as a winter resort, and people flock here in summer from the interior of the State.

The country people, who come to town with their little two-wheeled carts, drawn by a half-starved pony or ox, show unmistakable signs of malarial poisoning. They live among the fresh-water swamps with which this flat country abounds. One of these men, whom I lately examined, had a spleen as large as his liver.

During the past fall St. Augustine was visited with an epidemic of dengue, or breakbone fever. It prevailed during the months of September and October, and nearly everybody was attacked. The proportion of cases has been estimated at about eight tenths of the population. Other places in this section were also visited by the epidemic, Jacksonville being attacked before St. Augustine. The disease is a very painful one, but fortunately never fatal. The epidemic had passed off before my arrival here in December, so that I have seen no cases, but I had an experience of it in the fall of 1864, when surgeon of a blockading vessel at St. Joseph's Bay, on the west coast of Florida. Out of a ship's company of one hundred men eighty were attacked. The symptoms were then the same as those described as occurring here, excepting that the eruption was less marked. This was of an erythematous character, most developed on the palms of the hands and soles of the feet. The onset was sudden, fever high, headache, backache, and pains in the bones excruciating, constipation the rule, and depression of spirits very great. I well remember with what difficulty, while holding on to my aching back, I clambered down to the berth-deck, which was crowded with men lying in their hammocks, groaning with pain and crying with homesickness. At that time I found quinine in full doses exerted a marked influence on the disease,

those patients who took twenty grains a day from the outset recovering within three days, while those who did not were generally sick from five to ten days. This treatment was not then usual, the authorities generally advising only an expectant treatment, but is now adopted with success, I understand, by many physicians in the South.

St. Augustine has no sewers, and although the health of the town has thus far apparently not suffered from this cause, yet they are undoubtedly needed, on account of the large and increasing winter population. One of the hotels has a private drain discharging into the bay, but the others have none. Much pains is taken, however, by the larger hotels to insure the daily removal of house-slops and the contents of privies, and the sandy nature of the soil and rapid drying of the surface tends to prevent putrefaction and to keep the air pure. A Northerner, however, would hardly like to drink the water of the shallow wells, not more than six feet from the surface, and yet the natives drink it with apparent impunity. Rain-water is used by the hotels and the best of the private houses, but as this sometimes becomes scanty in dry seasons artesian wells are being introduced, furnishing a good supply of water from a depth of about one hundred and eighty feet. This water at first smells and tastes strongly of sulphuretted hydrogen, but after a few hours' exposure to the air becomes sweet and tasteless. In boring these wells the formations encountered are: first, 35 feet of sand; second, 10 to 14 feet of coquina; third, 15 feet of sand and sandstone; fourth, 2½ to 15 feet of coral rock; fifth, 80 to 100 feet of marl; sixth, eight to 17 feet of hard rock; seventh, 20 to 35 feet of marl; eighth, a bed of rock of unknown thickness. It is at the surface of the last rock that the water is found. The character of this rock I have as yet been unable to learn, but it is probably a portion of the tertiary limestone or sandstone which forms the backbone of the Florida Peninsula.

The climate of St. Augustine is beneficial especially in bronchial and throat troubles and nervous disorders. The soft, mild air is soothing to inflamed mucous membranes and tranquilizing to tired and irritated nerves. It is also beneficial in the early stages of phthisis, and many consumptives have found here a new lease of life. For asthma it is probably one of the best places in the world.

Here the invalid who at the North would be confined to the house, breathing artificially heated air, and debarred from exercise, can live out-of-doors all winter, excepting a few days when it is more comfortable and safe to remain near a blazing wood fire. The fact that agreeable occupation for mind and body is never wanting in St. Augustine enhances its value as a health resort. The history of this "ancient city" dates back to 1565, its fort is one of the most wonderful and interesting structures in America, the town has a foreign and tropical aspect, with its old coquina houses and narrow streets, the orange groves are always attractive, the drives are pleasant, and the sea-wall, a mile in length, with its smooth granite coping, affords a delightful walk. There are also fishing, shooting, and the finest of sailing, and the North Beach, with its fine surf, is close at hand. Add to these the library, yacht club, and military post, the last possessing a fine band, and it is evident that pleasant occupation is never wanting, and that there is no more attractive winter resort than St. Augustine.

A few days ago I visited Magnolia, one of the most beautiful places on the St. John's River, whose elegant new hotel is perfect in every appointment. This has been for many years the winter residence of Dr. Seth Rogers, of Pomfret, Ct., who has enjoyed a fine practice at Magnolia and Green Cove Springs. Dr. Rogers now wishes to retire from practice, and offers for sale his charming cottage on "St. David's Walk." For a physician of experience, well known at the North, this offers an excellent opportunity for a winter practice.

Yours very truly, J. F. A. ADAMS, M. D.

ST. AUGUSTINE, FLA., *March* 1, 1883.

LETTER FROM FLORIDA.

MAGNOLIA, FLA., *February*, 1883.

MR. EDITOR, — While we sit here in the shade, enjoying the fragrance of the yellow jessamine or picking oranges from the trees, it seems almost impossible to realize that New England is still wrapped in ice and snow, and those people may well be envied who are able, by a journey of three days, to strike February and March from the calendar, and pass at once from January to June.

The glory of Florida is its spring climate, the country itself is less attractive, for as one passes up the St. John's from Jacksonville to Enterprise, a journey of some two hundred miles, one finds only the same low banks, densely wooded to the water's edge, and relieved here and there by hummocks of sandy ground, rising some twenty to thirty feet above the water-level, and often covered with neatly-kept orange groves.

From Jacksonville to Pilatka the river will average some two miles in width, winding in picturesque curves, and occasionally stretching out into broad lakes; but above Pilatka it becomes much narrower, the curves are so sharp that the steamer almost touches bow and stern in coming through them, and on the river there is scarcely room for two boats to pass; the scenery also becomes more tropical, for instead of the thick growth of oak, cypress, maple, and other trees which one finds below, we often see long rows of palms, some sixty feet in height, lining the bank or forming large groves, while here and there a black alligator suns himself on a convenient log, or a beautiful white heron starts from the swampy ground.

If one dislikes the river climate and longs for some salt air, he can leave the steamer at Tocoi, and the railroad will bring him in an hour to the picturesque old city of St. Augustine, which seems more like a piece of mediæval Europe cut out and transplanted here than a real part of our busy America. Here we can see the old Spanish fortress, built after the principles laid down by Vauban; the Catholic church, with its ancient chime of bells, recalls visions of Menendez and his terrible butcheries; while on the narrow streets, with their overhanging balconies, one often meets the officers and soldiers of the garrison, and on pleasant days the military band attracts visitors to the parade.

If one can imagine our east wind tempered by passing over the Gulf stream in the latitude of 30° he can get some idea of the refreshing breeze which invigorates the air and adds to the enjoyment of a climate which equals our finest days of June; the drives about the country are interesting, and, for those who prefer the water, there is abundant opportunity for pleasure-sailing in the protected harbor or along the coast.

In St. Augustine, however, one misses something of the quiet beauty of the St. John's; here at Magnolia we look out from the hotel across two miles of placid water, often without a ripple, and dotted here and there with ducks, for shooting is not allowed near the house. All around us is a grove of live oaks, with their evergreen leaves, and their branches hung with long streamers of gray moss, which seems like crape, and gives a sad look to the trees; then, if we go back half a mile, we come at once into the long stretches of "pine barren," which reach for miles and miles, and over which the breeze comes laden with a fresh, resinous flavor.

To the brain-tired person it is a pleasure to ride on horseback through these woods, their very monotony and the sighing of the wind through the long needles of this Southern pine has a quieting effect, and one can spend the whole day wandering over the bridle-paths which form the only roads, or striking across lots; for, unlike the marshy woods, there is no undergrowth here, except an occasional patch of scrub-palm, and one only needs a compass for a guide-post.

If one prefers the easier traveling by water, the numerous creeks which flow into the St. John's offer a tempting field for exploration, for one can row or paddle for miles up these winding streams, getting at every turn fresh pictures for a sketch, or catching the sportive bass, while on rainy days the fine hotel which Boston capital has this year finished here gives a chance for bowling, billiards, and other in-door amusements.

What is the other side of this picture? The river climate is damp and moist; through the month of January they have abundant rains, until it seems as if not only the land but also the air had become water-logged. There is a feeling of enervation; one day you are walking in such an atmosphere as one finds in winter in a city greenhouse, with the thermometer at 80°; during the next few days the temperature may drop to 32° degrees, so that one may have a touch of spring, summer, and autumn within a week. At St. Augustine the climate is more even, and at Cedar Keys, on the west coast, the weather is tempered by the milder breezes from the Gulf, but dampness and variability prevail.

In short, the impression left on the mind of a casual observer is, that Florida would be a paradise to the nervous and bronchial New Englander, a happy land where he might escape the rigors of his native spring, where his tired brain and congested larynx might find repose, but not the land to which the good physician would send his phthisical friend whose lungs had already become diseased.

T. H.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 10, 1883.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2962 (no report from New Haven): under five years of age 1001: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 495, lung diseases 503, consumption 489, diphtheria and croup 165, scarlet fever 78, small-pox 52, typhoid fever 40, diarrhœal diseases 34, whooping-cough 27, erysipelas 22, cerebro-spinal meningitis 20, malarial fever 19, measles 18, puerperal fever 18, typhus fever one. From *typhoid fever*, Philadelphia 14, New York and Pittsburg seven each, Chicago three, Brooklyn two, Boston, St. Louis, Cincinnati, Charleston, Brookline, Hyde Park, and Holliston one each. From *diarrhœal diseases*, New York nine, Buffalo five, Boston four, Baltimore three, St. Louis, Cincinnati, Providence, and Fall River two each, Philadelphia, Brooklyn, New Orleans, Pittsburg, Milwaukee, and Newburyport one each. From *whooping-cough*, New York nine, Philadelphia five, Cincinnati three, Boston, St. Louis, District of Columbia, and Pittsburg two each, Brooklyn and Chicago one each. From *erysipelas*, Philadelphia and Brooklyn four each, New York three, Chicago, Boston, Cincinnati, Milwaukee, Providence, Lynn, and Salem one each. From *cerebro-spinal meningitis*, Baltimore and Worcester three each, Milwaukee and New Orleans two each, New York, Philadelphia, Chicago, St. Louis, Cincinnati, Lowell, Fall River, Springfield, Taunton, and Woburn one each. From *malarial fevers*, New York seven, New Orleans six, St. Louis two, Brooklyn, Chicago, Baltimore, and Cincinnati one each. From *measles*, New York 10, Chicago and Cincinnati two each, Brooklyn, Boston, Pittsburg, and Peabody one each. From *puerperal fever*, Chicago four, St. Louis three, Boston, Buffalo, and Milwaukee two each, New York, Philadelphia, Baltimore, New Orleans, Nashville, and Springfield one each. From *typhus fever*, Philadelphia one.

Thirty-four cases of small-pox were reported from Baltimore, Buffalo five, Pittsburg three, Boston one; diphtheria 24, scarlet fever 23, typhoid fever five, in Boston; scarlet fever 15, and diphtheria nine in Milwaukee.

In 44 cities and towns of Massachusetts, with an estimated population of 1,229,855 (estimated population of the State 1,922,530), the total death-rate for the week was 19.00 against 19.31 and 19.94, for the previous two weeks.

For the week ending February 10th, in 171 German cities and towns, with an estimated population of 8,720,795, the death-rate was 25.6. Deaths reported 4301: under five years of age 1904; consumption 639, lung diseases 516, diphtheria and croup 217, diarrhœal diseases 142, scarlet fever 64, whooping-cough 45, measles and rötheln 43, typhoid fever 39, puerperal fever 21, small-pox (Posen and Heilbronn two each, Elbing one) five. The death-rates ranged from 13 at Erfurt to 38.2 at Posen; Königsberg 30.4; Breslau 29.4; Munchin 28; Dresden 25.2; Berlin 23.2; Leipzig 17.5; Hamburg 27.3; Cologne 23 1; Frankfort 20.3; Strasburg 26.8.

For the week ending February 17th, in 170 German cities and towns, with an estimated population of 8,684,911, the death-rate was 25.9. Deaths reported 4328: under five years of age 1837, consumption 658, lung diseases 595, diphtheria and croup 196, diarrhœal diseases 140, whooping-cough 73, scarlet fever 68, typhoid fever 53, measles and rötheln 28, puerperal fever 23, small-pox (Heilbronn and Metz one each) two. The death-rates ranged from 16 at Metz to 44.5 at Duisburg; Königsberg 30.1; Breslau 31.2; Munich 34; Dresden 23.6; Berlin 24.9; Leipzig 21.4; Hamburg 26.6; Cologne 24 8; Frankfort 18.4; Strasburg 26.8.

In the 28 great towns of England and Wales, with an estimated population of 8,620,975, for the week ending February 24th, the death-rate was 22.7. Deaths reported 3757: acute diseases of the respiratory organs (London) 366, whooping-cough 80, scarlet fever 79, fever 68, measles 44, diphtheria 36, diarrhœa 29, small-pox (London six, Portsmouth, Hull and Newcastle one each) nine. The death-rates ranged from 13.6 at Brighton to 32.3 at Wolverhampton; Bristol 17.9, Portsmouth 19; London 20.5; Birkenhead 21.2; Birmingham 23; Nottingham 25.1; Sheffield 27; Liverpool 28.3; Sunderland 29.7; Bolton 31.9. In Edinburgh 20.1; Glasgow 33.4; Dublin 35.7.

The meteorological record for the week ending March 10th, in Boston, was as follows, according to observations furnished by Sergt. O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 9, 1883, TO MARCH 16, 1883.

BROWN, HARVEY E., major and surgeon. Temporarily assigned to duty at Mount Vernon Barracks, Ala., during the absence on leave of Captain T. A. Cuningham. Paragraph 2, S. O. 17, Department of the South, March 6, 1883.

WILLIAMS, J. W., major and surgeon. Upon being relieved from duty at Fort Cœur d'Aléne, Idaho, will proceed to Fort Walla Walla, Wash. Ty., and report for duty as medical officer at that post. Paragraph 5, S. O. 24, Department of the Columbia, March 1, 1883.

CUNINGHAM, T. A., captain and surgeon. Granted leave of absence for twenty days, to take effect from the 21st instant. Paragraph 1, S. O. 17, Department of the South, March 6, 1883.

HEIZMANN, CHARLES L., captain and surgeon. To be relieved from duty in the Department of the South and assigned to duty at Columbus Barracks, Ohio. Paragraph 8, S. O. 58, A. G. O., March 12, 1883.

WOOD, MARSHALL, captain and surgeon. Is assigned to duty at Fort Cœur d'Aléne, Idaho. Paragraph 5, S. O. 24, Department of the Columbia, March 1, 1883.

A CORRECTION.

MR EDITOR, — In the report in Materia Medica of last week is one serious error which I should like to have corrected. Page 250, second column, below the middle, the paragraph beginning "Squibb, who has examined this, says . . . *twenty per cent. pure*," the twenty per cent pure should be omitted. What Dr. Squibb says is, "Duquesnel's aconitine cristallisée is, therefore, not what it purports to be, but is a nitrate of aconitia containing not more than 80.7 per cent. of the hydrated alkaloid."

W. P. BOLLES.

CORRECTION. — In our last issue, report of the Boston Gynæcological Society, the reader of the paper is given as W. S. Thom. It should be W. S. Brown.

Original Articles.

MISLEADING CARDIAC MURMURS AND EXPIRATORY AUSCULTATION OF THE HEART.[1]

BY HAMILTON OSGOOD, M. D.

THE cardiac murmurs to which this paper refers, being caused neither by valvular lesions, pericarditis, pleuritis, anæmia, nor by malposition or deformity of the general contour of the heart, but having, perhaps, led practitioners to suppose the existence of cardiac disease, may appropriately be termed *misleading cardiac murmurs*.

To the possible occurrence of murmurs in persons free from anæmia, and in whom the heart and lungs are normal, my attention was especially called a few years ago by the case of a young man, who applied for life insurance in a company for which at that time I was medical examiner.

While not strictly robust, this gentleman was in excellent health. His age was twenty-three; height five feet seven inches; weight one hundred and twenty-six pounds; chest expansion three inches; pulse 75, firm, full, and steady. The insurance company in question required two pounds in weight for each inch of stature. The applicant, therefore, was eight pounds below the standard, but, at his age, in view of the fact that his lungs were sound and his health good, this slight discrepancy was of no consequence. The formal examination discovered that he never had experienced any of the diseases concerning which he was questioned. Indeed, every step gave me satisfaction until I auscultated the heart, which organ it is my custom to examine last of all, in order that it may be as free as possible from the agitation which commonly attends this feature of life insurance. To my dismay I heard a murmur, distinct, systolic in point of time, its quality soft, yet suggesting friction, and located in the pulmonary area, with but little propagation. The area of percussion dullness was normal. The discovery of a cardiac murmur so very naturally leads the physician to infer endocardial disease, that I at once felt it my duty to reject the applicant. The more so because the young man's condition precluded all idea of an anæmic murmur. But financially at least, the risk was very desirable. Moreover, up to this juncture neither my questions nor examination had given me the slightest reason to suspect the heart. The most careful cross-examination failed to elicit any history of rheumatism, dyspnœa, difficulty of moving quickly, or to reveal even a hint of palpitation, or cardiac distress of any nature or degree. So far as I could learn, the applicant had always been in that enviable condition in which one is unconscious either of heart or lungs. Of active temperament, he could dance all night, ride horseback, play cricket, and outrun his fellows with ease and delight.

The inconsistency so apparent in this case, namely, a cardiac murmur coexisting not only with perfect freedom from dyspnœa of any degree, as well as from imperfect circulation, but also with absolute enjoyment of severe and prolonged muscular exertion, struck me as singular. I repeated my examination of the heart, in this instance being extremely observant of every sign, whether normal or abnormal. The first and second sounds were perfectly clear, clean, and distinct, still the first was closely accompanied by the basic murmur. When the lungs were fixed at the end of inspiration the murmur continued. During expiration, however, I remarked that it became less distinct. A sudden inspiration led me to place the gentleman so that his back rested firmly against a door opening into a small, bare-walled, carpetless room. It made an excellent resonator. I now requested him not only to exhaust but as far as possible to *collapse* his lungs and rigidly hold them thus. He did so, and to my surprise the murmur disappeared. Nothing but the distinct, well-marked, normal cardiac sounds could be heard. It was impossible to catch the slightest sign of a murmur. On full inspiration it reappeared. Repeating these procedures many times the results were invariable. The heart undoubtedly was normal and I passed the applicant, giving the abnormal sound merely the character of an attrition murmur, adventitiously caused by certain relations of the left lung to the heart. I felt justified in so doing simply because when the lungs were inflated I heard the murmur, when they were in partial expiration it became fainter, and when they were collapsed with force and the breath held, the sound disappeared. Fancying the question may arise as to whether this murmur would not have equally disappeared while the lungs were fixed during a full inspiration, I will say that I did not neglect this point. I found it mattered not whether the lungs during inspiration were or were not moveless, the murmur continued. Moreover, I was influenced by the positive assurance of the gentleman to the effect that he had never had pleuritis nor pericarditis. Indeed, had never known a day's illness.

In some of its features the case was new to me, and I could not find in any work on cardiac disease to which I have had access an instance wholly similar to this. References, which I will shortly give, are made to murmurs occurring in cases in which there was no disease of the heart. But, with one or two exceptions, I have found no especial allusion to changes caused by inspiration and expiration, except in so far as these respiratory movements may affect the intensity of cardiac tones and murmurs.

The case I have described is a type of other similar cases which have come under my notice; and these, therefore, do not require further mention.

The striking and complete disappearance of the murmur during expiration and its equally abrupt reappearance on inspiration in these cases, together with the procedures which I employed in studying its character, suggested to me a method of diagnosticating or proving the existence as well as absence of endocardial murmurs, namely, *auscultation of the heart during collapse of the lungs*. A merely ordinary expiration would not be sufficient, because there still would probably be considerable lung tissue between the thorax and the heart. The expiration must be forced and then be followed by supplementary expirations until the patient can expel no more air from the lungs, which for the moment must then be kept immovable. In theory I believe we then have an uncovered heart; that the valvular orifices lie close to the ear, and that by this means auscultation in every way is much aided. In fact I have found that while the murmur which I have been describing becomes gradually fainter and less audible during slow expiration, and wholly disappears on forced expiration, on the other hand, I have observed that true endocardial murmurs grow increasingly louder during expira-

[1] Read before the Boston Society for Medical Improvement, March 12, 1883.

tion, and become most distinct at the end of the expiratory act, especially when the lungs are held in a state of voluntary collapse. The process may be repeated for each one of the valvular orifices. The use of what I will venture to term *expiratory auscultation of the heart* has given me great satisfaction, for, where there is nothing wrong, the normal cardiac sounds, under this mode of auscultation, become sharper and more distinct, and conversely, where there is valvular imperfection, the endocardial murmurs are rendered much more evident. Indeed, the assistance I have derived from *expiratory auscultation* of the heart has been so great that I should consider imperfect an examination of this organ which did not include this procedure. Of course the neglect to compare all cardiac sounds heard during this expiratory collapse with sounds apparent during forced inspiration would be an error; but the truer proof, the more satisfactory certainty of the actual meaning of valvular murmurs, friction, and adventitious sounds, may be obtained during forced and sustained collapse of the lungs. It may be that this method of examination has been recommended by some writer on cardiac disease whose work I have not seen. As has been shown, some writers refer to the effect of respiration upon the quality and intensity of murmurs, but with one suggestive exception, I can find no allusion to the value of *expiratory* auscultation in proving the existence and in studying the character of true endocardial murmurs.

It is naturally a matter of interest to know what writers on cardiac diseases have said with reference to the manner and degree in which inspiration and expiration may influence cardiac sounds and murmurs. Von Dusch [1] says: "The intensity of murmurs changes with the respiratory movements according as inspiration has the power to weaken and expiration, on the contrary, to strengthen the action of the heart." Traube remarks: "Cardiac friction sounds increase in intensity during inspiration; endocardial sounds thereby become weakened."

Guttman,[2] Friedreich,[3] Skoda,[4] Gerhardt,[5] and others make the observation that the heart's tones are stronger during expiration than during inspiration, because, in the latter act, the thicker layer of lung tissue which lies between the heart and the thorax diminishes intensity. Friedreich adds that "in case of mitral murmurs greatest intensity will, during quiet respiration, be best heard in the fifth interspace, and during complete expiration will move upward to the fourth interspace."

Balfour [6] remarks that systolic murmurs of non-organic origin may *disappear* on deep inspiration, and quotes Quincke's [7] six cases in proof, meanwhile accepting his theoretical explanation of their cause, to the effect that in these cases the heart from various causes being uncovered by retraction of the left lung, a systolic murmur was produced by compression of the pulmonary artery against the chest walls during systole. The murmur disappeared on deep inspiration from interposition of the lung between the pulmonary artery and the thorax. Upon expiration the murmur reappeared.

Flint [8] quotes a case in which the murmur was accidental, but did not disappear when the breath was held, and there was coexistence of pleuritis.

Gerhardt [9] asserts that "the respiratory murmurs heard in the cardiac region are accidental, and while the breath is held after deep inspiration or deep expiration essentially change their character or disappear." In the cases which I quote, however, the murmurs accompanied the cardiac systole, and were not respiratory, because their frequency coincided with the repetitions of the cardiac systole.

In his work on the heart, Hayden says that pericardial friction sounds most frequently exhibit an inspiratory rhythm or periodic intensification corresponding to the inspiratory act.

Bauer [10] refers to the peculiar alteration of pericardial friction sounds by the respiratory movements, especially to the increase of the sound during inspiration. In reference to their confusion with endocardial murmurs and pleural friction sounds he quotes Ferber,[11] who locates the so-called pleuro-pericardial friction sound near the apex of the heart, in the vicinity of the tongue-shaped lobe of the left lung, and describes the modifications it undergoes during the various acts of respiration. Da Costa,[12] under the subject of Pericarditis, says: "A friction sound discerned over the heart may in reality be produced in the adjoining pleura. The patient is directed to suspend his breathing. The friction sound does not stop. Now the inference from this would be that the sound originated in the pericardium, and in the majority of cases this is a correct inference. But it is not always so. The friction sound may be engendered in the pleura, and be caused by the movements of the heart." He also alludes to the fact that a murmur may be obscured by the respiratory sound, and says that natural sounds of the lungs are sometimes mistaken for blowing sounds in the heart.

Irrespective of the effect of respiration upon cardiac tones and murmurs, and touching which so little is to be found, there are in the books many theories concerning the cause of sounds which simulate valvular murmurs and suggest endocardial disease. For example, Laennec [13] mentions cases of cardiac hypertrophy in which the lung is so compressed by the overgrown heart in systole that air is driven into the contiguous and connecting bronchial tubes, thus creating a murmur similar to that heard in valvular disease. Wintrich heard near the heart during systole a soft, breezy murmur simulating the inspiratory sound, and which he supposed to be an aspiration of air created by the systolic diminution of the size of the heart. Röser speaks of sounds (in the borders of lungs which were tubercular or contained cavities) heard synchronously with the cardiac systole.

Loomis [14] writes: "Sounds sometimes are heard in the precordial region produced by the action of the heart on the lungs. These sounds are mostly systolic and inspiratory; they usually cease to be produced when the respiratory movements are arrested. . . . A blowing sound resembling a cardiac murmur may be produced in the lung tissue covering the heart during a cardiac systole." In my cases suspended breathing

did not arrest the murmur. He further says: "A pulmonary cavity near enough to the heart to be influenced by it sometimes affords a loud systolic murmur."

Walshe states that he has known mere vascularity of a very small surface, without a particle of lymph, to produce a faint rubbing sound. "This," he says, "is, however, sometimes observed when the membrane may be presumed to be entirely healthy."

Flint[1] remarks: "I have occasionally discovered in auscultating the heart a slight rubbing or grazing sound accompanying the systole when there were no grounds for suspecting any cardiac disease." Gerhardt[2] says: "There are occasionally accidental murmurs, mostly systolic, though now and then diastolic, which are confined to a very limited area and *do not* accompany the tone. These accidental friction murmurs I believe, and have proved it by many autopsies, must be considered the result of pericardial friction." This is the opinion which I formed as to the origin of the murmurs in my cases, and for reasons concerning which I have a theory which I will shortly give.

Quincke,[3] quoted by Balfour,[4] says that in rare cases of mitral stenosis accompanied by hypertrophy, but not dilatation of the right ventricle, but with dilated pulmonary artery, the fluid vein caused by the passage of the blood through the comparatively small opening into the dilated artery will cause a (basic) murmur. I should mention the very interesting phenomenon mentioned by Bamberger, Von Dusch, and others, and rightly explained by Naunyn,[5] of a basic systolic murmur, presumably a pulmonic arterial bruit, but proving to be a fluid vein of mitral regurgitation producing a louder sound at point of impingement in the left auricle than in the mitral area, and heard, therefore, with greatest intensity over the left auricle, and consequently to the left of the pulmonary area. Other writers, Graves, Latham, Gerhard, of Philadelphia, Hope, Trousseau, Von Dusch, Oppolzer, Niemeyer, etc., in their various works, refer to murmurs apparently cardiac in origin, but heard during the coexistence of some affection of the lungs, especially of tubercular nature. Friedreich,[6] however, says: "All these murmurs, when caused by movements of the heart against the lungs, whether the latter be normal or diseased, disappear so soon as one auscultates during deep inspiration." It will be recalled that in my cases inspiration intensified the murmurs. To multiply quotations is needless, especially so in view of the fact that some abnormal condition accompanied nearly every case which I have cited. In my own cases the heart, lungs, and their envelopes were normal.

I have quoted all these luxuries among cardiac murmurs, as a matter of interest, to show what might have caused the murmurs in my cases, supposing I erred in my diagnosis, which I hope to prove was correct. But, first, may I ask you to observe that save the necessary reminder of the usefulness of the respiratory movements in the diagnosis of pericarditis and pleuritis, little is said by writers on cardiac disease in reference to the value and effect of *forced expiration*. That is to say, the books either make no allusion to the matter, or, when they do mention it, dismiss the subject in a few words. Hope[7] says: "The heart comes into more than ordinarily extensive contact with the chest during expiration. Under this condition impulse is stronger and the first sound louder. The auscultator will know how to avail himself of this fact in the exploration of disease, and make due allowance in his estimate of sounds and impulse." With this imperfect exception, and unless I have been unsuccessful in my search, no writer whom I have consulted on this point *emphasizes* either the necessity or usefulness of auscultating the heart during forced, complete, and fixed expiration. It is during *collapse of the lungs*, the breath *being suspended*, that faint endocardial murmurs, not otherwise audible, would be likely to become evident. It is then, too, that certain adventitious murmurs, heard when the lungs are inflated, disappear. *Expiratory auscultation*, therefore, is an aid too valuable to be omitted, even in a superficial examination of the heart. But in using this method of examination it should be remembered that the lungs must be forced into temporary collapse and the breathing then be arrested.

These remarks would be incomplete were I to omit the expression of an opinion as to the probable nature and cause of the systolic murmurs referred to.

At the outset all pathological causes may, I believe, be excluded. The murmurs were not *hæmic*. This is assured by the condition and history of my patients. They were not due to *pericarditis*. This is shown by their purely systolic occurrence, by absence of all other indications of this disease, and especially by their disappearance on expiration. They were not *pleuritic*, otherwise they would have been either synchronous with the respiratory movements or affected by them, and presumably would have been arrested on suspension of breathing, the fact being that they were intensified by inspiration, whether the respiration were or were not arrested. They were not the *pleuro-pericardial friction sounds* described by Ferber, because they were basic, and not heard near the apex of the heart, as his murmurs mostly were; and, moreover, there was no friction sound synchronous with respiration. The history of my cases excludes tubercular roughening of the edges of the lungs, and in this contingency there probably would also have been friction sounds accompanying the movements of the lungs.

They were not due to *emphysema* in the left lung, else they probably would not have disappeared on forced expiration, which, this lesion having existed, would have failed to remove the lung from the anterior surface of the heart. Moreover, the lungs of my cases were normal in condition. *Deformity* did not cause these murmurs, for it did not exist. They were not blowing sounds caused by systolic impulse of normal heart against normal lungs, because they contained no respiratory element.

They undoubtedly were not the *systolic aspiratory murmurs* of Wintrich, because they continued almost to the end of the expiratory act, at which period it would seem impossible for the cardiac systole thus to influence the air of the lungs.

They were not due to *compression of the pulmonary artery*, as described by Quincke, because inspiration intensified them. His were heard during expiration, and, for reasons already given, disappeared on inspiration.

They were not the *mitral regurgitant murmurs* of Naunyn, and heard in the pulmonary area, because they di appeared on expiration. The Naunyn mur-

murs, being endocardial, naturally were made more evident by uncovering the heart in forced expiration. For the same reason the murmurs in my cases were not endocardial. What, then, was their cause?

In the absence of positive information my own theory is that these murmurs were due to some slight, probably congenital, irregularity of surface in the pericardium near the base of the heart. During the act of inspiration, pulmonary pressure increased the friction created in systole and intensified the murmur. During expiration, the pulmonary pressure being gradually removed, the murmur likewise became less and less apparent. Finally, on collapse of the lungs with arrested respiration, all pressure upon the wrinkled or irregular surface, or surfaces, of the pericardium was removed, and therefore the murmur ceased. It was purely systolic, probably because the irregular pericardial spot being confined to a limited area near the base of the heart a suspension of friction occurred during diastole, when the heart is relaxed, is less convex than in systole, and has no impulse. The sound recurred during systole, in which the base of the heart is thickened, and the whole organ thrown forward by the impulse of a recoil which is accompanied by cardiac rotation. Even in pericarditis, a large surface being roughened by lymph, the diastolic portion of the common to-and-fro friction sound is usually relatively feeble. If this roughening were confined to a very small area near the base of the heart there presumably would be heard little or no diastolic friction sound. My diagnosis, then, is *systolic* and *accidental pericardial friction sounds.*

CONSUMPTION IN NEW ENGLAND.

BY E. P. HURD, M. D.,
Chairman Board of Health, Newburyport, Mass.

I.

IN studying the march of consumption in New England, we select the city of Newburyport, Mass., as the type of an old-fashioned New England city, with a population that has been nearly stationary the past forty years. If there has been any change in the population it has been in the direction of an increase of the foreign element, coincident with the development of manufacturing interests the past two or three decades. A considerable part of the native population occupy homes that have been a family inheritance for several generations. An old sea-port and fishing town, many of the leading inhabitants with pride trace back their ancestry to the original settlers of this country. Add to this that the city has salubrious surroundings, and is remarkably free from malarious and zymotic diseases, yet from its situation, on a declivity near the ocean, is exposed to chilly winds and inclement weather, and thus presents, as much as any city in the Commonwealth, the suitable climatic conditions for the development of consumption.

I have, at the cost of a great deal of time and labor, compiled statistics of the mortality from pulmonary phthisis in this city for the past twenty-five years. These statistics will be published in full in the next report of the Newburyport Board of Health. I have thought that the results might interest the readers of the Boston Medical and Surgical Journal. The preparation of statistics always involves the expenditure of much toil and research, and few readers are interested in the presentation of a formidable array of figures; all, however, are anxious to obtain the results. It is understood by all who have ever made such statistics that only approximate accuracy can be obtained, for death returns (often made hap-hazard) are notoriously unreliable; it is, however, true, that such as record consumption are likely to be the most reliable of any. Add, moreover, that no very startling conclusions can be expected from statistics embodying the data of only a brief series of years, while hints may certainly be obtained as to the tendencies of great natural laws which slowly but surely work out their results.

First, then, my statistics show a total mortality from all causes, for twenty-five years, of 7234; the average population being 13,500. Of these deaths 1235, or very nearly one sixth, were from consumption. Consumption, then, is still the most potent cause of mortality here, as elsewhere.

There is general harmony between these statistics and those published by Dr. J. Curtis in the *American Journal of Medical Sciences* more than forty years ago. From Dr. Curtis's table it appears that the deaths from phthisis in Boston during the twenty-eight years, from 1821 to 1848 inclusive, were 1 in 5.76 of all deaths, or 17.36 per cent. Dr. Hayward, from an examination of the statistics of New York for thirty years prior to 1850, gives the proportion in that city at 1 in 5.54, or about 18 per cent.

Dr. E. M. Snow, of Providence, R. I., in his valuable Notes on the Causes of Death in City Registrar's Report, 1881, gives an average percentage for twenty-six years, 1856–1881 inclusive, of 16.69 per cent. According to my figures, for the twenty-five years ending December 31, 1882, the average death-rate from consumption has been 1 in 285 of the whole population, or 3.77 in each thousand persons. Dr. Snow gives the average death-rate in Providence for the twenty-seven years, 1855–1881 inclusive, as 1 in 317, a considerable decrease over the average annual rate for the fifteen years, 1840–1854 inclusive, which was 1 in every 209 inhabitants.

The following table (pertaining to the city of Newburyport) shows the ratio of mortality from consumption among the native population for five periods during the past twenty-five years. The ratio of mortality among the foreign population is also shown; by comparing the latter statistics with the former, it will be seen that the death-rate from consumption among persons of foreign parentage is far in excess of that of the native population. The foreign population of Newburyport is estimated at 3000; it is, however, prepremised that the foreign element of any community is very variable and fluctuating, especially in manufacturing towns, where seasons of great business activity alternate with seasons of great depression. There have been years when the mortality from phthisis among foreigners has been very great, as in 1879; years when there has been an unusual influx of foreigners, chiefly Irish and French Canadians, who, bringing to this country constitutions enfeebled by hardship and privation, fell easy victims to the rigor of our climate. It is not an uncommon experience for physicians to record two and even three deaths from consumption in the same family and in the same season, nor is it unusual for parents coming originally from Ireland, and free from all hereditary tendencies to consumption, to witness their sons and daughters succumb, one after another, to the same disease.

POPULATION OF AMERICAN PARENTAGE.

1858..... one death from consumption in 370.
1865..... one death from consumption in 564.
1870..... one death from consumption in 252.
1875..... one death from consumption in 300.
1880..... one death from consumption in 351.

POPULATION OF FOREIGN PARENTAGE.

1858..... one death from consumption in 273.
1865..... one death from consumption in 150.
1870..... one death from consumption in 161.
1875..... one death from consumption in 176.
1880..... one death from consumption in 136.

Yearly average among persons of American parentage, one death from consumption in 336. Yearly average among persons of foreign parentage, one death from consumption in 179.

The lesson taught by these tables is that consumption is far more prevalent among foreiguers than among natives; as far as the latter are concerned there is a gradual decrease in the death-rate from this disease. This truth is still more apparent from Dr. Snow's carefully prepared statistics for a similar term of years; any difference in details being (possibly) explicable in part by the fact that the climate of Newburyport and of sea-port towns generally in this State is somewhat more severe and changeable than the climate of Providence, and as a consequence is more trying to foreigners.

POPULATION OF AMERICAN PARENTAGE (PROVIDENCE, R. I.).

1856..... one death from consumption in 268.
1865..... one death from consumption in 310.
1875..... one death from consumption in 415.
1880 ..... one death from consumption in 435.

POPULATION OF FOREIGN PARENTAGE.

1856..... one death from consumption in 262.
1865..... one death from consumption in 248.
1875..... one death from consumption in 288.
1880..... one death from consumption in 268.

The words "native population" in the above tables refer to decedents of American parentage, not always, however, acclimated to the locality where they died. In fact, reference to the mortality records shows that many of these decedents were comparatively strangers to the locality, immigrating from homes more or less distant. Persons, for instance, coming from inland regions often find our east winds and fierce northwesters very trying; any latent predispositions to phthisis are very likely to be awakened, especially if there be much exposure to our chilling spring weather.

The relative infrequency of consumption among the descendants of families that have for many generations been fixed to the soil is a conspicuous fact. Such families, for instance, largely of Puritan stock, as the Littles, the Lunts, the Spaldings, the Withingtons, the Moodys, the Pikes, the Lowells, the Woods, the Simpsons, the Stones, the Pettingills. I have inquired concerning the mortality records of all these families, and many more, indigenous (if I may so speak) to this region, and find consumption almost unknown for many generations.

In the struggle for existence the strongest and fittest survive. Nature by a process of selection gradually weeds out the sickly and infirm, — those not adapted to their conditions, — letting only those live who by inherent vitality can successfully cope with the difficulties of their environment. This truth is exemplified in the history of consumption in New England. The native race is becoming more hardy (at least in respect to resistance of severities of climate), while immigration is furnishing, and will long continue to furnish, the customary quota of deaths from consumption.

In another number I purpose to discuss the subject of causes.

RECENT PROGRESS IN THEORY AND PRACTICE OF MEDICINE.[1]

BY GEORGE B. SHATTUCK, M. D.

THE HYGIENIC TREATMENT OF ALBUMINURIA.

SENATOR delivered lately a lecture on this subject before the Berlin Medical Society,[2] which derives its value less from any novelty of the remarks than from the authority of the speaker in regard to renal disorders. Senator's conclusions are confirmatory of the best American and English writers' recommendations as to the treatment of albuminuria. After reminding the reader that the albuminuria is a symptom and measure of a disease, not a disease itself, that the amount of albumen lost — two and a half drachms daily being a very large amount — is not serious, though the local effect of its passage through the renal tissues is very possibly injurious, and alluding to the generally recognized inadequacy of drugs in chronic albuminuria, Senator takes up the various points of hygienic treatment which offer hope at least of alleviation and prolonged comparative health, and among such emphasizes especially the following: (1.) The question of the nourishment of patients with nephritis should include a consideration of the influence exercised upon the albuminuria both by the condition of the digestive process itself and by the character of the nourishment. (2.) The rule may be accepted in general that with albuminuria the wants of the system should be supplied rather by frequent small quantities of food than by larger amounts at longer intervals. (3.) Eggs should be forbidden; meat and cheese used sparingly, and of meats preferably veal or poultry; fish is to be recommended; fruit and vegetables are indicated, but the leguminous varieties less so; the use of fat is to be governed by the state of the digestion; spiced, smoked, and salted viands are unsuitable; red wine may be used moderately; beer, spirits, and the heavier wines are to be avoided; a milk diet is extremely useful, but that it may be sufficiently prolonged bread or some similar addition should be made. (4.) Saline or alkaline, — saline waters, warm or cold, according to the case, are found practically to act favorably, and this probably by effect upon the digestion and composition of the blood, as theoretically they should be a renal irritant; saline baths are useful through their congestive and stimulating effect upon the skin. (5.) Muscular exertion should be very restricted. (6.) An even body temperature should be sought by clothing, by climate, by retirement to bed if necessary. For clothing flannel should be worn next the skin; for a climate a warm and dry one should be selected, free from sudden changes, with a mean temperature from 60° F. to 70° F. (7.) Psychical influences are of great importance in this condition. (8.) With women during menstruation the amount of albumen excreted is always increased, and they should during that period be confined strictly to bed.

RENAL INADEQUACY.

Dr. Andrew Clark, president of the London Clinical Society, and the medical adviser of Mr. Gladstone, delivered a very readable address[1] on the above subject a few weeks since, before a meeting of medical men, which contains some valuable hints even for physicians not practicing in the land *par excellence* of beef, beer, and port wine. Under the head of Renal Inadequacy Dr. Clark places a class of cases, which in some measure he ventures to separate entirely from Bright's disease, in which the kidney, without any sensible alteration of structure that modern means of investigation will enable us to determine, cannot produce a healthy urine. Such kidneys produce a urine which, assuming the quantity to be a quantity of health, is low in density, and is deficient in solid constituents, principally the constituent of urea and its congeners. This condition may be regarded as a very early stage of Bright's disease, but the writer thinks it of practical value to recognize by a distinct name a state which may remain as it is during the whole period of life, which is nevertheless capable of removal, and which if unnoticed may lead to serious injury to the patient.

Such patients are characterized by three things particularly: (1.) By a curious inability to properly repair damages done to them either by accident or by disease. (2.) They not only repair damages slowly, but are peculiarly vulnerable; they catch cold, for example, easily, and get rid of it with difficulty. (3.) One can never be sure of the result of the performance of an ordinary surgical operation upon them; they die from a simple operation by hæmorrhage, or [illegible] an ordinary abscess opened and become pyæmic.

Dr. Clark confesses that he knows of no symptoms in the early stage whereby these cases can with certainty be detected, but says in general, "When you get hold of a patient who is ill, suffering from dyspepsia or nervousness, having headaches, and complaining of malaise and weakness, who cannot sleep well, who cannot do his work very well, examine his urine, and if you find that the urine is low in density you had better proceed a little further, and be very precise, and get the urine of twenty-four hours, and if you find that it is under fifty ounces in quantity, that it has not a specific gravity of 1010, and that the urea in it is deficient in amount, — under two per cent., — then whether there be albumen in the urine or not, whether there be any casts or not, whether there be granular débris deposited or not, you may know with certainty that the kidney is not doing its duty."

It may not be that this defect is the cause of the patient's ill health, but if it is found in addition that an increase of food makes the patient worse, and that, within certain limits, a diminution of food makes him better, there need be little doubt of it. As these cases of renal inadequacy progress if they be not well managed, that is, if the management be not adjusted to the fact that they are chimneys being choked, and that a roaring fire cannot be kept on, they develop exceedingly characteristic symptoms, symptoms so like those observed in myxœdema that they can scarcely be distinguished. Dr. Clark cites two autopsies on patients who presented the symptoms of renal inadequacy, one in the earlier, one in the later, stages, in which none of the gross appearances of renal disease were present.

In the way of prognosis it may be said in regard to these cases that if care be taken, if compensation be made for the defective kidney, they probably may go on indefinitely, that is, they may reach the full term of life allotted to man.

Treatment should consist in close attention to simple physiological laws and careful adherence to such rules in regard to diet, clothing, temperature, and exercise as are generally laid down for chronic albuminuria.

PAROXYSMAL HÆMOGLOBINURIA.

Dr. Saundby[2] sums up a paper on this subject as follows: —

(1.) Paroxysmal hæmoglobinuria occurs at all ages, but most commonly in young persons.

(2.) It affects both sexes, but males more frequently than females.

(3.) It is in some cases distinctly hereditary.

(4.) The exciting cause of an attack is almost invariably a chill, though in a few cases the first attack has undoubtedly been induced by a blow, yet the subsequent attacks have been brought on by exposure to cold.

(5.) Its relation to ague is exceptional, and not well made out.

(6.) It is not specially associated with any known diathetic tendency (for example, rheumatism, gout, scrofula), or with any specific disease (for example, syphilis).

(7.) There is strong reason to believe that functional disturbance of the liver is present in many cases.

(8.) Enlargement of the spleen has been noted, but is exceptional.

(9.) During attacks the temperature may vary from normal, or even subnormal, to a high degree of fever (105° F.).

(10.) The skin may be covered by profuse perspiration, or this may be restricted to certain parts, or it may be dry.

(11.) The skin may be jaundiced or of a peculiar dusky hue during and after the attacks.

(12.) The serum of the blood during the attacks has been shown to contain hæmoglobin (Hayem).

(13.) The microscopical characters of the blood are those of slight anæmia.

(14.) The urine during the attacks always contains hæmoglobin or met-hæmoglobin, serum, albumen, paraglobulin, granular and hyaline casts, and urates.

(15.) The urine between the attacks may contain traces of albumen or hæmoglobin, or both.

(16.) The prognosis as to recovery from each attack is good, no fatal case having occurred.

(17.) While a spontaneous cure has been recorded, as a rule the liability to relapses persists.

(18.) No drug influences the liability to relapse, but during the paroxysms quinine has seemed of most service.

(19.) Residence in a tropical climate affords the best prospect of warding off future attacks.

Dr. Isidor Boas summarizes the results of his study of paroxysmal hæmoglobinuria as set forth in his inaugural dissertation at Halle[3] as follows: (1.) Paroxysmal hæmoglobinuria is a disease *sui generis*, and to be distinctly separated from all other kinds of hæmo-

globinuria. (2.) There is an ætiological moment for the separate attacks of paroxysmal hæmoglobinuria which need never be overlooked, — a chill of individual portions of the skin, especially of those most exposed, as of the hands, feet, nose, or ears. (3.) The separate paroxysms are proportional to the intensity of the general symptoms, and the coloring of the urine to the intensity and duration of the chill. (4.) The natural and artificially produced paroxysms are in respect to symptoms entirely alike. (5.) The disorganization of the red blood corpuscles and the discharge of the hæmoglobin in the plasma precede and the general symptoms follow. (6.) The cause of the tendency to change of equilibrium depends probably upon a diminished power of resistance of the red blood corpuscles in presence of an externally acting irritation. (7.) The dissolution of the red blood corpuscles takes place locally only at the points exposed to cold, and from there the débris reach the blood stream. (8.) The cause of this diminished power of resistance of the red blood corpuscles is in most cases obscure, in a few syphilis, and in others malaria may deserve attention. (9.) Treatment other than prophylaxis or that proper for syphilis or malaria is negative.

Dr. Boas does not seem to recognize cases in which over-exertion and not exposure to cold is the apparent cause of the paroxysmal attack.

DIAGNOSIS OF FLOATING KIDNEY.
